EXTENSIONS AND CONTRACTIONS OF THE LIE ALGEBRA OF $q$-PSEUDODIFFERENTIAL SYMBOLS ON THE CIRCLE

BORIS KHESIN†, VOLODYMYR LYUBASHENKO‡, AND CLAUDE ROGER

Abstract. We construct cocycles on the Lie algebra of pseudo- and $q$-pseudodifferential symbols of one variable and on their close relatives: the sine-algebra and the Poisson algebra on two-torus. A “quantum” Godbillon-Vey cocycle on (pseudo)-differential operators appears in this construction as a natural generalization of the Gelfand-Fuchs 3-cocycle on periodic vector fields. We describe a nontrivial embedding of the Virasoro algebra into (a completion of) $q$-pseudodifferential symbols, and propose $q$-analogs of the KP and KdV-hierarchies admitting an infinite number of conserved charges.

1. Introduction

The Lie algebra of symbols of pseudodifferential operators on the circle arises naturally in various contexts: it is a deformation of the Poisson algebra of functions on the two-dimensional torus, the phase space for the KP and KdV hierarchies, a generalization of the Virasoro algebra and of the Lie algebra of differential operators. The latter object appeared recently in conformal field theory under the name of $W_{\infty}$ algebra.

We start our consideration with the Poisson algebra $C^\infty(T^2)$ of smooth functions on a two-dimensional torus (with respect to the standard Poisson bracket on $T^2$). Various deformation of this object include the sine-algebras [18], algebras of differential and pseudodifferential operators [34], $q$-analogs of differential operators and (finite-dimensional) $gl(n)$-approximations.

In this paper we consider so called $q$-deformation of the Lie algebra of pseudodifferential operators $(\psi DO_q)$ on the circle. From the quantization point of view we consider in this paper the next link in the chain of deformations of the Poisson algebra to pseudodifferential operators and then to $q$-pseudodifferential operators. Our work is closely connected with Kassel’s paper [22] where $q$-analogs of the algebra of purely differential operators and of the corresponding cocycles were described.

The construction can be applied to the case of pseudodifferential operators in $\mathbb{C}^n$, where one has $2n$ outer derivations coming from commutations with $\log D_i$ and $\log x_i$ (see e.g. Dhumaduldaev [3]). However, the Poisson structures related to integrable systems single out the one-dimensional case.

Date: March 28, 2022; June 7, 1995.
†Research was supported in part by the NSF grant DMS-9307086.
‡Research was supported in part by the EPSRC research grant GR/G 42976.
Some of our results were generalised by Wambst [39], who calculated, in particular, the first cyclic cohomology group of the topological algebra of $q$-pseudodifferential symbols and found that our cocycles span linearly the whole group.

We propose a $q$-version of the Manin triple of differential and integral operators on the circle. The extension of this triple by the logarithm of the derivative operator ([26]) and by the corresponding central term was considered in detail in [23]. In the classical situation the corresponding (infinite dimensional) Lie-Poisson group is “unipotent” and equipped with the quadratic generalized Gelfand-Dickey Poisson structure. This structure is the main ingredient in the construction of the KP and $n$-KdV hierarchies ([10, 23]).

We show that the group of $q$-pseudodifferential operators is rather “solvable” than “unipotent”. Its exponential map is still well defined and surjective as in the classical case, but is not bijective. This allows to define $q$-analogs of the hierarchies which are now commuting flows having infinite number of conserved quantities on the space of $q$-pseudodifferential operators.

This paper is organized as follows. In the second Section we discuss the Poisson algebra on a torus and its approximations by finite dimensional algebras $u((m + 1)/2, (m – 1)/2)$. Section 3 is devoted to the description of various relations between the algebra of pseudodifferential operators, its $q$-analog, and the sine-algebra. In Section 4 we define a “$q$-logarithmic” outer derivation of the algebra and the corresponding cyclic 2-cocycle and (the Lie algebra 2-cocycle). We construct also quantum Godbillon–Vey cocycle and higher degree generalizations. They are defined for any $q \neq 0$ and depend on $q$ continuously. In Section 5 we study the behaviour of cocycles when the algebra is deformed. An embedding of the undeformed Virasoro algebra into an appropriately completed algebra of $q$-pseudodifferential operators is constructed in Section 6. The final Section 7 contains the construction of $q$-analogs of the KP and $n$-KdV hierarchies inspired by the previous formalism.

Acknowledgements. We are pleased to thank M. I. Golenishcheva-Kutuzova, A. N. Kirillov, M. V. Saveliev and A. M. Vershik for fruitful discussions. We also thank V. G. Kac and A. O. Radul for communicating us preliminary version of their work [21].

2. Deformations of the Poisson algebra on two-torus

Let $\mathbb{T}^2$ be the standard torus with $p,q$-coordinates equipped with a symplectic form $\omega = dp \wedge dq$, and $N = C^\infty(\mathbb{T}^2)$ be the Lie algebra of (periodic) functions in $p,q$ with respect to the Poisson bracket.

2.1. Low-dimensional Lie cocycles on $C^\infty(\mathbb{T}^2)$.

Theorem 2.1 (see, e.g. [28], [24]). The group $H^2_{\text{Lie}}(C^\infty(\mathbb{T}^2), \mathbb{R})$ is two-dimensional and is generated by the 2-cocycles

$$c_p(f, g) = \int_{\mathbb{T}^2} \{p, f\} g \omega = \int_{\mathbb{T}^2} \left( \frac{\partial f}{\partial q} \cdot g \right) \omega$$
\[ c_q(f, g) = \iint_{\mathbb{T}^2} (\{q, f\} g) \omega = -\iint_{\mathbb{T}^2} \left( \frac{\partial f}{\partial p} \cdot g \right) \omega, \]

where \( f, g \in N = C^\infty(\mathbb{T}^2) \).

Remark 2.1. The linear functions \( p \) and \( q \) are being considered as multivalued functions on \( \mathbb{T}^2 \). They define Hamiltonian vector fields which “shift the mass center” of \( \mathbb{T}^2 \) unlike the fields corresponding to univalued Hamiltonians.

More generally (see [28]) on an arbitrary compact symplectic manifold \((M, \omega)\) the Poisson algebra of functions \( C^\infty(M) \) has the universal central extension of dimension \( b_1 = \dim H_1(M, \mathbb{R}) \) (i.e. \( H^2_{\text{Lie}}(C^\infty(M), \mathbb{R}) \cong H_1(M, \mathbb{R}) \)).

**Theorem 2.2.** The group \( H^3_{\text{Lie}}(C^\infty(\mathbb{T}^2), \mathbb{R}) \) is at least two-dimensional. Nontrivial 3-cocycles can be defined as follows:

\[ c_0(f, g, h) = \iint_{\mathbb{T}^2} (\{f, g\} h) \omega \]

and

\[ c_1(f, g, h) = \text{Alt}_{f, g, h} \iint_{\mathbb{T}^2} \left( \frac{\partial^3 f}{\partial p^3} \frac{\partial^3 g}{\partial q^3} - 3 \frac{\partial^3 f}{\partial p^2 \partial q} \frac{\partial^3 g}{\partial q^2 \partial p} + 3 \frac{\partial^3 f}{\partial p \partial q^2} \frac{\partial^3 g}{\partial q \partial p^2} - \frac{\partial^3 f}{\partial q^3} \frac{\partial^3 g}{\partial p^3} \right) h \cdot \omega, \]

where \( f, g, h \in N \).

Remark 2.2. One of the most important features of the algebra \( C^\infty(\mathbb{T}^2) \) is the existence of an ad-invariant pairing (Killing form): \( \langle f, g \rangle = \iint_{\mathbb{T}^2} (f \cdot g) \omega \). This allows one to describe the above cocycles in the following alternative way.

To prove Theorem 2.2 we introduce a map \( \theta \) which we are going to exploit intensively in Section 4:

\[ \theta : C^k(N, N) \rightarrow C^{k+1}(N, \mathbb{R}) \]

(\( C^k(N, V) \) stands for the additive group of \( V \)-valued \( k \)-cochains on \( N \)). Namely, \( \theta(c)(f_1, \ldots, f_{k+1}) = \text{Alt}_{f_1, \ldots, f_k+1} \langle c(f_1, \ldots, f_k), f_{k+1} \rangle \). Here and below \( \text{Alt} \) denote the sum over all shuffles of arguments with the corresponding signs (in the case above the sum consist of \( (k + 1) \) summands due to skewsymmetry of \( c \)).

**Lemma 2.3.** Let \( c \in Z^k(N, N) \) be a closed cochain such that

\[ \text{Alt}_{f_1, \ldots, f_{k+2}} \langle \{f_1, f_2\}, c(f_3, \ldots, f_{k+2}) \rangle = 0 \] (sum over \((k + 2)(k + 1)/2 \) summands). Then \( \theta(c) \in Z^{k+1}(N, \mathbb{R}) \).

**Proof.** The exterior product of the identity cochain \( b = (\text{id} : N \rightarrow N) \in C^1(N, N) \) with \( c \) gives a cochain in \( C^{k+1}(N, N \otimes N) \)

\[ (b \boxtimes c)(f_1, \ldots, f_{k+1}) = \text{Alt}_{f_1, \ldots, f_{k+1}} f_1 \otimes c(f_2, \ldots, f_{k+1}). \]
Its coboundary is

\[ d(b \boxtimes c) = db \boxtimes c - b \boxtimes dc = db \boxtimes c = \{ , \} \boxtimes c \]

\[
(\{ , \} \boxtimes c)(f_1, \ldots, f_{k+2}) = \text{Alt}_{f_1, \ldots, f_{k+2}} \{ f_1, f_2 \} \otimes c(f_3, \ldots, f_{k+2})
\]

since \( db \) is the bracket \( \{ , \} \) itself. Applying the homomorphism \( \langle , \rangle : N \otimes N \to \mathbb{R} \) we get the cochain \( N \) the algebra \( \mathbb{C} \), and

\[
d(\theta)(f_1, \ldots, f_{k+2}) = \text{Alt}_{f_1, \ldots, f_{k+2}} \langle \{ f_1, f_2 \}, c(f_3, \ldots, f_{k+2}) \rangle
\]

which vanishes by assumption.

\[
\text{Example 2.1.} \text{ Denote by } \xi_p \in H^1(N, N) \text{ (resp. } \xi_q) \text{ the following outer derivation of the algebra } N: \xi_p(*) = \{ p, * \} : N \to N \text{ (resp. } \xi_q(*) = \{ q, * \}). \text{ Then the 2-cocycle } c_p = \theta(\xi_p) \text{ (resp. } c_q = \theta(\xi_q)) \text{ is } c_p(f, g) = \langle \xi_p(f), g \rangle \text{ (resp. } c_q(f, g) = \langle \xi_q(f), g \rangle). \text{ The condition } (2.1) \text{ follows from the skew-symmetry of } \xi_p.\
\]

\[
\text{Example 2.2.} \text{ The wedge product } d_0 = \xi_p \wedge \xi q = \{ , \} \text{ is an } N \text{-valued 2-cocycle. The property } (2.1) \text{ holds by the Jacobi identity. And it is easy to see, that } \theta(d_0)(f, g, h) = c_0(f, g, h). \text{ Note that even though } d_0 \text{ is a trivial 2-cocycle (i.e. is a 2-coboundary), its image under the homomorphism } \theta \text{ is a nontrivial 3-cocycle on } N. \text{ The 2-cocycle } d_0 \text{ corresponds to the deformation of } N \text{ evolved by a dilation of the area form } \omega.
\]

In the Section 4 we extend this construction to the algebras of pseudodifferential operators and to their \( q \)-analogues.

A common feature of these examples is the notion of invariant cocycle on a Lie algebra with an ad-invariant form. This notion (defined and intensively used in [29]) generalizes naturally the idea of skew-symmetric 1-cocycle. Let \( g \) be a Lie algebra with an ad-invariant form \( \langle , \rangle \), one says that a cocycle \( c \in C^k(g, g) \) is invariant if the map \( \theta'(c) \) defined through \( \theta'(c)(x_0, \ldots, x_k) = \langle c(x_0, \ldots, x_{k-1}), x_k \rangle \) is antisymmetric. One checks easily that invariant cocycles form a subcomplex in \( C^*(g, g) \) (denoted by \( C^*_I(g, g) \)), and \( \theta' \) (proportional to \( \theta ) \) defines a morphism of complexes:

\[ \theta' : C^k_I(g, g) \to C^{k+1}(g, \mathbb{R}). \]

So one has naturally the notion of invariant cohomology denoted \( H^k_I(g, g) \) with a map still denoted by \( \theta' \)

\[ \theta' : H^k_I(g, g) \to H^{k+1}(g, \mathbb{R}). \]

Notice that the cohomology class of \( d_0 = [ , ] \) is nontrivial in \( H^2_I(g, g) \), but is trivial in \( H^2(g, g) \). The same phenomenon occurs for semisimple classical Lie algebras: the Lie bracket defines a nontrivial element in \( H^2_I(g, g) \) whose image in \( H^3(g, \mathbb{R}) \) generates the latter group (see e.g. Section 2.2).

\[
\text{Example 2.3.} \text{ The 3-cocycle } c_1 \text{ is obtained by the same homomorphism } \theta' \text{ from a non-trivial 2-cocycle } d_1 \in H^2(N, N); d_1 = \frac{\partial \phi}{\partial p} \frac{\partial \phi}{\partial q} - 3 \frac{\partial \phi}{\partial p} \frac{\partial \phi}{\partial q} \frac{\partial \phi}{\partial p} + 3 \frac{\partial \phi}{\partial q} \frac{\partial \phi}{\partial p} \frac{\partial \phi}{\partial p} - \frac{\partial \phi}{\partial q} \frac{\partial \phi}{\partial p} \frac{\partial \phi}{\partial p}. \text{ This cocycle } d_1 \text{ is responsible for a formal deformation of the Poisson algebra; in fact, it is the...}
third term of the Moyal deformation (called also deformation quantization) of the Poisson algebra $N$, obtained by extending the Heisenberg law $\{p, q\} = 1 \rightarrow [\hat{p}, \hat{q}] = Id$. Another notation for this cocycle is $d_1(f, g) = (\mu \nabla^3) (f \otimes g)$ (here $\nabla = (\frac{\partial}{\partial p} \otimes \frac{\partial}{\partial q} - \frac{\partial}{\partial q} \otimes \frac{\partial}{\partial p})$ and $\mu$ denotes the multiplication). One checks easily that this cocycle is invariant: if one uses trigonometric representation for functions on $\mathbb{T}^2$, say $L_\alpha = -\exp (i (\alpha_1 q + \alpha_2 p))$, $\alpha \in \mathbb{Z}^2$, then

$$\int_{\mathbb{T}^2} d_1(L_\alpha, L_\beta)L_\gamma \omega = \delta_{\alpha + \beta + \gamma, 0} (\alpha \times \beta)^3,$$

where $\alpha \times \beta = \alpha_2 \beta_1 - \alpha_1 \beta_2$. Invariance is then immediate. Linear independence of the classes of $c_0$ and $c_1$ in $H^3(N, \mathbb{R})$ can be also checked through this formula. Nontriviality of these 2-cocycles is equivalent to nontriviality of the corresponding Lie algebra deformation (see, e.g. [9]).

**Remark 2.3.** The cohomology class of $d_1$ in $H^2(N, N)$ is sometimes called the Vey class after Vey’s fundamental contribution to the subject [38]. It admits a global analogue for any symplectic manifold, and is often denoted by $S^3_\Gamma$. This Moyal deformation is linked with symbols of differential operators via the Weyl ordering. For arbitrary surfaces the invariance of that cocycle is conjectured, but to the best of our knowledge has not been proved yet.

I. Gelfand and O. Mathieu [12] found a nice construction of higher cocycles of the Poisson algebra $N$. We generalize them to the algebras of pseudodifferential or $q$-pseudodifferential operators and sine-algebras discussed below. This approach can be explained through the following approximation scheme.

### 2.2. Approximation of $N = C^\infty(\mathbb{T}^2)$ by $gl(m)$ as $m \to \infty$. (following [18]).

Let us fix some odd $m$ and consider the following two unimodular matrices in $gl(m)$:

$$E \equiv \begin{pmatrix} 1 & \varepsilon & 0 \\ \varepsilon & 0 & \ddots \\ 0 & \ddots & \varepsilon^{m-1} \end{pmatrix} \quad \text{and} \quad H \equiv \begin{pmatrix} 0 & 1 & 0 \\ \ddots & \ddots & \ddots \\ 0 & 1 & 0 \\ 1 & 0 \end{pmatrix}$$

where $\varepsilon$ is a primitive $m^{th}$ root of unity (say, $\exp \left(\frac{4\pi i}{m}\right)$). They obey the identities $HE = \varepsilon EH, E^m = H^m = 1$. Then the unitary unimodular matrices

$$\mathcal{J}(k_1, k_2) = \varepsilon^{k_1 k_2 / 2} E^{k_1} H^{k_2}$$

span the algebra of $gl(m)$. Note that $\mathcal{J}^{-1}(k_1, k_2) = \mathcal{J}_{-(k_1, k_2)}$ and $\text{tr} \mathcal{J}(k_1, k_2) = 0$ except for $k_1 = k_2 = 0 \pmod{m}$. The set of $\mathcal{J}$’s is closed under multiplication:

$$\mathcal{J}_k \mathcal{J}_\ell = \varepsilon^{k \times \ell / 2} \mathcal{J}_{k+\ell} \quad (k = (k_1, k_2), \ell = (\ell_1, \ell_2), k \times \ell = k_2 \ell_1 - k_1 \ell_2).$$
Therefore \( \{ \mathcal{J}_k \} \) satisfy the commutation relations

\[
[\mathcal{J}_k, \mathcal{J}_\ell] = 2i \sin \left( \frac{2\pi (k \times \ell)}{m} \right) \mathcal{J}_{k+\ell} \tag{2.3}
\]

The real subalgebra \( \mathfrak{a}(m) \) of \( gl(m) \) spanned by \( i\mathcal{J}_k \) is isomorphic to \( u((m+1)/2) \times u((m-1)/2) \), the Lie algebra of the group of matrices unitary with respect to hermitian metric in \( \mathbb{C}^m \) with \((m+1)/2\) positive and \((m-1)/2\) negative squares. Indeed,

\[
(-1/m) \, \text{Tr}(i\mathcal{J}_k \cdot i\mathcal{J}_l) = \delta_{k+l,0},
\]

which implies that the signature of the Killing form on \( \mathfrak{a}(m)/\mathbb{R}\mathcal{J}_0 \) is 0. For \( su(k,l) \) this signature is \((k-l)^2 - 1\).

As \( m \to \infty \) this algebra goes to the algebra \([L_k, L_\ell] = (k \times \ell) L_{k+\ell}\) through the identification \((m/4\pi i) \mathcal{J}_k \mapsto L_k \). The latter object is exactly the Poisson algebra of Hamiltonian functions on \( \mathbb{T}^2 \):

\[
L_{(k_1,k_2)} = - \exp \left( i \left( k_1 q + k_2 p \right) \right),
\]

which is modulo constants the same as the algebra of the corresponding Hamiltonian vector fields:

\[
L_{(k_1,k_2)} = i \exp \left( i \left( k_1 q + k_2 p \right) \right) \left( k_1 \frac{\partial}{\partial p} - k_2 \frac{\partial}{\partial q} \right).
\]

The algebra (2.3) is a non-extended case ("cyclotomic family") of an infinite dimensional "sine-algebra" [5, 6, 7]:

\[
[\mathcal{J}_k, \mathcal{J}_\ell] = r \sin(2\pi (k \times \ell)/\lambda) \mathcal{J}_{k+\ell} + (a \cdot k) \delta_{k+\ell,0} \tag{2.4}
\]

where the constant \( \lambda \) is not necessarily integer, but is an arbitrary complex number, \( a = (a_1, a_2) \) is a fixed plane vector, \( r \in \mathbb{C} \), \( k = (k_1, k_2) \), \( \ell = (\ell_1, \ell_2) \) are not integers modulo \( m \), but belong to \( \mathbb{Z}^2 \), and \((a \cdot k) = a_1 k_1 + a_2 k_2\).

Unlike the (simple) \( sl(m) \) algebra, the (infinite dimensional) sine-algebra and the Poisson algebra \( \{ L_k \} \) have two nontrivial central extensions. Thus 2-cocycles on the sine-algebra with an arbitrary \( \lambda \) disappear when we truncate it to the finite-dimensional object. However, the situation with real- (or complex-) valued 3-cocycles is different. It is well-known that the algebra \( su((m+1)/2, (m-1)/2) \) as any simple Lie algebra has a 1-dimensional group \( H^3(su((m+1)/2, (m-1)/2), \mathbb{R}) \).

**Proposition 2.4.** The Lie 3-cocycle on \( u((m+1)/2, (m-1)/2) \) generating \( H^3_{\text{Lie}}(u((m+1)/2, (m-1)/2), \mathbb{R}) \) goes to the 3-cocycle \( c_0 \) (up to a multiplicative constant) of Theorem 2.2 as \( m \to \infty \).

**Proof.** The cocycle on \( \mathfrak{a}(m) \) is given by the completely antisymmetric expression \( \mu(A, B, C) = a \, \text{Tr}([A, B]C), \ a = (4\pi i)^2 m^{-3} \). Note, that due to a nondegenerate pairing on \( \mathfrak{a}(m) \): \( \langle A, B \rangle = \text{Tr}(AB) \) the cocycle \( \mu \) can be obtained from an invariant 2-cocycle \( \eta \in Z^2(\mathfrak{a}(m), \mathfrak{a}(m)) \): \( \eta(A, B) = [A, B] \) via \( \theta(\eta) = \mu \) (see Section 2.1). As \( m \to \infty \) the commutator of matrices \([ \cdot , \cdot ]\) goes to the Poisson bracket, and \( a \, \text{Tr}(\cdot) \) goes to the
ad-invariant trace on \( N \) defined by \( \text{Tr}(f) = \int_{T^2} f \omega \). Indeed, \([L_f, L_g] = L_{\{f,g\}}\), and in the limit the trace becomes the zero Fourier mode of a Hamiltonian function.  

The coordinate expressions of the cocycles are

\[
\mu(J_\alpha, J_\beta, J_\gamma) = \frac{m}{2\pi} \sin \left( \frac{2\pi(\alpha \times \beta)}{m} \right) \delta_{\alpha+\beta+\gamma,0}
\]

\((\alpha, \beta, \gamma \text{ are mod } m)\), and

\[
c_0(L_\alpha, L_\beta, L_\gamma) = (\alpha \times \beta) \delta_{\alpha+\beta+\gamma,0}
\]

3. Adjacency diagram of the algebras \( C^\infty(T^2), \sin_\lambda, \psi DO, \psi DO_q \)

In the preceding section we showed that the 3-cocycle on \( u((m+1)/2, (m-1)/2) \) survives under the limit \( m \to \infty \). In the next section we will see how it deformes when one quantizes the Poisson algebra \( N \) into \( \psi DO \) or \( \psi DO_q \).

The diagram of various algebras discussed in this paper is as follows

\[
\begin{array}{ccc}
\rule{0pt}{2.5ex} & u((m+1)/2, (m-1)/2) & \leftarrow \sin_\lambda & \rightarrow \psi DO_q \\
\downarrow m \to \infty \swarrow & C^\infty(T^2) & \downarrow \lambda \to \infty & \downarrow q \to 1 \\
\{ \cdots \} & \psi DO
\end{array}
\]

In this section we define all the objects and meaning of all arrows in this diagram. We recall also certain well- and less-known facts about the objects involved.

3.1. Algebras \( u((m+1)/2, (m-1)/2) \) and \( \sin_\lambda \). In the last section it was mentioned that the limit \( m \to \infty \) of the structural constants of \( u((m+1)/2, (m-1)/2) \), is to be considered in the framework of generic infinite dimensional sine-algebras \( \sin_\lambda \) (with rational or irrational \( \lambda \)):

\[
[J_k, J_\ell] = \frac{\lambda}{2\pi} \sin \left( \frac{2\pi(k \times \ell)}{\lambda} \right) J_{k+\ell}.
\]

3.2. Algebra of pseudodifferential operators on the line and on the circle.

The algebra of \( \psi DO \) is a quantization of the algebra \( N = C^\infty(T^2) \) where \( q \) is replaced by \( x \) and \( p \) is replaced by \( \frac{\partial}{\partial x} \). More formally,

**Definition 3.1.** A ring \( \psi DO \) of pseudodifferential symbols is the ring of formal series

\[
A(x, \partial) = \sum_{n=0}^\infty a_n(x) \partial^n
\]

with respect to \( \partial \), where \( a_n(x) \in C[x, x^{-1}] \) (or \( C^\infty(S^1, \mathbb{R} \text{ or } \mathbb{C}) \)), and the variable \( \partial \) corresponds to \( d/dx \). The multiplication law in \( \psi DO \) is given by the commutation relations

\[
\partial \circ f(x) = f(x) \partial + f'(x)
\]

\[
\partial^{-1} \circ f(x) = f(x) \partial^{-1} - f'(x) \partial^{-2} + f''(x) \partial^{-3} - \ldots
\]
These relations define the usual composition law on the subalgebra $DO \subset \psi DO$ of differential operators (i.e. on polynomials with respect to $\partial$) and they can be unified in one as

$$\partial^s \circ u(x) = \sum_{\ell \geq 0} \binom{s}{\ell} u^{(\ell)}(x) \partial^{s-\ell},$$

(3.1)

where $\binom{s}{\ell} = \frac{s(s-1)\cdots(s-\ell+1)}{\ell!}$. The product determines the natural Lie algebra structure on $\psi DO$: $[A, B] = A \circ B - B \circ A$. The space $\psi DO$ with this Lie algebra structure will be denoted by $G$.

Moreover, there are operators $\text{res}: \psi DO \to \mathbb{C}[x, x^{-1}]$ (or $C^\infty(S^1)$) and $\text{Tr}: \psi DO \to \mathbb{C}$ on the ring $\psi DO$: $\text{res} \left( \sum a_i D^i \right) = a_{-1}(x)$, and $\text{Tr} A = \int \text{res} A$. The main property of $\text{Tr}$ is $\text{Tr} [A, B] = 0$ for arbitrary $A, B \in \psi DO$ (here and below we integrate over the circle $S^1$).

Remark 3.1. The multiplication formula above is defined not only for integer values of $s$, but for fractional and complex values as well. One can define an associative product on $\psi DO$ depending on a parameter $h$. The Leibnitz rule for multiplication of symbols in $\psi DO$ gives the following general formula equivalent for $h = 1$ to the rule (3.1) above:

$$A(x, \xi) \circ_h B(x, \xi) = \sum_{n \geq 0} \frac{h^n}{n!} A^{(n)}_\xi(x, \xi) B^{(n)}_x(x, \xi)$$

where $A^{(n)}_\xi = \frac{d^n}{d\xi^n} A(x, \xi)$, $B^{(n)}_x = \frac{d^n}{dx^n} B(x, \xi)$. Let $\Phi_t : \mathfrak{G} \to \mathfrak{G}$ defined through $\Phi_t(a(x)\xi^p) = a(x)t^{p-1}\xi^p$ be a family of bijective maps for $t \in [0, 1]$, singular for $t = 0$. Set $[A, B]_t = [\Phi_t(A), \Phi_t(B)]$. One has $[A, B]_t = [A, B] + t \ldots$. So when $t \to 0$ \lim$[A, B]_t = [A, B]$. One says that the commutator of pseudodifferential symbols contracts onto the Poisson bracket.

3.3. The algebra of $q$-pseudodifferential symbols.

3.3.1. Associative algebra structure. The notion of the $q$-analog of the derivative (and any differential) operator (see, e.g., [22]) is extended here to the case of pseudodifferential operators. We follow the framework of the previous subsections stressing the difference between the classical and $q$-deformed case.

Let $F$ be the algebra $\mathbb{C}[x, x^{-1}]$ and $q \in \mathbb{C}^\times$. It will be the main algebra of coefficients for us, the reader can easily reproduce the results for the algebra $F' = C^\infty(S^1)$ in the case $q \in \mathbb{C}, |q| = 1$ etc. We use the following notations for $q$-numbers

$$(n)_q = \frac{q^n - 1}{q - 1}$$

$$\binom{m}{\ell}_q = \frac{(m)_q(m-1)_q\cdots(m-\ell+1)_q}{(1)_q(2)_q\cdots(\ell)_q}.$$
Define the $q$-analog of the derivative by the following
\[ D_q f(x) = \frac{f(qx) - f(x)}{q - 1} \]
for $f \in F$. It will be useful to define also the shift
\[ \tau f(x) = f(qx), \quad \tau^\beta f(x) = f(q^\beta x). \]
Clearly, $\tau$ commutes with $D_q$. So, $D_q$ is a $q$-derivative in the following sense:
\[ D_q (fg) = D_q(f)g + \tau(f)D_q(g). \]

**Definition 3.2.** An algebra $\psi DO_q$ of $q$-pseudodifferential operators is a vector space of formal series
\[ \psi DO_q = \left\{ A(x,D_q) = \sum_{i=0}^{\infty} u_i(x) D^i_q \mid u_i \in F \right\} \]
with respect to $D_q$. The multiplication law in $\psi DO_q$ is defined by the following rule: $F$ is a subalgebra of $\psi DO_q$ and there are commutation relations:
\[ D_q \circ u = (D_q u) + \tau(u) D_q, \quad u \in F \]
\[ D^{-1}_q \circ u = \sum_{k \geq 0} (-1)^k \left( \tau^{-k-1} (D^k_q u) \right) D^{-k-1}_q, \quad u \in F, F'. \] (3.2)

Each term of the product of two Laurent series in $D_q$ is found by applying these rules finite number of times. The formula (3.2) is built so that
\[ D^{-1}_q \circ D_q \circ u = D_q \circ D^{-1}_q \circ u = u. \]
For $q = 1$ these formulas recover the “classical” definition of multiplication law in the algebra of pseudodifferential operators $\psi DO$.

The commutation rule for $D^n_q$ (with any integer $n$) and $u(x)$ join these formulae in one:
\[ D^n_q \circ u = \sum_{\ell \geq 0} \binom{n}{\ell} \left( \tau^{n-\ell} (D^\ell_q u) \right) D^{n-\ell}_q. \] (3.3)

**Proposition 3.1.** The $q$-analog of the Leibnitz rule of multiplication of two $q$-pseudodifferential operators $A(x,D_q), B(x,D_q)$ can be written as the following operation on their symbols
\[ A(x,D_q) \circ B(x,D_q) = \sum_{k \geq 0} \frac{1}{(k)!} \left( \frac{d^k}{dD^k_q} A \right) \ast (D^k_q B) \] (3.4)
where $\frac{d^k}{dD^k_q} A(x,\xi)$ is the $q$-derivative of $A$ with respect to the second argument (for $A = f(x)D^n_q$ it is $\frac{d^k}{dD^k_q} A = \frac{d^k}{dD^k_q} (f D^n_q) = \frac{(\alpha)}{\alpha-k}! f D^{\alpha-k}_q$), and $D^k_q B(x,D_q)$ is the $q$-derivative of $B$ defined above, and finally, the multiplication $\ast$ of symbols is defined with the following commutation rule of the generators:
\[ f \ast D_q = f D_q, \quad D_q \ast f = \tau(f) D_q, \quad D^{-1}_q \ast f = \tau^{-1}(f) D^{-1}_q. \]
Proof. Straightforward verification of the formula (3.4) for the product \( D^n_q \circ u(x) \) gives the same answer as (3.3). \( \square \)

3.3.2. Non-commutative residue for \( \psi DO_q \).

1. The operation \( \text{res} : \psi DO_q \rightarrow F \) is defined by
   \[
   \text{res} \left( \sum_{i=-\infty}^{n} u_i(x) D^i_q \right) = u_{-1}(x)
   \]
   generalizing definition for classical pseudodifferential symbols [40].

2. The integral along the circle \( S^1 \) gives a linear functional \( \int : F \rightarrow \mathbb{C} \), \( \int x^n = \delta_{n,0} \), on the function algebra \( F \) satisfying \( \int D_q f = 0 \) and \( \int \tau(f) = \int f \) for all \( f \in F \). We have also an “integration by parts” formula \( \int f \tau^{-1}(D_q(g)) = -\int D_q(f)g \).

3.3.3. Inner product on \( \psi DO_q \).

Define in \( \psi DO_q \) the element \( T = (q-1)D_q + 1 \) and denote its inverse \( E \equiv T^{-1} = \sum_{i=1}^{\infty} \frac{(-1)^{i-1}}{(q-1)^i} D^{-i}_q \).

Lemma 3.2. The automorphism \( \tau : \psi DO_q \rightarrow \psi DO_q, fD^n_q \mapsto \tau(f)D^n_q \) is inner. Precisely, \( \tau(A) = TAT^{-1} = E^{-1}AE \).

Proof. Indeed, for any \( f \in F \)
\[
TfT^{-1} = ((q-1)D_q + 1)fT^{-1}
= \{(q-1)(\tau(f)D_q + D_q(f)) + f\}T^{-1}
= \{\tau(f)((q-1)D_q + 1) + (q-1)D_q(f) - \tau(f) + f\}T^{-1}
= \tau(f)TT^{-1} = \tau(f)
\]
and \( T \) commutes with \( D_q \). \( \square \)

Define the Lie algebra \( \mathfrak{G}_q \) as the set \( \psi DO_q \) of all \( q \)-pseudodifferential symbols equipped with the commutator bracket \([A,B] = A \circ B - B \circ A\).

Theorem 3.3. The bilinear form \( \langle A, B \rangle = \int \text{res}(ABE) \) is an ad-invariant symmetric non-degenerate form on the Lie algebra \( \mathfrak{G}_q \).

To prove it consider the bilinear form \( (A, B) \mapsto \int \text{res}(A \circ B) \) on the algebra \( \psi DO_q \). It is not symmetric but it has the following symmetry property.

Proposition 3.4. For any \( A, B \in \psi DO_q \)
\[
\int \text{res}(A \circ B) = \int \text{res}(B \circ \tau(A)),
\]
where the map \( \tau : \psi DO_q \rightarrow \psi DO_q \) is the following automorphism of the algebra \( \psi DO_q \):
\[
\tau \left( fD^n_q \right) = \tau(f)D^n_q
\]
Proof. Explicitly the form \( \int \text{res} \) is given by
\[
\int \text{res} (f D_q^a \circ g D_q^b) = \int \text{res} \left( f \sum_{k \geq 0} \binom{a}{k} \tau^{-k}(D_q^k g) D_q^{a-k+b} \right) = \left( \frac{a}{a+b+1} \right) \int f \tau^{-b-1} (D_q^{a+b+1} g)
\]
for \( a + b + 1 \geq 0 \), and it vanishes otherwise. On the other hand assuming \( a + b + 1 \geq 0 \) we find also that
\[
\int \text{res} (\tau^{-1}(g) D_q^b \circ f D_q^a) = \left( \frac{b}{a+b+1} \right) \int \tau^{-1}(g) \tau^{-a-1}(D_q^{a+b+1} f)
\]
\[
= \frac{b(b-1) \ldots (-a)}{(a+b+1)!} \int \tau^{-b-1}(g) \tau^{-a-b-1}(D_q^{a+b+1} f)
\]
\[
= \frac{(-b)(-b+1) \ldots a}{(a+b+1)!} \int D_q^{a+b+1}(\tau^{-b-1} g) f
\]
which coincides with the expression above. \( \Box \)

Now Theorem 3.3 immediately follows from Lemma 3.2.

3.3.4. Twisted loop algebra. The algebra \( \psi DO_q \) can also be described as a twisted loop algebra following [21]. This construction, in short, is as follows.

For an associative algebra \( A \) and its automorphism \( \sigma \) one defines the twisted loop algebra \( A[\sigma^{-1}] \). As a vector space this is the space of Laurent polynomials \( \sum_{j \in \mathbb{Z}} x^j a_j, a_j \in F \). The associative product is defined by the rule:
\[
(x^m a)(x^n b) = x^{m+n} \sigma^n(a)b.
\]

Of course, when \( \sigma \) is the identity automorphism, one recovers the usual notion of the loop algebra. (Those algebras are purely algebraic versions of the well-known cross-product in functional analysis.)

With any trace \( Tr \) on \( A \) one can associate a central extension of \( A[\sigma^{-1}] \) defined by the following 2-cocycle:
\[
\psi_{\sigma,Tr}(x^m a, x^n b) = -\psi_{\sigma,Tr}(x^n b, x^m a) = Tr((1 + \sigma + \cdots + \sigma^{m-1})(\sigma^{-m}(a)b)) \delta_{m+n,0}
\]
if \( m \) is positive, and 0 if \( m = 0 \).

In order to obtain \( q \)-pseudodifferential symbols simply take \( A = \mathbb{C}[\xi, \xi^{-1}] \) and for some \( q \in \mathbb{C}^* \) set \( \sigma_q(\xi) = q \xi + 1 \) so that \( \sigma_q^n(\xi) = q^n \xi + (n)_q \).

We get then an isomorphism of associative algebras
\[
I : A_q[x, x^{-1}] \to \psi DO_q
\]
defined on generators as follows:
\[
I(x^n) = x^n \quad \text{and} \quad I(\xi) = D_q.
\]
In the particular case of \( q = 1 \), one recovers the associative algebra of pseudodifferential operators by assigning to \( \xi \) the operator \( f \mapsto x \cdot \partial f / \partial x \).

### 3.4. The sine-algebra and \( \psi DO_q \)

Here we identify \( q \)-analogs of \( \psi DO \) and sine-algebra, following M. Golenishcheva-Kutuzova (see [15]), and show that the invariant trace on \( \psi DO_q \) we have constructed above becomes the canonical invariant trace on the sine-algebra. We are grateful to M. Golenishcheva-Kutuzova for explaining to us this alternative approach to the trace description ([16]).

To define an associative product on elements of the sine-algebra, consider the “quantum torus”, i.e. the \( C^* \)-algebra \( A_h \) generated by two unitary operators \( U_1 \) and \( U_2 \), satisfying the relation \( U_2 U_1 = q U_1 U_2 \) (\( q = e^{i \theta} \)).

An arbitrary element of \( A_h \) can be written in the form of a formal series \( f = \sum_{n_1, n_2 \in \mathbb{Z}} f_{n_1, n_2} U_1^{n_1} U_2^{n_2} \). The Lie algebra structure on \( A_h \) is defined by

\[
[f, g] = f \cdot g - g \cdot f = \sum_{n, m \in \mathbb{Z}} f_{n_1, n_2} g_{(n_1 - n_2), (n_2 - n_1)} (q^{m_1 n_2} - q^{m_2 n_1}) U_1^{n_1 + m_1} U_2^{n_2 + m_2}.
\]

One can construct a two-dimensional central extension of this Lie algebra following the prescription of Section 2.1 above: the sine-algebra \( \hat{A}_h \) admits an ad-invariant trace \( \eta \left( \sum_{n_1, n_2} f_{n_1, n_2} U_1^{n_1} U_2^{n_2} \right) = f_{0,0} \). This trace allows one to associate a 2-cocycle with scalar values to every outer derivation of the algebra.

Let \( a = (a_1, a_2) \in \mathbb{C} \) and \( L_a \) be a derivation defined by \( L_{(a_1, a_2)}(U_1) = a_1 U_1, L_{(a_1, a_2)}(U_2) = a_2 U_2 \). Then the corresponding 2-cocycle is nothing but \( c(f, g) = \eta (L_a f \cdot g) \). Having chosen the basis in \( \hat{A}_h = A_h \oplus \mathbb{C} c \) in the form \( J_{k_1, k_2} = q^{\frac{k_1 k_2}{2}} U_1^{k_1} U_2^{k_2} \) we come to the commutation relations of the sine-algebra (2.4) with \( q = e^{4 \pi i / \lambda} \), see [15].

Consider now the homomorphism \( \phi : \sin_k \hookrightarrow \mathfrak{S}_q \) defined through \( \phi(U_1) = x, \phi(U_2) = D_q + \frac{1}{q-1} \).

**Proposition 3.5.** The \( \phi \)-pullback of the ad-invariant trace on \( \mathfrak{S}_q \) induces the ad-invariant trace \( \eta \) on the sine-algebra \( \sin_k \) (with \( q = e^{4 \pi i / \lambda} \)) up to a constant multiple.

**Proof.** Indeed,

\[
\text{Tr} \phi(U_1^{k} U_2^{l}) = \text{Tr} \left( x^k \left( D_q + \frac{1}{q-1} \right)^l \right)
= \int \text{res} \left( x^k \left( D_q + \frac{1}{q-1} \right)^l \frac{1}{(q-1)D_q + 1} \right)
= \frac{1}{q-1} \int \text{res} \left( x^k \left( D_q + \frac{1}{q-1} \right)^{l-1} \right)
= \frac{\delta_{k,0}}{q-1} \int x^k = \frac{1}{q-1} \delta_{k,0} \delta_{l,0}
\]

\[\square\]
Remark 3.2. The invariant inner product on both algebras is defined by the trace via
\[ \langle A, B \rangle = \text{Tr}(AB). \]

3.5. Bialgebra structure. We recall that the classical algebra \( \mathfrak{g} \) of pseudodifferential symbols can be equipped with a Lie bialgebra structure. Indeed, the algebra \( \mathfrak{g} \) as a linear space is a direct sum of two natural subalgebras: \( \mathfrak{g}_+ \) consisting of differential operators \( \sum_{j \geq 0} a_j D^j \), and \( \mathfrak{g}_- = \mathfrak{g}_{\text{Int}} \) consisting of integral symbols \( \sum_{j=-\infty}^{-1} a_j D^j \).

The triple of algebras \( (\mathfrak{g}, \mathfrak{g}_+, \mathfrak{g}_-) \) is a Manin triple (or, equivalently, \( \tilde{\mathfrak{g}}_{\text{Int}} = \tilde{\mathfrak{g}}_- \) is a Lie bialgebra) (see, e.g. [4]). This means that 1) the algebra \( \mathfrak{g} \) has an ad-invariant nondegenerate inner product (“Killing form”):
\[ \langle A, B \rangle = \int \text{res}(A \circ B) \]
for \( A, B \in \mathfrak{g} \), 2) as a linear space \( \mathfrak{g} = \mathfrak{g}_+ \oplus \mathfrak{g}_- \), and 3) both the subalgebras are isotropic with respect to this Killing form. The Lie group \( G_{\text{Int}} \) corresponding to the Lie bialgebra \( \tilde{\mathfrak{g}}_{\text{Int}} = \mathfrak{g}_- \) has a natural Lie-Poisson structure.

The Lie algebra \( s\mathfrak{g}_q = \{ A = \sum_{k=-\infty}^{n} u_k(x)T^k \mid \text{Tr } A = 0 \} \), where \( T = (q - 1)D_q + 1 \), is a sum of two isotropic subalgebras: of \( q \)-differential (\( \mathfrak{g}_q^+ = \{ \sum_{k=0}^{n} u_k(x)T^k \mid u_0 \in x\mathbb{C}[x] \} \)) and of \( q \)-integral operators (\( \mathfrak{g}_q^- = \{ \sum_{k=-\infty}^{0} u_k(x)T^k \mid u_0 \in x^{-1}\mathbb{C}[x^{-1}] \} \)) which are dual to each other with respect to the invariant inner product on \( s\mathfrak{g}_q \). Indeed, the commutation relation \( TX = qXT \) implies that \( (T^m x^n)_{m,n} \) and \( (x^{-n}T^{-m})_{m,n} \) are two bases dual to each other with respect to this form. Therefore, \( (s\mathfrak{g}_q, \mathfrak{g}_q^+, \mathfrak{g}_q^-) \) is also a Manin triple and \( s\mathfrak{g}_q \) is a Lie double.

Remark 3.3. A likewise Manin triple there exists for the extension \( \tilde{\mathfrak{g}} \) of \( \mathfrak{g} \) by a central and the corresponding cocentral terms (see Section 4). The corresponding Poisson structures on the nonextended and extended Lie groups \( G_{\text{Int}} \) are respectively the Benney and quadratic Gelfand-Dickey structures [23].

3.6. Quantum and classical \( W_\infty \)-algebras. The Lie algebras of \( W_\infty \)-type (having generators of all spins up to infinity) appeared recently in conformal field theory as the large \( n \) limit of Zamolodchikov’s quadratic \( W_n \)-algebras. Deep relations observed between these objects often look very natural and transparent after translation of them into the language of symbols. A “short dictionary” for some of these objects is just like this.

The (quantum) \( W_{1+\infty} \) algebra is isomorphic to the algebra \( \tilde{\mathfrak{g}}_{DO} \) which is the central extension of the algebra \( \mathfrak{g}_{DO} \) of differential operators on the circle [33].

The quantum \( W_\infty \) algebra is the truncated \( \tilde{\mathfrak{g}}_{DO} \) where zero order differential operators (i.e. functions) are discarded. Historically this algebra appeared to be spanned by “compositions” of the Virasoro (i.e. first order) generators. In this construction the space of functions does not appear. This explains the funny from mathematical viewpoint notation \( W_{1+\infty} \) for extension of \( W_\infty \) by functions.
Classical \( w_\infty \) algebra can be obtained from \( W_\infty \) by replacement of all commutators by Poisson brackets. In the language above this is nothing but the Poisson algebra of symbols of differential operators.

The symbols of differential operators are functions on a cylinder, the cotangent bundle \( T^*S^1 \) of the circle. These symbols are polynomial along the fiber \( p \). Generalization of \( DO \) to \( \psi DO \) invites one to consider symbols being Laurent series in \( p \) with coefficients periodic in \( q \) (and so defined on \( \{T^*S^1 \setminus S^1\} \)). Introducing an exponential coordinate along the fiber \( p = e^{i\cdot s} \) we come to a complex two-torus with coordinates \( s \) and \( q \). In these coordinates the outer derivation \( \{\log p, -\} \) becomes \( \{s, -\} \), the outer derivation of the Poisson algebra \( N \). Moreover, the coordinates \( s \) and \( q \) are symmetric in this representation.

Any symbol of a differential operator is a (Hamiltonian) function on \( T^*S^1 \) and defines a Hamiltonian vector field on this manifold. In such a way the group and the algebra of area preserving (or symplectic) diffeomorphisms on \( T^*S^1 \) appears in the context of \( w_\infty \). Moreover, any diffeomorphism of \( S^1 \) can be lifted to a symplectomorphism of \( T^*S^1 \). In physical terms this means that the group \( \text{Diff}(S^1) \) is a symmetry of \( W_\infty \) algebra (see e.g. [19]).

Finally, note that in the same way one can treat algebras of (pseudo)differential operators on a higher dimensional compact manifold \( M^n \). The algebra of Hamiltonian vector fields on \( T^*M^n \) appears as its classical limit, and the group \( \text{Diff}(M) \) as its symmetry (cf. [32]).

4. Lie algebra cocycles on \( \mathfrak{g} \) and \( \mathfrak{g}_q \)

4.1. Two-cocycles. Recall that the commutation rule

\[
[\partial^\alpha, u(x)] = \sum_{k \geq 1} \binom{\alpha}{k} u^{(k)}(x) \partial^{\alpha-k}
\]

makes sense not only for a positive integer \( \alpha \), but also for any complex values of \( \alpha \). Differentiating this identity in \( \alpha \) at \( \alpha = 0 \) and using undoubtful

\[
\frac{d}{d\alpha} \bigg|_{\alpha=0} \partial^\alpha = \log \partial \cdot \partial^{\alpha}|_{\alpha=0} = \log \partial
\]

we get commutation relation for a formal symbol \( \log \partial \) and a function \( u(x) \)

\[
[\log \partial, u(x)] = \sum_{k \geq 1} \frac{(-1)^{k+1}}{k} u^{(k)} \partial^{-k}
\]

(or, more generally \( [\log \partial, u(x)\partial^n] = \sum_{k \geq 1} \frac{(-1)^{k+1}}{k} u^{(k)} \partial^{-k-n} \)). Note that the result of the commutation lies in \( \psi DO \). In such a way the symbol \( \log \partial \) defined an outer derivation \( \xi_{\log \partial} \) of the ring \( \psi DO \), \( \xi_{\log \partial} \in H^1(\mathfrak{g}, \mathfrak{g}) \). Pairing the result of derivation with another symbol we get a complex-valued 2-cocycle \( c \in H^2(\mathfrak{g}, \mathbb{C}) \).
Theorem 4.1 ([26]). The following 2-cocycle

$$c(A, B) = \int \text{res}([\log \partial, A] \circ B) = \int \text{res} \left( \sum_{k \geq 1} \frac{(-1)^{k+1}}{k} A_x^{(k)} \partial^{-k} \circ B \right),$$

(4.1)

gives a nontrivial central extension $\hat{\mathfrak{g}}$ of the Lie algebra $\mathfrak{g}$. (Here $A$ and $B$ are arbitrary pseudodifferential symbols on $S^1$.) The restriction of this cocycle to $\mathfrak{g}_{DO}$ gives the nontrivial central extension of $\mathfrak{g}_{DO}$.

The restriction of this cocycle to the subalgebra of vector fields (considered as differential operators of the first order) is the Gelfand-Fuchs cocycle of the Virasoro algebra. This observation actually implies nontriviality of the cocycle on $\mathfrak{g}$ and $\mathfrak{g}_{DO}$. The “logarithmic” cocycle on the Lie algebra $\mathfrak{g}_{DO}$ can be also identified with the central charge of the $W_{1+\infty}$ algebra in conformal field theory ([1]).

Remark 4.1. Assume for a moment that log $\partial$ were an element of the algebra $\mathfrak{g}$. Then we could define not only the commutator $[\log \partial, A]$ but also a product $\log \partial \circ A$, and rewrite the cocycle $c(A, B) = \int \text{res}([\log \partial, A] \circ B)$ as $c(A, B) = \int \text{res}(\log \partial \circ [A, B])$. The last form means that the cocycle $c(A, B)$ is a 2-coboundary (and hence is trivial) because it is a linear function of the commutator: $c(A, B) = \langle \log \partial, [A, B] \rangle$. Recalling $\log \partial \notin \mathfrak{g}$, we get a heuristic proof of non-triviality of the cocycle.

Remark 4.2. Notice also that the Lie algebra $\mathfrak{g}_{DO}$ of differential operators on the circle has exactly one central extension ([8, 31, 40]), while the Lie algebra of pseudodifferential operators has exactly two independent central extensions (personal communication by B. L. Feigin). The formula for the second cocycle can be written in a similar to (4.1) form (see [23]):

$$c'(A, B) = \int \text{res}([\log x, A] \circ B)$$

for coefficients $a(x) \in \mathbb{C} [x, x^{-1}]$ or

$$c'(A, B) = \int \text{res}(x \circ [A, B])$$

for coefficients $a(x) \in C^\infty(S^1)$.

Here $x$ is a natural coordinate on the universal covering of $S^1$, considered as a multi-valued function on $S^1$. Note that here, as well as in the case of log $\partial$, the formal symbol $x$ is not an element of $\mathfrak{g}$ but a commutator $[x, A]$ is.

4.2. Derivations of the algebra of $q$-pseudodifferential operators. Analogously to the classical case, described in Section 4.1 we define here derivations of the deformed algebra $\mathfrak{g}_q$ by the symbols log $D_q$ and log $x$. 
4.2.1. The derivation \( \log D_q \). The classical case again gives us the recipe how to define an action of the operator \( \log D_q \) on \( q \)-pseudodifferential symbols \( A(x, D_q) \in \mathfrak{G}_q \). We consider the corresponding Lie group of \( q \)-symbols and its tangent structure.

**Proposition 4.2.** \( q \)-pseudodifferential symbols of the form \( u = D_q^a + \sum_{k \geq 1} u_k(x)D_q^{a-k} \) constitute an infinite dimensional Lie group \( G_q \) acting by automorphisms on the associative algebra \( \psi DO_q \), \( A \mapsto uAu^{-1}, u \in G_q \). The corresponding tangent Lie algebra is generated by integral \( q \)-operators and a symbol \( \log D_q \): 

\[
G_q = \{ \sum_{j=-\infty}^{-1} a_j(x)D_q^j + \lambda \log D_q \},
\]

where the commutation relations for \( \psi DO_q \) were defined above and the commutator of \( \log D_q \) with a symbol \( A = x^nD_q^p \) is

\[
[\log D_q, x^nD_q^p] \overset{\text{def}}{=} (\log q)nx^nD_q^p + \sum_{k \geq 1} \frac{(-1)^{k-1}}{k}(\tau^{-k}(D_q^kx^n))D_q^{p-k}
\]

(4.2)

\[
= (\log q)nx^nD_q^p + \sum_{k \geq 1} \frac{(-1)^{k-1}}{k}q^{-kn(n)}_q x^nD_q^{p-k}
\]

**Remark 4.3.** Analogously to the classical case the algebra of integral operators is closed under the commutations with \( \log D_q \). The main and crucial difference with the classics is the presence of the knot term \( (k = 0) \) in the formula for the \( \log D_q \). This shows that the group \( G_q \) of \( q \)-analogs is “solvable” and its properties are much different from the “unipotent” \( G_{\text{Int}} \) in the classical case.

**Proof of Proposition 4.2.** Indeed,

\[
\lim_{\epsilon \to 0} \frac{D_q^\epsilon(uD_q^p)D_q^{-\epsilon} - uD_q^p}{\epsilon} = \lim_{\epsilon \to 0} \frac{1}{\epsilon} \left\{ \sum_{k \geq 0} \left( \frac{\epsilon}{k} \right) (\tau^{-k}(D_q^k u))D_q^{p-k} - uD_q^p \right\}
\]

\[
= \lim_{\epsilon \to 0} \frac{\tau^\epsilon u - u}{\epsilon} D_q^p + \sum_{k \geq 1} \frac{(-1)^{k-1}}{k}(\tau^{-k}(D_q^kx^n))D_q^{p-k}.
\]

The formula for the action of \( \log D_q \) can be written also as the following version of the Leibnitz formula:

\[
[\log D_q, A] = (\log q)nx^nA + \sum_{k \geq 1} \frac{1}{k!} \left( \frac{d^{k-1}}{dD_q^{k-1}}D_q^{-1} \right) \ast (D_q^k A)
\]

(4.3)

where \( A = x^nD_q \). Note that the two logarithmic terms do not cancel in (4.3) as it was in the classical case (see [K-K]), but generate the first right hand side term.

**Proposition 4.3.** The action of \( \log D_q \) is a derivation of the associative algebra \( \psi DO_q \): 

\[
[\log D_q, A \circ B] = A \circ [\log D_q, B] + [\log D_q, A] \circ B.
\]

**Proof.** This immediately follows from the fact that \( \log D_q \) is a tangent vector to the Lie group \( G_q \).
The inner product allows to define a 2-cocycle on the corresponding Lie algebra:

\[ c_D(A, B) = \int \text{res}([\log D_q, A]BE). \]

**Proposition 4.4.** The 2-cochain \( c_D(A, B) \) is antisymmetric and satisfies the cyclic cocycle identity.

**Proof.** First note that \( \int \text{res}([\log D_q, A]) = 0 \) for any \( A \in \mathfrak{G}_q \) by (4.2). Indeed, \( \int nx^n = 0 \) for all \( n \in \mathbb{Z} \) and \( \tau^{-k}(D_q f) = 0 \) for all \( k > 0 \). This implies

\[ 0 = \int \text{res}([\log D_q, ABE]) = \int \text{res}([\log D_q, A]BE) + \int \text{res}(A[\log D_q, B]E) = c_D(A, B) + c_D(B, A) \]

because \([\log D_q, E] = 0\) and by Theorem 3.3. The cyclic cocycle property follows from antisymmetry identity and Proposition 4.3. □

**Remark 4.4.** The restriction of this Lie 2-cocycle to the Lie algebra of \( q \)-differential operators (containing polynomials in \( \partial_q \) only) gives a non-trivial cocycle, cohomologous to the \( q \)-deformation of the Kac-Peterson cocycle [20] constructed by Kassel [22].

**Proposition 4.5.** In the Kac-Radul construction (see Section 3.3.4), if one chooses

\[ \text{Tr}_D \left( \sum_{p=-\infty}^{N} a_p x^p \right) = \sum_{p=0}^{N} a_p \frac{(-1)^p}{(q-1)^{p+1}} \left\{ \log q + \sum_{k=1}^{p} \frac{(1 - q)^k}{k} \right\} \]

as the trace on \( A \), then the 2-cocycle \( \psi_{\sigma, \text{Tr}} \) induces on \( \mathfrak{G}_q \) the same cocycle \( c_D \) described above.

**Proof.** Compute explicitly the cocycle \( c_D \):

\[ c_D(x^m \sigma^m(D_q^a), x^n D_q^b) = \int \text{res}(x^n D_q^b \circ [\log D_q, x^m] \sigma^m(D_q^a \circ E)) \]

\[ = \delta_{n+m,0} \text{res} \left\{ \sigma^m(D_q)^{a+b} \left( m \log q + \sum_{k>0} \frac{(-1)^{k-1}}{k} q^{-km}(m)^k D_q^{-k} \right) \right\} . \]

On the other hand

\[ \psi(x^m \sigma^m(\xi^a), x^n \xi^b) = \delta_{n+m,0} \text{Tr}_D(1 + \sigma + \ldots + \sigma^{m-1}) \xi^{a+b} \]

for \( m > 0 \). This gives an equation to determine \( \text{Tr}_D \)

\[ \text{Tr}_D(1 + \sigma + \ldots + \sigma^{m-1}) \xi^c = \text{res} \left\{ \sigma^m(\xi^c) \left( m \log q + \log(1 + q^{-m}(m)^\xi^{-1}) \right) \right\}. \]

(4.4)

Put \( m = 1 \) and define \( \text{Tr}_D \) via the right hand side

\[ \text{Tr}_D \xi^c = \text{res} \left\{ (q \xi + 1)^c \left( \log q + \sum_{k>0} \frac{(-1)^{k-1}}{k} q^{-k}(\xi^{-1}) \right) \right\} \]
in particular, $\text{Tr}_D \xi^c = 0$ if $c < 0$.

We want to prove (4.4) for $m > 1$. Summing up these equations with weights $\sum_{c=0}^b \binom{b}{c} (q - 1)^c$ we get an equivalent form

$$\text{Tr}_D (1 + \sigma + \cdots + \sigma^{m-1})(1 + (q-1)D)^b = \text{res}\left\{(1 + (q-1)\sigma^m(\xi))^b \log(q^m + (m)q\xi^{-1})E\right\}.$$  

Since $\sigma(1 + (q-1)\xi) = q(1 + (q-1)\xi)$ this is the same as

$$(m)_q b \text{Tr}_D (1 + (q-1)\xi)^b = q^b \text{res}\{(1 + (q-1)\xi)^b \log(q^m + (m)q\xi^{-1})\}.$$  

The definition of $\text{Tr}_D$ gives

$$\text{Tr}_D (1 + (q-1)\xi)^b = \text{res}\{(1 + (q-1)(q\xi + 1))^b \log(q + \xi^{-1})E\} = q^b \text{res}\{(1 + (q-1)\xi)^{b-1} \log(q + \xi^{-1})\}.$$  

So the identity to prove is

$$(m)_q b \text{res}\{(1 + (q-1)\xi)^{b-1} \log(q + \xi^{-1})\} = \text{res}\{(1 + (q-1)\xi)^{b-1} \log(q^m + (m)q\xi^{-1})\}$$

for $b \in \mathbb{Z}_{>0}$. Computing the residue by differentiation with respect to $q^{-m}$ we see that the both sides are equal to $b^{-1}(q^{-mb} - 1)(1-q)^{-1}$. This gives a simple expression for $\text{Tr}_D$

$$\text{Tr}_D (1 + (q-1)\xi)^b = \frac{(b)_q}{b} \quad \text{for } b > 0,$$

whence

$$\text{Tr}_D \xi^p = (-1)^p \frac{\log q}{(q - 1)^{p+1}} + \frac{1}{(q - 1)^p} \sum_{k=1}^p (-1)^{p-k} \binom{p}{k} \frac{q^k}{k}$$

$$= \frac{(-1)^p}{(q - 1)^{p+1}} \left(\log q + \sum_{k=1}^p (-1)^k \binom{p}{k} \left(\frac{q^k}{k} - \frac{1}{k}\right)\right) \quad (4.5)$$

for $p \in \mathbb{Z}_{>0}$. Denote $f(q) = \sum_{k=1}^p (-1)^k \binom{p}{k} \frac{q^k}{k}$. Since $q f'(q) = (1-q)^p - 1$ we can write $f'(q) = -\sum_{n=0}^{p-1} (1-q)^n$. Plugging $f(q) - f(1) = \sum_{n=1}^p \frac{(1-q)^n}{n}$ to (4.5) we obtain

$$\text{Tr}_D \xi^p = \frac{(-1)^p}{(q - 1)^{p+1}} \left(\log q + \sum_{k=1}^p \frac{(1-q)^k}{k}\right).$$

\[\square\]

Remark 4.5. For $q$ close to 1 and $p \geq 0$ this trace can be presented as

$$\text{Tr}_D \xi^p = \sum_{m=0}^\infty \frac{(1-q)^m}{m + p + 1}.$$  

In particular, when $q \to 1$ the trace $\text{Tr}_D$ is non-singular and $\lim_{q \to 1} \text{Tr}_D \xi^p = \frac{1}{p+1}$.  

4.2.2. The derivation $\log x$. Analogously, one can define a twisted derivation $l_x$:

$$l_x(fD_q^a) = a f(x) D_q^{a-1} = \frac{d}{dD_q}(fD_q^a)$$

for any $A \in \psi DO_q$.

**Proposition 4.6.** The map $l_x$ is a twisted derivation of the associative algebra $\psi DO_q$:

$$l_x(AB) = l_x(A) \tau(B) + A \cdot l_x(B)$$

**Proof.** Calculation. □

**Corollary 4.7.** The map $[\log x, -]$ determined by

$$[\log x, A] = -l_x(A)E^{-1} = -l_x(A)((q - 1)D_q + 1)$$

is a derivation of the associative algebra $\psi DO_q$.

**Proof.** Indeed,

$$[\log x, AB] = -l_x(AB)E^{-1}$$

$$= -l_x(A)E^{-1}BEE^{-1} - A \cdot l_x(B)E^{-1}$$

$$= [\log x, A]B + A[\log x, B].$$

□

**Proposition 4.8.** The bilinear form

$$c_x(A, B) = \int \text{res}(A[\log x, B]E) = -\int \text{res}(A l_x(B))$$

is a skew-symmetric cyclic cocycle.

**Proof.** Indeed,

$$0 = \int \text{res}(l_x(AB)) = \int \text{res}(l_x(A)\tau(B)) + \int \text{res}(A l_x(B))$$

$$= \int \text{res}(B l_x(A)) + \int \text{res}(A l_x(B))$$

implies that $c_x$ is skew-symmetric. Also,

$$c_x(A, BC) = -\int \text{res}(AB l_x(C)) - \int \text{res}(A l_x(B)\tau(C))$$

$$= c_x(AB, C) + c_x(CA, B)$$

is the cyclic cocycle property. □

When restricted to differential operators, the cocycle $c_x$ vanishes.

**Remark 4.6.** In the case of the algebra $C^\infty(S^1)$ we can introduce a coordinate $\theta$ on the universal covering $\mathbb{R}^1$ of the circle $S^1$ so that $x = e^{i\theta}$. This is not a function from $C^\infty(S^1)$, but for any $A \in \mathfrak{g}_q$ we can form a commutator $[\theta, A] \in \mathfrak{g}_q$. 
Now we find the commutator of the two derivations.

**Proposition 4.9.** For any \( A \in \mathfrak{g}_q \)

\[
[\log D_q, [\log x, A]] - [\log x, [\log D_q, A]] = [D_q^{-1}, A].
\]

**Proof.** Assume \( A = x^n D_q^a \). The left hand side is

\[
[\log D_q, [\log x, x^n D_q^a]] - [\log x, [\log D_q, x^n D_q^a]] =
\]

\[
= -a \left\{ (\log q)nx^n + \sum_{k \geq 1} \frac{(-1)^{k-1}}{k} q^{-kn}(n)_q^k x^n D_q^{-k} \right\} (D_q^{a-1} + (q - 1)D_q^a)
\]

\[
+ a(\log q)nx^n(D_q^{a-1} + (q - 1)D_q^a)
\]

\[
+ \sum_{k \geq 1} \frac{(-1)^{k-1}}{k} q^{-kn}(n)_q^k(a - k)x^n(D_q^{a-k-1} + (q - 1)D_q^{-k})
\]

\[
= x^n(D_q^{a-1} + (q - 1)D_q^a)\sum_{k \geq 1}(-1)^k q^{-kn}(n)_q^k D_q^{-k}
\]

\[
= -(n)_q x^n(D_q^{a-1} + (q - 1)D_q^a)(q^n D_q + (n)_q)^{-1}.
\]

The right hand side is

\[
[D_q^{-1}, x^n D_q^a] = x^n(q^n D_q + (n)_q)^{-1}D_q^{-a} - x^n D_q^{-a-1}
\]

\[
= x^n(q^n D_q + (n)_q)^{-1}D_q^{-a-1}((1 - q^n)D_q - (n)_q)
\]

\[
= (n)_q x^n(q^n D_q + (n)_q)^{-1}D_q^{-a-1}((1 - q)D_q - 1)
\]

which coincides with the expression above. \( \square \)

**Corollary 4.10.** One can equip the vector space \( \mathfrak{g}_q = \mathfrak{g}_q \oplus \mathbb{C} \log D_q \oplus \mathbb{C} \log x \) with a Lie algebra structure such that \( \mathfrak{g}_q \) is an ideal and

\[
[\log D_q, \log x] = D_q^{-1}.
\]

There exists an exact sequence of Lie algebras \( 0 \to \mathfrak{g}_q \to \mathfrak{g}_q \to \mathbb{C}^2 \to 0 \).

4.3. 3-cocycles on \( \mathfrak{g} \) and \( \mathfrak{g}_q \). Since the Lie algebra \( \mathfrak{g}_q \) has an invariant form it inherits also the standard 3-cocycle \( c_0^3(L, M, N) = \int \text{res}([L, M]NE) \) defined for \( q \neq 1, 0 \). For \( q = 1 \) there is a cocycle \( c_0^3(L, M, N) = \int \text{res}([L, M]N) \) on \( \mathfrak{g} \).

**Proposition 4.11.** The cocycle \( c_0^3 \) is non-singular as \( q \to 1 \) and, moreover,

\[
\lim_{q \to 1} c_0^3 = c_0^3.
\]

**Proof.** It suffices to check this for \( L = x^l D_q^a \), \( M = x^m D_q^b \), \( N = D_q^c \circ x^n \). Change for \( q \neq 1 \) the variable \( D_q \) to \( T = (q - 1)D_q + 1 \), then \( \psi D_q \) consists of formal power series.
\[ \sum_{k=-\infty}^{N} u_k(x) T^k. \]

Define \( \text{res}_T : \psi DO_q \to F \), \( \text{res}_T(\sum_{k=-\infty}^{N} u_k(x) T^k) = u_{-1}(x) \), then \( \text{res}_T = (q-1) \text{res} \). Substituting \( D_q = T(1-T^{-1})/(q-1) \) we find

\[
\int \text{res}([L, M] NE) = \frac{1}{q-1} \int \text{res}_T([L, M] NT^{-1})
\]

\[
= \frac{1}{(q-1)^{a+b+c+1}} \int \text{res}_T \{ x^n [x^T^{a} (1-T^{-1})^a, x^m T^b (1-T^{-1})^b] T^c (1-T^{-1})^c T^{-1} \}
\]

\[
= \frac{1}{(q-1)^{a+b+c+1}} \int \text{res}_T \{ x^{l+m+n} ((q^m T)^{a} (1-q^{-m} T^{-1})^{a} T^b (1-T^{-1})^b)
\]

\[
- (q^l T)^{b} (1-q^{-l} T^{-1})^{a} T^c (1-T^{-1})^c \}
\]

\[
= \frac{\delta_{l+m+n,0}}{(q-1)^{a+b+c+1}} \text{res}_T \{ q^{ma T^{a+b+c-1}} \sum_{k \geq 0} (-1)^{k} \binom{a}{k} q^{-mk T^{-k}} \sum_{p \geq 0} (-1)^{p} \binom{b+c}{p} T^{-p}
\]

\[
- q^{tb} T^{a+b+c+1} \sum_{k \geq 0} (-1)^{k} \binom{b}{k} q^{-lk T^{-k}} \sum_{p \geq 0} (-1)^{p} \binom{a+c}{p} T^{-p} \}
\]

\[
= (-1)^{a+b+c} \frac{\delta_{l+m+n,0}}{(q-1)^{a+b+c+1}} \sum_{k+p=a+b+c, k,p \geq 0} \binom{a}{k} \binom{b+c}{p} q^{m(a-k)}
\]

\[
- \sum_{k+p=a+b+c, k,p \geq 0} \binom{b}{k} \binom{a+c}{p} q^{l(b-k)} \}
\]

For \( s \in \mathbb{Z}_{\geq 0}, a \in \mathbb{Z} \) introduce the function

\[
f_a(z) = \sum_{k+p=a+b+c} \binom{a}{k} \binom{s-a}{p} z^{a-k}.
\]

It is the coefficient at \( t^a \) in the decomposition

\[
(z + t)^a (1+t)^{s-a} = \sum_{m \geq 0} t^m \sum_{k+p=a} \binom{a}{k} \binom{s-a}{p} z^{a-k}.
\]

Differentiating the last relation with respect to \( z \) we find

\[
f_a(1) = 1,
\]

\[
\frac{d^n}{dz^n} f_a(z) |_{z=1} = n! \binom{a}{n} \binom{s-n}{s},
\]

in particular, \( f_a^{(n)}(1) = 0 \) for \( 1 \leq n \leq s \). Therefore, \( f_a(z) = 1 + (z-1)^{s+1} g_a(z) \) for some Laurent polynomial \( g_a(z) \), such that \( g_a(1) = (-1)^s \binom{a}{s+1} \).
Assuming \( s = a + b + c \geq 0 \) and plugging \( f_a(q^m) - f_b(q^l) \) to \( c_0^q(L, M, N) \) we see that the limit exists and

\[
\lim_{q \to 1} \int \res([L, M] NE) = \delta_{l+m+n,0} \left\{ \binom{a}{a + b + c + 1} m^{a+b+c+1} - \binom{b}{a + b + c + 1} l^{a+b+c+1} \right\}.
\]

Now we calculate the value of \( c_0^q \) on \( L = x^l D^a, M = x^m D^b, N = D^c \circ x^n \) when \( q = 1 \):

\[
\int \res([L, M] N) = \int \res([x^l D^a, x^m D^b] D^c x^n)
\]

\[
= \int \res\{ x^{l+m+n} ((D + m)^a D^b - (D + l)^b D^a) D^c \}
\]

\[
= \delta_{l+m+n,0} \res\{ \sum_{k \geq 0} \binom{a}{k} m^k D^{a-k+b+c} - \sum_{k \geq 0} \binom{b}{k} l^k D^{b-k+a+c} \}
\]

\[
= \delta_{l+m+n,0} \left\{ \binom{a}{a + b + c + 1} m^{a+b+c+1} - \binom{b}{a + b + c + 1} l^{a+b+c+1} \right\}
\]

which coincides with the previous limit. \( \square \)

**Remark 4.7.** If \( a, b, a + c, b + c \geq 0 \), then \( c_0^q(x^l D^a, x^m D^b, D^c \circ x^n) = 0 \). Indeed, as follows from (4.6) \( f_a(z) = 1 \) for \( 0 \leq a \leq s \). In particular, the restriction of \( c_0^q \) to the subalgebra \( DO_q \) vanishes identically.

Two outer derivations \( \xi = \ad \log D_q \) and \( \eta = \ad \log x \in H^1(\mathfrak{g}_q, \mathfrak{g}_q) \) produce not only two complex valued two-cocycles. They also induce a 2-cocycle \( \xi \) from (4.6) \( f_a \) (Z, \( \mathfrak{g}_q, \mathfrak{g}_q) \): it can be considered as the cup product of those two classes.

**Remark 4.8.** In contrast to the classical case of Poisson algebra, the cocycle \( f \) is non-trivial, at least for \( q = 1 \), as the following argument shows. Since \( \mathfrak{g} \) is isomorphic to its own dual as a representation of itself, one has \( f \in H^2(\mathfrak{g}, \mathfrak{g}^*) \) and one can check that its restriction to vector fields \( \mathfrak{A}(S^1) \) is non-trivial: one has \( I^*(f) \) is \( H^2(\mathfrak{A}(S^1), \mathfrak{g}^*) \) but as an \( \mathfrak{A}(S^1) \)-module \( \mathfrak{g}^* \) splits into a direct sum \( \mathfrak{g}^* = \bigoplus_{n \in \mathbb{Z}} \mathcal{F}_n \), where \( \mathcal{F}_n \) is the space of \( n \)-densities. Then \( I^*(f) \in H^2(\mathfrak{A}(S^1), \mathcal{F}_2) \) and one computes easily

\[
I^*(f) (a \partial_x, b \partial_x) = (a''b' - a'b'') dx^2.
\]

The non-triviality of the cohomology class of this cocycle can either be proved directly using Fuchs’ computations [9] for non trivial representations of \( \mathfrak{A}(S^1) \) or either remark that \( \mathcal{F}_2 = \mathfrak{A}(S^1) \) and this class \( I^*(f) \) then induces the Godbillon-Vey generator in \( H^3(\mathfrak{A}(S^1), \mathbb{R}) \).

The cocycle \( f \) will give rise to a non trivial complex valued three-cocycle on \( \mathfrak{g}_q \) via the map \( \theta \).
Theorem 4.12. The complex valued cochain on $G_q$ defined by
\[
c_{GV}(L, M, N) = \text{Alt}_{L,M,N} \int \text{res}(\xi(M)N\eta(L) - M\xi(N)\eta(L) - LMND_{q-1}E)
\]
\[
= \text{Alt}_{L,M,N} \int \text{res}(M\xi(N)l_x(L) - \xi(M)Nl_x(L) - LMND_{q-1} + (q-1)LMNE)
\]
is a three-cocycle, defined for $q \neq 0, 1$ and having a limit as $q \to 1$ which is a non trivial cocycle on $G$
\[
c_{GV}(L, M, N) = \text{Alt}_{L,M,N} \int \text{res}(\xi(M)N\eta(L) - M\xi(N)\eta(L) - LMND^{-1}).
\]

Proof. Consider the 3-cochain
\[
\theta(f)(L, M, N) = \text{Alt}_{L,M,N} \text{Tr}(\eta(L)\xi(M)N - \xi(L)\eta(M)N)
\]
(sum over 6 permutations). Its coboundary is given by the Lemma 2.3
\[
d\theta(f)(L, M, N, P) = \text{Alt}_{L,M,N,P} \text{Tr}(\eta(L)\xi(M)[N, P] - \xi(L)\eta(M)[N, P])
\]
(12 shuffles)
\[
= \text{Alt}_{L,M,N,P} \text{Tr}(\eta(L)\xi(M)NP - \xi(L)\eta(M)NP)
\]
(24 permutations)
\[
\overset{(1)}{=} \frac{1}{2} \text{Alt}_{L,M,N,P} \text{Tr}([\eta, \xi](L)MNP)
\]
(24 permutations)
\[
= -\frac{1}{2} \text{Alt}_{L,M,N,P} \text{Tr}([D_q^{-1}, L]MNP)
\]
(24 permutations)
\[
= - \text{Alt}_{L,M,N,P} \text{Tr}(D_q^{-1}LMNP)
\]
(24 permutations)
\[
\overset{(2)}{=} -da(L, M, N, P)
\]
where
\[
a(L, M, N) = \text{Alt}_{L,M,N} \text{Tr}(D_q^{-1}LMN) \quad \text{(sum over 6 permutations)}.
\]

Here we used Proposition 4.9 and equation (1) is deduced by “integration by parts”, that is from the property $\text{Tr}(\xi(A)) = 0, \text{Tr}(\eta(A)) = 0$ for any $A \in G_q$. Equation (2) illustrate the difference between odd and even cochains.

This implies that
\[
c_{GV}(L, M, N) = \theta(f)(L, M, N) + a(L, M, N)
\]
is a 3-cocycle well defined for $q \neq 0, 1$. The formula
\[
c_{GV}(L, M, N) = \text{Alt}_{L,M,N} \int \text{res}(M\xi(N)l_x(L) - \xi(M)Nl_x(L) - LMND_{q-1}((q-1)D_q + 1)^{-1})
\]
shows that the cocycle has a limit as $q \to 1$ iff its last summand
\[
\text{Alt}_{L,M,N} \int \text{res}(LMND_{q-1}((q-1)D_q + 1)^{-1})
\]
has a limit. Since
\[ \frac{1}{D_q((q-1)D_q+1)} = \frac{1}{D_q} - \frac{q-1}{(q-1)D_q+1} \] (4.7)
we have
\[ \text{Alt}_{L,M,N} \int \text{res}(LMND_q^{-1}E) = \text{Alt}_{L,M,N} \int \text{res}(LMND_q^{-1}) - (q-1) \text{Alt}_{L,M,N} \int \text{res}(LMNE) \]
\[ = \text{Alt}_{L,M,N} \int \text{res}(LMND_q^{-1}) - 3(q-1)c_0^q(L, M, N). \]

We know that \( c_0^q \) is not singular when \( q \) tends to 1 by Proposition 4.11. Therefore,
\[ c_{GV}(L, M, N) = \]
\[ = \text{Alt}_{L,M,N} \int \text{res}(M\xi(N)l_x(L) - \xi(M)Nl_x(L) - LMND_q^{-1}) + 3(q-1)c_0^q(L, M, N) \]

is not singular either and
\[ \lim_{q \to 1} c_{GV}(L, M, N) = \text{Alt}_{L,M,N} \int \text{res}(M\xi(N)l_x(L) - \xi(M)Nl_x(L) - LMND_q^{-1}). \]

The last cocycle on \( \mathfrak{g} \) can be obtained also via the same reasoning as for \( q \neq 1 \).

Non-triviality of the cocycle for \( q = 1 \) follows from explicit calculation. Computing it on the first order difference operators \( L = x^lD_q, M = x^mD_q, N = x^nD_q \) we get
\[ c_{GV}(x^lD_q, x^mD_q, x^nD_q) = \frac{1}{2} \delta_{l+m+n,0} \text{Alt}_{l,m,n} q^{-n}(m)_q(n)_q^2. \]

As \( q \to 1 \) the operator \( D_q \) tends to \( D = x\partial_x \) and \( L, M, N \) tend to vector fields on \( S^1 \).
Therefore, the restriction of this cocycle at \( q = 1 \) to the algebra of vector fields \( \mathfrak{g}(S^1) \) is
\[ c_{GV}(fD, gD, hD) = \frac{1}{2} \int_{S^1} \begin{vmatrix} f & Df & D^2f \\ g & Dg & D^2g \\ h & Dh & D^2h \end{vmatrix} dx \]
which is the generator of the \( H^3(\mathfrak{g}(S^1), \mathbb{C}) \) found in [11]. \( \square \)

The Godbillon-Vey form of this cocycle after restriction to vector fields suggests the name “quantum” Godbillon-Vey 3-cocycle for \( c_{GV}(L, M, N) \).

**Proposition 4.13.** The cocycle \( c_{GV} \) extends to a 3-cocycle on the Lie algebra \( \mathfrak{g}_q \oplus \mathbb{R}\log D_q \) by the formula
\[ c_{GV}(\log D_q, L, M) = 3 \int \text{res}\{(L[\log D_q, M]D_q^{-1} + LD_q^{-1}[\log D_q, M])E\} \]
for \( L, M \in \psi DO_q, q \neq 0, 1 \). When \( q \to 1 \) the cocycle is not singular and
\[ \lim_{q \to 1} c_{GV}(\log D_q, L, M) = 3 \int \text{res}\{L[\log D, M]D^{-1} + LD^{-1}[\log D, M]\}. \]
Proof. Since $\text{Tr}(D^\alpha_q LD_q^{-\alpha}) = \text{Tr} L$ for $\alpha \in \mathbb{R}$,
\[
c_{GV}([\log D_q, L], M, N) + c_{GV}(L, [\log D_q, M], N) + c_{GV}(L, M, [\log D_q, N]) =
\]
\[
= \frac{d}{d\alpha}c_{GV}(D^\alpha_q LD_q^{-\alpha}, D^\alpha_q MD_q^{-\alpha}, D^\alpha_q ND_q^{-\alpha})|_{\alpha=0}
\]
\[
= \text{Alt}_{L,M,N} \text{Tr}((\xi(L)N - M\xi(N))[\eta, \xi](L))
\]
\[
= \text{Alt}_{L,M,N} \text{Tr}(\xi(L)D_q^{-1}M|N - [D_q^{-1}, L]\xi(M)N)
\]
\[
= da_2(L, M, N)
\]
the cochain $a_2$ being defined as
\[
a_2(L, M) = 3 \text{Tr}(\xi(L)D_q^{-1}M + D_q^{-1}\xi(L)M)
\]
(we used the obvious $\xi(D_q^{-1}) = 0$). Therefore, extending $c_{GV}$ to a cochain on $\mathfrak{g}_q \oplus \mathbb{R}\log D_q$ by $c_{GV}(\log D_q, L, M) = -a_2(L, M)$ we obtain a cocycle.

Using again (4.7) we transform the cocycle to
\[
c_{GV}(\log D_q, L, M) = 3 \int \text{res}\{(L[\log D_q, M] + [\log D_q, M]L)(D_q^{-1} - (q-1)E)\}
\]
\[
= 3 \int \text{res}\{(L[\log D_q, M] + [\log D_q, M]L)D_q^{-1}\} - 6(q-1)c_D(M, L).
\]
This is non-singular because $c_D$ is not singular by Proposition 4.5, whence the formula for limit follows. □

4.4. Higher cocycles on $\mathfrak{g}$ and $\mathfrak{g}_q$. Gelfand and Mathieu constructed a family of Lie algebra cocycles in the following situation. Let $A$ be an associative algebra and $\mathfrak{h}$ be an abelian Lie subalgebra of $\text{Der} A$. Let $\text{Tr} : A \to \mathbb{C}$ be $\mathfrak{h}$-invariant trace. Then there are some cocycles from $Z^k((A, [\cdot, \cdot]), \mathbb{C})$ associated with these data (see [12]). We consider similar case of 2-dimensional subspace $\mathfrak{h} \subset \text{Der} \mathfrak{A}$ such that its image in $\text{Out} A = \text{Der} A/\text{Inn} A$ is an abelian Lie subalgebra. That is, we consider two derivations $\xi, \eta$ such that their commutator is inner. The results are formulated in the particular case $A = \psi DO_q$, $\xi = \text{ad} \log D_q$, $\eta = \text{ad} \log x$.

Proposition 4.14. For any odd $n \geq 1$ there is a cocycle in $Z^n(\mathfrak{g}_q, \mathbb{C})$
\[
c^{(n)}(X_1, \ldots, X_n) = \text{Alt}_{X_1, \ldots, X_n} \text{Tr}(X_1 \cdots X_n).
\]
For $n \geq 3$ it is continuous at $q = 1$:
\[
\lim_{q \to 1} c^{(n)}(X_1, \ldots, X_n) = c^{(n)}|_{q=1}(\lim_{q \to 1} X_1, \ldots, \lim_{q \to 1} X_n).
\]
For $n \geq 3$ (and for $n = 1$ if $q = 1$) its restriction to $DO_q$ vanishes.

Proof. The first claim is standard (cf. [12]). The other claims follow from a particular case $n = 3$, considered in Proposition 4.11 and Remark 4.7. □
Proposition 4.15. For any even \( n \geq 2 \) there are cocycles in \( Z^n(\mathfrak{g}, \mathbb{C}) \)

\[
c_D^{(n)}(X_1, \ldots, X_n) = \text{Alt}_{X_1, \ldots, X_n} \text{Tr}([\log D, X_1]X_2 \cdots X_n),
\]

\[
c_x^{(n)}(X_1, \ldots, X_n) = \text{Alt}_{X_1, \ldots, X_n} \text{Tr}([\log x, X_1]X_2 \cdots X_n).
\]

They are continuous at \( q = 1 \):

\[
\lim_{q \to 1} c_D^{(n)} = c_D^{(n)}|_{q=1}, \quad \lim_{q \to 1} c_x^{(n)} = c_x^{(n)}|_{q=1}.
\]

The restriction of \( c_x^{(n)} \) to \( DO_q \) vanishes.

Proof. The first claim follows from results of Gelfand and Mathieu [12]. Continuity of \( c_D \) follows from the particular case \( n = 2 \) (see Proposition 4.5 and Remark 4.5). The claims about \( c_x \) follow from the presentation

\[
c_x^{(n)}(X_1, \ldots, X_n) = - \text{Alt}_{X_1, \ldots, X_n} \int \text{res}(X_2 \cdots X_n l_x(X_1))
\]

valid for any \( q \). \( \square \)

Theorem 4.16. For any odd \( n \geq 3 \) there is a cocycle in \( Z^n(\mathfrak{g}, \mathbb{C}) \)

\[
c_{x,D}^{(n)}(X_1, \ldots, X_n) = \text{Alt}_{X_1, \ldots, X_n} \text{Tr} \left( \sum_{i=1}^{n-1} \xi(X_1)X_2 \cdots \eta(X_{2i}) \cdots X_n \right.
\]

\[
- \left. \xi(X_1)X_2 \cdots X_{n-1} \eta(X_n) - D_q^{-1}X_1X_2 \cdots X_n \right).
\]

It is continuous at \( q = 1 \):

\[
\lim_{q \to 1} c_{x,D}^{(n)}(X_1, \ldots, X_n) = c_{x,D}^{(n)}|_{q=1} \left( \lim_{q \to 1} X_1, \ldots, \lim_{q \to 1} X_n \right).
\]

Proof. Consider the \( n \)-cochain

\[
b_n(X_1, \ldots, X_n) = \text{Alt}_{X_1, \ldots, X_n} \text{Tr} \left( \sum_{i=1}^{n-1} \xi(X_1)X_2 \cdots \eta(X_{2i}) \cdots X_n - \xi(X_1)X_2 \cdots X_{n-1} \eta(X_n) \right)
\]

which can be written as

\[
b_n = \text{Tr} \left( \sum_{i=1}^{n-1} \xi \cup m^{2(i-1)} \cup \eta \cup m^{n-2i} - \xi \cup m^{n-2} \cup \eta \right),
\]

where \( m^k(Y_1, \ldots, Y_k) = \text{Alt}_{Y_1, \ldots, Y_k} Y_1 \cdots Y_k \) and \( a \cup b \overset{\text{def}}{=} \mu(a \otimes b) \), \( \mu \) being the multiplication. Since \( m^k = m^1 \cup m^1 \cup \cdots \cup m^1 \) and \( dm^1 = m^2 \), we have \( dm^k = m^{k+1} \) for odd \( k \),
and $dm^k = 0$ for even $k$. Therefore,

$$db_n = \text{Tr} \left( \sum_{i=1}^{\frac{n-1}{2}} \xi \cup m^{2(i-1)} \cup \eta \cup m^{n+1-2i} + \xi \cup m^{n-1} \cup \eta \right)$$

$$= \text{Tr} \sum_{i=1}^{\frac{n+1}{2}} \xi \cup m^{2(i-1)} \cup \eta \cup m^{n+1-2i}$$

$$= \frac{1}{2} \text{Tr}(\xi, \eta \cup m^n)$$

due to the following identity

$$\frac{1}{2} \text{Alt} \text{Tr}((\xi \eta)(X_1)X_2 \cdots X_{n+1} - (\eta \xi)(X_1)X_2 \cdots X_{n+1}) =$$

$$= \frac{1}{2} \text{Alt} \text{Tr}(-\sum_{i=2}^{n+1} \eta(X_1)X_2 \cdots \xi(X_i) \cdots X_{n+1} + \sum_{j=2}^{n+1} \xi(X_1)X_2 \cdots \eta(X_j) \cdots X_{n+1})$$

$$= \frac{1}{2} \text{Alt} \text{Tr}(-\sum_{i=2}^{n+1} (-1)^{i-1} \xi(X_1)X_2 \cdots \eta(X_{n-i+3}) \cdots X_{n+1}$$

$$+ \sum_{j=2}^{n+1} \xi(X_1)X_2 \cdots \eta(X_j) \cdots X_{n+1})$$

$$= \frac{1}{2} \text{Alt} \text{Tr} \sum_{j=2}^{n+1} [(-1)^{n+3-j} + 1]\xi(X_1)X_2 \cdots \eta(X_j) \cdots X_{n+1}$$

$$= \text{Alt} \text{Tr} \sum_{i=1}^{\frac{n+1}{2}} \xi(X_1)X_2 \cdots \eta(X_{2i}) \cdots X_{n+1}.$$ 

Hence,

$$db_n = \frac{1}{2} \text{Tr}(\text{ad}_{D_q^{-1}} \cup m^n)$$

and we get

$$db_n(X_1, \ldots, X_{n+1}) = \frac{1}{2} \text{Alt}_{X_1, \ldots, X_{n+1}} \text{Tr}(D_q^{-1}X_1X_2 \cdots X_{n+1} - X_1D_q^{-1}X_2 \cdots X_{n+1})$$

$$= \text{Alt}_{X_1, \ldots, X_{n+1}} \text{Tr}(D_q^{-1}X_1X_2 \cdots X_{n+1})$$

$$= da_n(X_1, \ldots, X_{n+1}),$$

where

$$a_n(X_1, \ldots, X_n) = \text{Alt}_{X_1, \ldots, X_n} \text{Tr}(D_q^{-1}X_1X_2 \cdots X_n).$$

This implies that $c_{x,D}^{(n)} = b_n - a_n$ is a cocycle.
Using the presentation
\[ b_n(X_1, \ldots, X_n) = \operatorname{Alt}_{X_1, \ldots, X_n} \int_{\mathbb{R}^n} \text{res} \left( - \sum_{i=1}^{n-1} X_{2i+1} \cdots X_n \xi(X_1)X_2 \cdots l_x(X_{2i}) + \xi(X_1)X_2 \cdots X_{n-1} l_x(X_n) \right) \]
we see that \( b_n \) is continuous when \( q \) tends to 1. The continuity of \( a_n \) follows from identity (4.7) and the continuity of \( c^{(n)} \) as in the proof of Theorem 4.12. □

Results of Feigin [8] give some support to the conjecture of non-triviality of the cocycles above.

5. Deformations of the cocycles.

One can ask how the cohomology is modified under formal deformations. So let \( \mathcal{G}_t \) be a formal deformation of a Lie algebra \( \mathcal{G} = \mathcal{G}_0 \) and \( M_t \) a formal deformation of a \( \mathcal{G} \) module \( M = M_0 \). In the finite dimensional case, one has the “Fuchs principle” which states that the cohomology cannot increase in dimension through deformation: \( \dim H^*(\mathcal{G}_t; M_t) \leq \dim H^*(\mathcal{G}_0; M_0) \). The Hochschild cohomology version of this result is carefully described in the work of M. Gerstenhaber and S. D. Schack [13]. The authors acknowledge the priority of Nijenhuis and Richardson (unpublished) for the Lie algebra cohomology case.

In many cases, the cohomology decreases effectively, and in particular, the cohomology class which leads the deformation gets killed in the cohomology of the deformation; intuitively speaking, formal or actual deformations make cohomology simpler and simpler. But this is not always the case. We shall prove that the Vey class survives in the cohomology of the Lie algebra of pseudo-differential operators.

Let \( (\mathcal{G}_t, M_t) \) be a formal deformation of a Lie algebra and module \( (\mathcal{G}_0, M_0) \) as above. Let \( (C^*_t, d_t) \) and \( (C^*_{0t}, d_0) \) be the corresponding Chevalley-Eilenberg complexes; one has a one parameter family of differentials on the same underlying graded space. Let \( c_t \) be a family of cocycles: \( d(tc_t) = 0 \). If the limit \( c_0 = \lim_{t \to 0} c_t \) is a \( d_0 \)-cocycle (i.e. \( d_0(c_0) = 0 \)) one says that the cohomology class \([c_t]\) contracts onto \([c_0]\).

**Proposition 5.1.** There exists a nontrivial cohomology class \( \tilde{V} \in H^2(\mathfrak{g}, \mathfrak{g}) \) which contracts onto the Vey class \([V] \in H^2(N, N)\).

We shall describe the phenomenon of contraction of cohomology classes by using graded Lie algebra techniques as developed by P.B.A. Lecomte ([27]). Let \( E \) be the underlying vector space of the Lie algebras we consider, and \( A^*(E) \) be the Richardson-Nijenhuis graded Lie algebra on \( E \), whose bracket will be denoted \([\cdot, \cdot] \). The Lie algebra structure \( \mathcal{G}_0 \) is then defined by some \( c_0 \in A^1(E) \) such that \([c_0, c_0] = 0\).

Let \( c_t = c_0 + \sum_{i \geq 1} t^i c_i \) be the formal deformation giving the structure on \( \mathcal{G}_t \); and then \([c_t, c_t] = 0\). This deformation being supposed to be nontrivial, the cocycle \( c_t \) induces a nontrivial cohomology class in \( H^2(\mathcal{G}_0, \mathcal{G}_0) \). One can then construct a cocycle on \( \mathcal{G}_t \).
whose cohomology class contracts onto the class of $c_1$; simply take the formal series given by derivative of $c_t : \dot{c}_t = c_1 + \sum_{i\geq2}^\infty i t^{i-1} c_i$. One obviously has $[[\dot{c}_t, c_1]] = 0$ by derivation of $[[c_t, c_1]] = 0$ and $\dot{c}_t$ contracts onto $c_1$.

Let us check whether the cocycle $\dot{c}_t$ is cohomologically trivial or not for $t > 0$. If so there exists a formal series $a_t \in A^0(E)[[t]]$ such that $\dot{c}_t = [[c_t, a_t]]$. But $a_t$ must be singular at $0$ since $c_0$ is not cohomologically trivial. So let us suppose $a_t = \frac{1}{t} (a_0 + \sum_{t \geq 1} t^i a_i)$. One deduces from $\dot{c}_t = [[c_t, a_t]]$ that

(i) $[[c_0, a_0]] = 0$
(ii) $[[c_0, a_1]] + [[c_1, a_0]] = c_1$

so (i) $a_0$ is a cocycle and (ii) the action of $a_0$ on cohomology leaves the class of $c_1$ invariant (the term $[[c_0, a_1]]$ being nothing but the coboundary of $a_1$).

Straightforward example: let $E = k^3 (k = \mathbb{R} \text{ or } \mathbb{C})$ with basis $X, Y, Z$ and $c_0$ given by $c_0(X, Y) = Z$ and other terms vanishing; so $\mathcal{G}_0$ is the 3 dimensional Heisenberg algebra. Let $c_1$ be given by $c_1(X, Z) = X, c_1(Y, Z) = -Y, c_1(X, Y) = 0$; so $\mathcal{G}_t$ is isomorphic to $s\ell(2, k)$. If $a_0$ is the derivation given by $a_0(X) = X, a_0(Y) = -Y, a_0(Z) = 0$, then $[[c_1, a_0]] = 1$ and so $\dot{c}_t = [[c_t, a_t]]$ which proves that the class given by $c_1$ is killed by the deformation.

Let us consider now $(N, \{,\})$ and the local version of the Richardson-Nijenhuis algebra $A^{1\text{loc}}(N)$ (see [30]). So let $c_1 \in A^{1\text{loc}}(N)$ be the Vey cocycle, defining the infinitesimal part of the Moyal bracket deformation. One should check the 1-cohomology of $N$. It is well known since the first work of Lichnerowicz about deformations of Lie algebras of vector fields that the group $H^1(N, N)$ is isomorphic to the first De Rham cohomology group of the manifold. This isomorphism works as follows: let $\alpha$ be a closed one form on the manifold, it induces a derivation $\alpha$ of $N$ through the formula $\alpha(f) = \alpha(L_f)$. An equivalent way of describing this space is through its isomorphism with the space of symplectic vector fields modulo the space of hamiltonian vector fields (i.e. all multivalued Hamiltonian functions modulo singlevalued Hamiltonian ones). In that case we associate to each symplectic vector field the natural derivation $f \mapsto L_x f$. But then it is straightforward to check that symplectic vector fields respect the Vey cocycles using the geometric description (see [36, 30]). So following the above notations, the condition $[[c_0, a_0]] = 0$ necessarily implies $[[c_1, a_0]] = 0$. Thus the above conditions can never be satisfied, and the Vey class will survive under the deformation.

It would be interesting to generalize those arguments in order to decide whether $[\tilde{V}]$ has a non trivial image in $H^3(\mathfrak{g}; \mathbb{R})$ or not. The situation can again be described through a diagram:

$$
\begin{array}{ccc}
H^2_1(\mathfrak{g}; \mathbb{R}) & \xrightarrow{\theta} & H^3(\mathfrak{g}; \mathbb{R}) \\
\downarrow & & \downarrow \\
H^2_1(N; N) & \xrightarrow{\theta} & H^3(N; \mathbb{R})
\end{array}
$$
where the vertical dotted arrows indicate the contractions. It is easy to check that \( \theta([V]) \) is non trivial in \( H^3(N; \mathbb{R}) \) (see Section 2.1). So the above diagram gives some confidence in the non vanishing of the corresponding class in \( H^3(\mathfrak{g}; \mathbb{R}) \), but the proof is unknown to the authors.

6. The embedding of Virasoro algebra into the completion of \( \mathfrak{g}_q \).

A natural question to ask is whether the standard embedding of vector fields \( \mathfrak{A}(S^1) \) into pseudodifferential symbols \( \mathfrak{g}(S^1) \) can be in some sense quantized, i.e. whether there exists a Lie algebra embedding \( I_q : \mathfrak{A}(S^1) \to \mathfrak{g}_q \) which gives back the standard one as \( q \to 1 \).

If one tries to use the description of \( \psi DO_q \) as a twisted loop algebra ([21]), one identifies the generators of \( \mathfrak{A}(S^1) \) with terms of the form \( x^n D, \ n \in \mathbb{Z} \) belonging to \( A_\sigma [x, x^{-1}] \) (see the above notations) but then one has:

\[
x^n D x^m D = x^{n+m} \sigma^m(D)D
\]

and so

\[
[x^n D, x^m D] = x^{n+m}(\sigma^m(D)D - \sigma^n(D)D) = x^{n+m} \left[([m]_q - [n]_q)D + (q^m - q^n)D^2\right].
\]

This bracket no longer belongs to the image of \( \mathfrak{A}(S^1) \); the space spanned by \( (x^n D)_{n \in \mathbb{Z}} \) is “not closed” in physicist’s language.

We will look for an embedding of the following kind:

\[
I_q : \mathfrak{A}(S^1) \to \hat{\mathfrak{g}}_q \quad \text{given by} \quad I_q(x^{n+1} \frac{\partial}{\partial x}) = x^n f_q(D_q)
\]

into some completion of \( \mathfrak{g}_q \) with analytic \( f_q(D) \) approaching \( D \) when \( q \to 1 \).

Replace \( A = \mathbb{C}[D, D^{-1}] \) by \( \hat{A} = \mathbb{C}[\log D, D][[D^{-1}]] \) with the automorphism

\[
\sigma(D) = qD \quad + 1
\]

\[
\sigma(D^{-1}) = (qD + 1)^{-1} = \sum_{k=1}^{\infty} (-1)^k q^{-k} D^{-k}
\]

\[
\sigma(\log D) = \log(qD + 1) = \log D + \log q + \sum_{k=1}^{\infty} \frac{(-1)^{k-1}}{k} q^{-k} D^{-k}
\]

and then let \( \hat{\mathfrak{g}}_q = \{A \log D + B \mid A, B \in A_\sigma [x, x^{-1}] \} \) to be the Lie subalgebra of \( \hat{A}_\sigma [x, x^{-1}] \). Set

\[
f_q(D) = \frac{\log(1 + D(q - 1))}{\log q} \quad \text{def} \quad \frac{1}{\log q} \left\{ \log D + \log(q - 1) - \sum_{k=1}^{\infty} \frac{1}{k(1 - q)^k} D^{-k} \right\}
\]

and \( I_q : \mathfrak{A}(S^1) \to \hat{\mathfrak{g}}_q \) given by \( I_q(x^{n+1} \frac{\partial}{\partial x}) = x^n f_q(D) \). So

\[
\left[ I_q \left(x^{n+1} \frac{\partial}{\partial x}\right), I_q \left(x^{m+1} \frac{\partial}{\partial x}\right) \right] = x^{n+m} \left[ \sigma^m(f_q(D))f_q(D) - \sigma^n(f_q(D))f_q(D) \right].
\]
Since \( f_q \) is analytic in the neighbourhood of \( D = \infty \), one has

\[
\sigma^m f_q(D) = f_q(\sigma^m(D)) = f_q(q^m D + [m]_q) = \frac{1}{\log q} \log \left(q^m ((q - 1)D + 1)\right).
\]

So

\[
f_q(\sigma^m(D)) - f_q(\sigma^n(D)) = \frac{1}{\log q} \left(\log q^m - \log q^n\right) = (m - n).
\]

Finally

\[
\left[ I_q \left(x^{n+1} \frac{\partial}{\partial x}\right), I_q \left(x^{m+1} \frac{\partial}{\partial x}\right)\right] = (m - n) I_q \left(x^{n+m+1} \frac{\partial}{\partial x}\right) = I_q \left([x^{n+1} \frac{\partial}{\partial x}, x^{m+1} \frac{\partial}{\partial x}]\right).
\]

Now we can check the behaviour of Kac-Radul's cocycle through this homomorphism. Using any trace on \( \hat{A} \), for instance \( \text{Tr} = \text{Tr}_D \) extended to the whole algebra by \( \text{Tr}(D^p(\log D)^k) = 0 \) if \( k > 0 \), one gets:

\[
\psi(I_q(x^{n+1} \frac{\partial}{\partial x}), I_q(x^{m+1} \frac{\partial}{\partial x})) = \text{Tr}\left((1 + \sigma + \ldots + \sigma^{n-1})\sigma^{-n}(f_q(D))f_q(D)\right)
\]

\[
= \text{Tr}\left(\sum_{i=0}^{n-1} (i - n + f_q(D))(i + f_q(D))\right)
\]

\[
= \text{Tr}(1) \sum_{i=0}^{n-1} (i - n)i + \text{Tr}(f_q(D)) \sum_{i=0}^{n-1} (2i - n) + n \text{Tr}(f_q(D)^2)
\]

\[
= \frac{n(n + 1)(n - 1)}{6} \text{Tr}(1) + n \text{Tr}(f_q(D)^2 - f_q(D)).
\]

So one recovers, up to a multiple, the Virasoro cocycle, the last term being a coboundary. Let us denote by \( \hat{\mathfrak{g}}_q \) the central extension of \( \mathfrak{g}_q \), defined through the same cocycle.

**Proposition 6.1.** There exists a Lie algebra homomorphism \( I_q : \text{Vir} \rightarrow \hat{\mathfrak{g}}_q \) such that \( I_q \) tends to the canonical embedding as \( q \rightarrow 1 \).

**Remark 6.1.** For the above isomorphism between \( \mathfrak{g}_q \) and the sine-algebra \( x \mapsto u_1 \) and \( \partial_q + \frac{1}{q-1} \mapsto u_2 \), the map \( I_q \) gives: \( I_q \left(x^n \frac{\partial}{\partial x}\right) = \frac{\log((q-1)u_2)}{\log q} \). So in that context, completion means adding \( \log u_2 \) as a formal supplementary variable.

### 7. q-KP and q-KdV hierarchies.

In this section we define q-analogs for the KP and n-KdV hierarchies and show their "complete integrability". The q-hierarchies in our approach are systems describing commutative flows on the space of q-pseudodifferential operators. In the classical case the extended algebra of integral operators (responsible for the hierarchies) and the centrally extended Lie algebra of differential operators are dual to each other (they are the components of the Manin triple, see [23]). It would be interesting to investigate such a duality for the q-analogs.
7.1. **Classical hierarchies.** Let \( Q \) be a pseudodifferential operator of the form 
\[ Q = \partial + u_1(x)\partial^{-1} + u_2(x)\partial^{-2} + \ldots \]

**Theorem 7.1** (see, e.g. [10]). For any \( m = 1, 2, \ldots \) the system

\[ \frac{\partial Q}{\partial t_m} = [Q, (Q^m)_+] \]  

(7.1)

a) defines an evolution on the space of \( \{Q\} \)
b) is Hamiltonian (with respect to so called first and second Gelfand-Dickey brackets)
c) defines commuting flows for different \( m \).

( c') The corresponding Hamiltonians \( H_m(Q) = \int \text{res}(Q^m) \) are in involution and define
infinite number of conserved quantities for each flow).

**Proof.** We prove here the statements a) and c), which later on are generalized to the case of \( q \)-analogs.

a) We need to show that the vector \([Q, (Q^m)_+]\) belongs to the tangent space of \( \{Q\} \), i.e. that its differential part vanishes. Indeed, \([Q, (Q^m)_+] = [Q, (Q^m)_-], \) and deg\([Q, (Q^m)_-] = \text{deg } Q + \text{deg } (Q^n)_- - 1 = -1, \) i.e. this is an integral operator.

c) Straightforward simple calculation:

\[ \frac{\partial H_m(Q)}{\partial t_k} = \int \text{res} \frac{\partial Q^n}{\partial t_k} = \int \text{res} \sum_{j=0}^{n} Q^j \frac{\partial Q}{\partial t_k} Q^{n-j-1} \]

\[ = \int \text{res} \sum_{j=0}^{n} (Q^j [Q, (Q^k)_+] Q^{n-j-1}) = \int \text{res} [Q^n, (Q^k)_+] = 0 \]

The last identity is due to the ad-invariance of trace: the residue of any commutator is a full derivative. \( \square \)

**Remark 7.1.** The classical KP equation is the compatibility equation for the flows \( \{ \frac{\partial \psi}{\partial t_m} = (Q^m)_+ \psi \} \) for \( m = 2 \) and \( 3 \) (see [10]):

\[ \frac{\partial (Q^3)_+}{\partial t_2} - \frac{\partial (Q^2)_+}{\partial t_3} = [(Q^3)_+, (Q^2)_+] \]  

(7.2)

This is a system of two equations on the coefficients \( \{u_1, u_2\} \), from which one function can be excluded.

**Remark 7.2.** In the same way the phase space of the \( n \)-KdV hierarchy is the set of differential operators \( \{L = \partial^n + u_{n-2}\partial^{n-2} + \cdots + u_0\} \). For any operator \( L \) there exists the only pseudodifferential operator \( Q \) such that \( Q^n = L, \) see [10] (notation: \( Q = L^{1/n} \)). Then the \( m^{th} \) flow of the \( n \)-KdV hierarchy is the system on the coefficients of \( L \) :

\[ \frac{\partial L}{\partial t_m} = [L, (L^{m/n})_+] \]  

(7.3)
Theorem 7.2 (see [2, 10]). This system

a) is well-defined
b) is Hamiltonian
c) has infinite number of conserved quantities

\[ H_k(L) = \int \text{res}(L^{k/n}). \]

Proof. To check a) note that by definition
\[ [L, (L^{m/n})] = -[L, (L^{m/n})], \]
and
\[ \text{deg}[L, (L^{m/n})] = \text{deg}L + \text{deg}(L^{m/n}) - 1 = n - 1 - 1 = n - 2, \]
i.e. this is an element of the tangent space of \{L\}.

The statement c) follows from theorem above and the fact that \( n \)-KdV flows are the KP flows restricted to the set of those operators \{Q\}, whose \( n \)th power is a purely differential operator:
\[ \partial L / \partial t_m = [Q, (Q^m)^+] = [L, (L^{m/n})]. \]

Remark 7.3. The classical KdV equation is the first nontrivial equation in the hierarchy on the space \{L = \partial^2 + u(x)\} (here \( n = 2, m = 3 \)).

7.2. \( q \)-hierarchies. The consideration above almost literally can be applied to the associative algebra of \( q \)-pseudodifferential symbols. The phase space for a \( q \)-KP hierarchy is the set \[ Q_q = \partial_q + u_0(x) + u_1(x)\partial_q^{-1} + u_2(x)\partial_q^{-2} + \ldots \], and the corresponding system has the same form
\[ \partial Q_q / \partial t_m = [Q, (Q^m)^+] \]
where + means taking purely differential part of \( q \)-pseudodifferential operators. This is a mixed system of differential equations on the coefficients of \( \partial_q^j \) \( (q \)-difference operators).

Theorem 7.3. The system (7.4) for any \( m \) defines an evolution on the space \( \{Q_q\} \). For any \( m \) there is an infinite number of conservation laws
\[ H^{(q)}_m(Q_q) = \int \text{res}(Q^m E) \]
and the flows commute for different \( m \).

Proof. Likewise \[ [Q, (Q^m)^+] = -[Q, (Q^m)^-], \]
and thus \[ \text{deg} \partial Q_q / \partial t_m = \text{deg}Q_q + \text{deg}(Q^m)^- = 1 - 1 = 0. \] Now we do not have the cancellation of the leading term in the commutator of \( q \)-symbols. This is why we consider here the space of operators \{Q_q\} containing arbitrary subleading terms \( u_0(x) \). The same calculation as in the classical case verifies the invariance of \( H^{(q)}_m(Q_q) \). We use the \( ad \)-invariance of the trace Tr for \( q \)-operators.

Remark 7.4. The analogous \( q \)-KP equation is the differential system
\[ \partial(Q^3_3)^+ / \partial t_2 - \partial(Q^2_3)^+ / \partial t_3 = [(Q^3_3)^+, (Q^2_3)^+]. \]
It is an overdetermined system, consisting, generally speaking, of 5 equations \( (\text{deg} [(Q^3_3)^+, (Q^2_3)^+] = 5) \) on 3 unknown coefficients \{u_0, u_1, u_2\} of \( Q_q \). The existence of a solution is guaranteed by the Lax formulation above.
To consider a $q$-analog of the $n$-KdV hierarchy we need to define the $n^{th}$ root $Q_q$ of a differential operator $L_q = \partial^n_q + u_{n-1}\partial^{n-1}_q + \cdots + u_0$. However, instead of uniqueness of the exponential map of the “unipotent” group $G$, we have now a sort of “solvable” group $G_q$ of $q$-operators with the surjective but not one-to-one “exponent”. This means that we have a freedom in the choice of the $n^{th}$-root $Q_q$.

Then likewise the $m^{th}$ flow of $n^{th}$ KdV hierarchy

$\frac{\partial L_q}{\partial t_m} = [L_q, (L_q^{m/n})_+]$

for different $m$ the flows commute, and the conserved quantities are $H_k(L_q) = \int \text{res}(L^{k/n}E) = \text{Tr}(L^{k/n})$. Proof repeats the classical case.
