The family of β-defensins consists of small, cationic, cysteine-rich antimicrobial polypeptides. For a long time, β-defensins were merely considered as parts of the antimicrobial innate immune response against a wide variety of pathogens. Recently, research over the past few years has revealed that—in addition to their direct antimicrobial activity—β-defensins promote innate inflammatory and adaptive immune responses by interacting with CC-chemokine receptors like CCR2 and CCR6. Recently, we characterized mouse β-defensin 14 (mBD14, Defb14), an ortholog of human β-defensin 3 (hBD3, DEFB103). mBD14 is expressed in a variety of tissues, epithelial cells and CD11c⁺ dendritic cells (DCs). Furthermore, we described the chemotactic recruitment of CCR6-expressing cells through mBD14.3

Inflammation typically correlates with increased local expression of β-defensins, but in severe cases β-defensins can also be detected systemically. In relation to this expression pattern, it is interesting that inflammation is associated with an increased risk for cancer development, and that recent reports suggest a link between β-defensin expression and tumor progression. For instance, epidermal growth factor (EGF)-enhanced expression of hBD3 has been reported in oral carcinoma lesions.6 Such an intratumoral hBD3 chemoattracts tumor-associated macrophages (TAMs) into carcinoma lesions in a CCR2-dependent manner and stimulates the production of tumor-promoting cytokines like interleukin-8 (IL-8), which is known to be a pro-angiogenic factor.7

Considering a potential relationship between β-defensins and malignancy as well as our previous results demonstrating the pro-inflammatory properties of mBD14, we analyzed the expression pattern of mBD14 in fibrosarcoma tissues and its potential role during tumor development. Quantitative real-time PCR analysis of tumor biopsies revealed substantial expression of mBD14 in BFS-1 fibrosarcomas. Moreover, we identified tumor-infiltrating CD45⁺ hematopoietic host cells as a local source of mBD14. To analyze the influence of mBD14 expression on tumor growth we generated a BFS-1 cell line overexpressing the mature mBD14 protein fused to the Fc fragment of human IgG1 (mBD14:Ig). The mBD14:Ig fusion protein retains its biological activity (e.g., antimicrobial activity, chemotactic activity).6 Wild type, mBD14:Ig-expressing and control BFS-1 cells were intradermally inoculated into syngeneic C57BL/6 mice. Interestingly, overexpression of mBD14:Ig in BFS-1 cells resulted in significantly enhanced tumor growth in vivo, correlating with increased tumor vascularization, as demonstrated by immunohistochemical staining for the endothelial cell marker CD31 (PECAM-1). We found that while vascular-endothelial growth factor (VEGF) mRNA expression was not altered, CXCL2 mRNA expression was significantly increased in mBD14:Ig-expressing fibrosarcomas. These observations are in line with previous research showing that β-defensins (e.g., hBD2) are implicated in the stimulation of endothelial cell migration and tube formation.8

The mechanism of β-defensin-stimulated angiogenesis then comes into question. In our study, the monitoring of vascular cell sprouting during aortic ring assay experiments clearly demonstrated that stimulation with recombinant mBD14:Ig does not influence vascular outgrowth. Thus, we excluded direct effects of mBD14 on vascularization and hypothesized that there might be an angiogenesis-promoting cell population involved. To identify the cell population that might contribute to the mBD14:Ig-induced progression of tumor growth, we analyzed the cellular composition of tumor-infiltrating leukocytes (TILs). Surprisingly, the B220⁺/CD19⁺ cell population was the only cell compartment significantly increased in mBD14:Ig-expressing tumors, while no substantial difference in the frequency of

For many years, β-defensins were best known for their antimicrobial activity. However, β-defensins also exert immunomodulatory functions, such as the chemotactic recruitment of immune cells via chemokine receptors. We demonstrated that mouse β-defensin 14 recruits CCR6⁺ B cells into fibrosarcomas, resulting in enhanced angiogenesis and tumor development.
Consistently, the reduced recruitment of LTβR+ B cells into tumors in a CCR6-dependent manner. These B cells, expressing LTβR-ligands, activate LTβR on tumor cells, in turn promoting CXCL2 expression, enhanced angiogenesis and increased tumor growth.

In summary, recent research from us and others suggest that antimicrobial peptides like β-defensins play critical roles in the development and progression of numerous tumors. The detailed characterization of β-defensin expression patterns during tumor development will provide further insights into the mechanisms of tumor progression. Importantly, β-defensins appear to constitute a link between innate inflammatory immune reactions and the molecular and cellular mechanisms that promote tumor development.

Figure 1. The model that we propose—based on our results—postulates that mBD14, expressed by host-derived CD45+ hematopoietic cells, recruits activated B220+/CD19+ B cells into tumors in a CCR6-dependent manner. These B cells, expressing LTβR-ligands, activate LTβR on tumor cells, in turn promoting CXCL2 expression, enhanced angiogenesis and increased tumor growth.
