ADDITIVITY NUMBERS OF COVERING PROPERTIES

BOAZ TSABAN

Abstract. The additivity number of a topological property (relative to a given space) is the minimal number of subspaces with this property whose union does not have the property. The most well-known case is where this number is greater than \( \aleph_0 \), i.e. the property is \( \sigma \)-additive. We give a rather complete survey of the known results about the additivity numbers of a variety of topological covering properties, including those appearing in the Scheepers diagram (which contains, among others, the classical properties of Menger, Hurewicz, Rothberger, and Gerlits-Nagy). Some of the results proved here were not published beforehand, and many open problems are posed.

1. Introduction

Assume that \( \mathcal{I} \) is a topological property. For a topological space \( X \), let \( \mathcal{I}(X) \) denote the subspaces of \( X \) which possess the property \( \mathcal{I} \), and assume that \( \bigcup \mathcal{I}(X) \notin \mathcal{I}(X) \). Define the additivity number of \( \mathcal{I} \) (relative to \( X \)) as

\[
\text{add}_X(\mathcal{I}) = \min\{|\mathcal{F}| : \mathcal{F} \subseteq \mathcal{I}(X) \text{ and } \bigcup \mathcal{F} \notin \mathcal{I}(X)\}.
\]

\( \mathcal{I}(X) \) is additive when \( \text{add}_X(\mathcal{I}) \geq \aleph_0 \) and \( \sigma \)-additive when \( \text{add}_X(\mathcal{I}) > \aleph_0 \). Sometimes it is useful to have more precise estimations of the additivity number of a property, or even better, determine it exactly in terms of well-studied cardinals. This is the purpose of this paper. We do that for a variety of topological covering properties, but some restriction is necessary. We concentrate on the case that \( X \) is separable, metrizable, and zero-dimensional. This restriction allows for a convenient application of the combinatorial method. Having established the results for this case, one can seek for generalizations (which are

1991 Mathematics Subject Classification. Primary: 37F20; Secondary 26A03, 03E75.

Key words and phrases. Menger property, Hurewicz property, selection principles, additivity numbers, Rudin-Keisler ordering, near coherence of filters.

sometimes straightforward). Each topological space as above is homeomorphic to a set of irrational numbers. Thus, it suffices to study \( \text{add}_{\mathbb{R}\setminus\mathbb{Q}}(\mathcal{I}) \), and we can therefore omit the subscript.

1.1. **Covering properties.** Fix a space \( X \). An open cover \( \mathcal{U} \) of \( X \) is **large** if each member of \( X \) is contained in infinitely many members of \( \mathcal{U} \). \( \mathcal{U} \) is an \( \omega \)-cover if \( X \notin \mathcal{U} \) and for each finite \( F \subseteq X \), there is \( U \in \mathcal{U} \) such that \( F \subseteq U \). \( \mathcal{U} \) is a \( \gamma \)-cover of \( X \) if it is infinite and for each \( x \in X \), \( x \) is a member of all but finitely many members of \( \mathcal{U} \).

Let \( \mathcal{O}, \Lambda, \Omega, \) and \( \Gamma \) denote the collections of all countable open covers, large covers, \( \omega \)-covers, and \( \gamma \)-covers of \( X \), respectively. Similarly, let \( \mathcal{B}, \mathcal{B}_\Lambda, \mathcal{B}_\Omega, \) and \( \mathcal{B}_\Gamma \) denote the corresponding countable Borel covers of \( X \). Let \( \mathcal{A} \) and \( \mathcal{B} \) be any of these classes. We consider the following three properties which \( X \) may or may not have.

\[ S_1(\mathcal{A}, \mathcal{B}): \text{For each sequence } \{U_n\}_{n \in \mathbb{N}} \text{ of members of } \mathcal{A}, \text{ there exist members } U_n \in U_n, n \in \mathbb{N}, \text{ such that } \{U_n : n \in \mathbb{N}\} \in \mathcal{B}. \]

\[ S_{\text{fin}}(\mathcal{A}, \mathcal{B}): \text{For each sequence } \{U_n\}_{n \in \mathbb{N}} \text{ of members of } \mathcal{A}, \text{ there exist finite subsets } F_n \subseteq U_n, n \in \mathbb{N}, \text{ such that } \bigcup_{n \in \mathbb{N}} F_n \in \mathcal{B}. \]

\[ U_{\text{fin}}(\mathcal{A}, \mathcal{B}): \text{For each sequence } \{U_n\}_{n \in \mathbb{N}} \text{ of members of } \mathcal{A} \text{ which do not contain a finite subcover, there exist finite subsets } F_n \subseteq U_n, n \in \mathbb{N}, \text{ such that } \{\bigcup F_n : n \in \mathbb{N}\} \in \mathcal{B}. \]

Each of these properties, where \( \mathcal{A}, \mathcal{B} \) range over \( \mathcal{O}, \Lambda, \Omega, \Gamma \) or over \( \mathcal{B}, \mathcal{B}_\Lambda, \mathcal{B}_\Omega, \mathcal{B}_\Gamma \), is either void or equivalent to one in Figure 1 (where an arrow denotes implication). For these properties, \( \mathcal{O} \) can be replaced anywhere by \( \Lambda \) and \( \mathcal{B} \) by \( \mathcal{B}_\Lambda \) without changing the property [26, 21, 29].

The **critical cardinality** of a property \( \mathcal{I} \) (relative to a space \( X \)) is

\[ \text{non}_X(\mathcal{I}) = \min\{|Y| : Y \subseteq X \text{ and } Y \notin \mathcal{I}(X)\}. \]

The **covering number** of \( \mathcal{I} \) (relative to \( X \)) is

\[ \text{cov}_X(\mathcal{I}) = \min\{|\mathcal{F}| : \mathcal{F} \subseteq \mathcal{I}(X) \text{ and } \bigcup \mathcal{F} = X\}. \]

Again, since we can work in \( \mathbb{R} \setminus \mathbb{Q} \), we remove the subscript \( X \) from both notations. Below each property in Figure 1 appears its critical cardinality (these cardinals are well studied, see [8]. By \( \mathcal{M} \) we always denote the ideal of meager, i.e. first category, sets of real numbers).

\( S_{\text{fin}}(\mathcal{O}, \mathcal{O}), U_{\text{fin}}(\mathcal{O}, \Gamma), S_1(\mathcal{O}, \mathcal{O}) \) are the classical properties of Menger, Hurewicz, and Rothberger (traditionally called \( C'' \)), respectively. \( S_1(\Omega, \Gamma) \) is the Gerlits-Nagy \( \gamma \)-property. Additional properties in the diagram were studied by Arkhangel’skii, Sakai, and others. Some of the properties are relatively new.

\(^1\)By *open cover* (respectively, *Borel cover*) we mean a cover whose elements are open (respectively, Borel).
We also consider the following type of properties.

**Split**\(\mathcal{A}, \mathcal{B}\): Every cover \(\mathcal{U} \in \mathcal{A}\) can be split into two disjoint subcovers \(\mathcal{V}\) and \(\mathcal{W}\), each containing some element of \(\mathcal{B}\) as a subset.

Here too, letting \(\mathcal{A}, \mathcal{B}\) range over \(\Lambda, \Omega, \Gamma\) or \(\mathcal{B}_\Lambda, \mathcal{B}_\Omega, \mathcal{B}_\Gamma\), we get that some of the properties are trivial and several equivalences hold among the remaining ones. The surviving properties appear in the following diagram (where again the critical cardinality appears below each property).
No implication can be added to this diagram \[^{[33]}\]. There are connections between the first and the second diagram, e.g., $\text{Split}(\Omega, \Gamma) = S_1(\Omega, \Gamma) \[^{[33]}\]$, and both $U_{\text{fin}}(\Omega, \Gamma)$ and $S_1(\Omega, \Omega)$ imply $\text{Split}(\Lambda, \Lambda)$. Similarly, $S_1(\Omega, \Omega)$ implies $\text{Split}(\Omega, \Omega) \[^{[26]}\]$. Similar assertions hold in the Borel case \[^{[33]}\].

The situation becomes even more interesting when $\tau$-covers are incorporated into the framework. We will introduce this notion later.

2. Positive results

2.1. On the Scheepers diagram.

**Proposition 2.1** (folklore). Each property of the form $\Pi(\mathcal{A}, \mathcal{O})$ (or $\Pi(\mathcal{A}, \mathcal{B})$, $\Pi \in \{S_1, S_{\text{fin}}, U_{\text{fin}}\}$, is $\sigma$-additive.

*Proof.* Let $A_1, A_2, \ldots$ be a partition of $\mathbb{N}$ into disjoint infinite sets. Assume that $X_1, X_2, \ldots$ satisfy $\Pi(\mathcal{A}, \mathcal{O})$. Assume that $U_1, U_2, \ldots \in \mathcal{A}$ for $X = \bigcup_{k \in \mathbb{N}} X_k$. For each $k$, use this property of $X_k$ to extract from the sequence $\{U_n\}_{n \in A_k}$ the appropriate cover $V_k$ of $X_k$. Then $\bigcup_{k \in \mathbb{N}} V_k$ is the desired cover of $X$.

The proof for $\Pi(\mathcal{A}, \mathcal{B})$ is identical. \[\Box\]

**Proposition 2.2.** If $\mathcal{I}$ and $\mathcal{J}$ are collections of sets of reals such that:

- $X \in \mathcal{I}$ if, and only if, for each Borel function $\Psi : X \rightarrow \mathbb{R} \setminus \mathbb{Q}$, $\Psi[X] \in \mathcal{J}$.

Then $\text{add}(\mathcal{J}) \leq \text{add}(\mathcal{I})$.

*Proof.* Assume that $X_\alpha, \alpha < \kappa$, are members of $\mathcal{I}$ such that $X = \bigcup_{\alpha < \kappa} X_\alpha \notin \mathcal{I}$. Take a Borel function $\Psi : X \rightarrow \mathbb{R} \setminus \mathbb{Q}$ such that $\Psi[X] \notin \mathcal{J}$. Then $\Psi[X] = \bigcup_{\alpha < \kappa} \Psi[X_\alpha]$. \[\Box\]

It is easy to see that for all $x, y \in \{\Gamma, \Omega, \mathcal{O}\}$, $X$ satisfies $\Pi(B_x, B_y)$ if, and only if, every Borel image of $X$ satisfies $\Pi(x, y)$ (here $B_\mathcal{O} := B$) \[^{[29]}\] \[^{[32]}\]. Using this and the facts that for each property $\mathcal{I}$, $\text{add}(\mathcal{I})$ is a regular cardinal satisfying $\text{add}(\mathcal{I}) \leq \text{cf}\big(\text{non}(\mathcal{I})\big)$ and $\text{add}(\mathcal{I}) \leq \text{cov}(\mathcal{I})$, we have the following.

**Corollary 2.3.**

1. \[\text{add}(S_1(\Omega, \mathcal{O})) \leq \text{add}(S_1(\mathcal{B}, \mathcal{B})) \leq \text{cf}(\text{cov}(\mathcal{M})),\]
2. \[\text{max}\{\text{add}(S_1(\Gamma, \mathcal{O})), \text{add}(U_{\text{fin}}(\mathcal{O}, \Gamma))\} \leq \text{add}(S_1(B_{\mathcal{O}}, B_{\mathcal{O}})) \leq b,\]
3. \[\text{max}\{\text{add}(S_1(\Gamma, \mathcal{O})), \text{add}(S_{\text{fin}}(\mathcal{O}, \mathcal{O}))\} \leq \text{add}(S_{\text{fin}}(\mathcal{B}, \mathcal{B})) \leq \text{cf}(\mathcal{O}),\]
4. \[\text{add}(S_1(\Omega, \Gamma)) \leq \text{add}(S_1(B_{\mathcal{O}}, B_{\mathcal{O}})) \leq p,\]
5. \[\text{max}\{\text{add}(S_1(\Gamma, \Omega)), \text{add}(S_{\text{fin}}(\Gamma, \Omega)), \text{add}(U_{\text{fin}}(\mathcal{O}, \Omega))\} \leq \text{add}(S_1(B_{\mathcal{O}}, B_{\mathcal{O}})) \leq \text{cf}(\mathcal{O}).\] \[\Box\]
We now look for lower bounds on the additivity numbers. Define a partial order \( f \leq^* g \) if \( f(n) \leq g(n) \) for all but finitely many \( n \).

A subset of \( \mathbb{N}^\mathbb{N} \) is called \emph{bounded} if it is bounded with respect to \( \leq^* \).

A subset \( D \) of \( \mathbb{N}^\mathbb{N} \) is \emph{dominating} if for each \( g \in \mathbb{N}^\mathbb{N} \) there exists \( f \in D \) such that \( g \leq^* f \).

View \( \mathbb{N} \) as a discrete topological space. The \emph{Baire space} is the product space \( \mathbb{N}^\mathbb{N} \). Hurewicz \((17, \text{ see also Reclaw } 25)\) proved that a set of reals \( X \) satisfies \( S_{\text{fin}}(\mathcal{O}, \mathcal{O}) \) if, and only if, every continuous image of \( X \) in \( \mathbb{N}^\mathbb{N} \) is not dominating. Likewise, he showed that \( X \) satisfies \( U_{\text{fin}}(\mathcal{O}, \Gamma) \) if, and only if, every continuous image of \( X \) in \( \mathbb{N}^\mathbb{N} \) is bounded. Replacing “continuous image” by “Borel image” we get characterizations of \( S_{\text{fin}}(\mathcal{B}, \mathcal{B}) \) and \( S_1(\mathcal{B}_\Gamma, \mathcal{B}_\Gamma) \), respectively \([29]\). It is easy to see that a union of less than \( b \) many bounded subsets of \( \mathbb{N}^\mathbb{N} \) is bounded, and a union of less than \( b \) many subsets of \( \mathbb{N}^\mathbb{N} \) which are not dominating is not dominating.

**Corollary 2.4.**

\( \begin{align*}
1 & \quad \text{add}(U_{\text{fin}}(\mathcal{O}, \Gamma)) = \text{add}(S_1(\mathcal{B}_\Gamma, \mathcal{B}_\Gamma)) = b; \\
2 & \quad b \leq \text{add}(S_{\text{fin}}(\mathcal{O}, \mathcal{O})) \leq \text{add}(S_{\text{fin}}(\mathcal{B}, \mathcal{B})) \leq \text{cf}(\emptyset). \quad \Box
\end{align*} \)

Consider an unbounded subset \( B \) of \( \mathbb{N}^\mathbb{N} \) such that \( |B| = b \), and define, for each \( f \in B \), \( Y_f = \{ g \in \mathbb{N}^\mathbb{N} : f \not\leq^* g \} \). Then the sets \( Y_f \) are not dominating, but \( \bigcup_{f \in B} Y_f = \mathbb{N}^\mathbb{N} \): For each \( g \in \mathbb{N}^\mathbb{N} \) there exists \( f \in B \) such that \( f \not\leq^* g \), that is, \( g \in Y_f \). Thus the second assertion in Corollary 2.4 cannot be strengthened in a trivial manner. We must work harder for that.

Let \( [\mathbb{N}]^{\aleph_0} \) denote the collection of all infinite sets of natural numbers. For \( a, b \in [\mathbb{N}]^{\aleph_0} \), \( a \) is an \emph{almost subset} of \( b \), \( a \subseteq^* b \), if \( a \setminus b \) is finite. A family \( G \subseteq [\mathbb{N}]^{\aleph_0} \) is \emph{groupwise dense} if it contains all almost subsets of its elements, and for each partition of \( \mathbb{N} \) into finite intervals (i.e., sets of the form \( \{m, k\} = \{m, m+1, \ldots, k-1\} \)), there is an infinite set of intervals in this partition whose union is a member of \( G \).

\( [\mathbb{N}]^{\aleph_0} \) is a topological subspace of \( P(\mathbb{N}) \), where the topology on \( P(\mathbb{N}) \) is defined by identifying it with the Cantor space \( \{0, 1\}^\mathbb{N} \). For each finite \( F \subseteq \mathbb{N} \) and each \( n \in \mathbb{N} \), define

\[ O_{F,n} = \{ a \in P(\mathbb{N}) : a \cap [0, n) = F \}. \]

The sets \( O_{F,n} \) form a clopen basis for the topology on \( P(\mathbb{N}) \).

For \( a \in [\mathbb{N}]^{\aleph_0} \), define an element \( a^+ \) of \( \mathbb{N}^\mathbb{N} \) by

\[ a^+(n) = \min\{k \in a : n < k\} \]
for each \( n \).

**Theorem 2.5** (Tsaban-Zdomskyy [35]). Assume that \( X \) satisfies \( S_{\text{fin}}(\mathcal{O},\mathcal{O}) \). Then for each continuous image \( Y \) of \( X \) in \( \mathbb{N}^\mathbb{N} \), the family
\[
G = \{ a \in [\mathbb{N}]^{\aleph_0} : (\forall f \in Y) \ a^+ \not\leq^* f \}
\]
is groupwise dense.

**Proof.** Assume that \( Y \) is a continuous image of \( X \) in \( \mathbb{N}^\mathbb{N} \). Then \( Y \) satisfies \( S_{\text{fin}}(\mathcal{O},\mathcal{O}) \).

**Lemma 2.6** (folklore). Assume that \( X \) satisfies \( S_{\text{fin}}(\mathcal{O},\mathcal{O}) \) and \( K \) is \( \sigma \)-compact. Then \( X \times K \) satisfies \( S_{\text{fin}}(\mathcal{O},\mathcal{O}) \).

**Proof.** This proof is as in [22]. As \( S_{\text{fin}}(\mathcal{O},\mathcal{O}) \) is \( \sigma \)-additive, we may assume that \( K \) is compact. Assume that \( U_1, U_2, \ldots \) are countable open covers of \( X \times K \). For each \( n \), enumerate \( U_n = \{ U^n_m : m \in \mathbb{N} \} \). For each \( n \) and \( m \) set
\[
V^n_m = \left\{ x \in X : \{ x \} \times K \subseteq \bigcup_{k \leq m} U^n_k \right\}.
\]
Then \( V_n = \{ V^n_m : m \in \mathbb{N} \} \) is an open cover of \( X \). As \( X \) satisfies \( S_{\text{fin}}(\mathcal{O},\mathcal{O}) \), we can choose for each \( n \) an \( m_n \) such that \( X = \bigcup_n \bigcup_{k \leq m_n} V^n_k \).

By the definition of the sets \( V^n_k \), \( X \times K \subseteq \bigcup_n \bigcup_{k \leq m_n} U^n_k \). \( \square \)

By Lemma 2.6, \( P(\mathbb{N}) \times Y \) satisfies \( S_{\text{fin}}(\mathcal{O},\mathcal{O}) \).

**Lemma 2.7** ([35]). The set
\[
C = \{ (a, f) \in [\mathbb{N}]^{\aleph_0} \times \mathbb{N}^\mathbb{N} : a^+ \leq^* f \}
\]
is an \( F_\sigma \) subset of \( P(\mathbb{N}) \times \mathbb{N}^\mathbb{N} \).

**Proof.** Note that
\[
C = \bigcup_{m \in \mathbb{N}} \bigcap_{n \geq m} \{ (a, f) \in P(\mathbb{N}) \times \mathbb{N}^\mathbb{N} : (n, f(n)] \cap a \neq \emptyset \}.
\]
(The nonempty intersection for infinitely many \( n \) allows the replacement of \([\mathbb{N}]^{\aleph_0}\) by \( P(\mathbb{N}) \).

For fixed \( m \) and \( n \), the set \( \{ (a, f) \in P(\mathbb{N}) \times \mathbb{N}^\mathbb{N} : (n, f(n)] \cap a \neq \emptyset \} \) is clopen: Indeed, if \( \lim_k (a_k, f_k) = (a, f) \) then for all large enough \( k \), \( f_k(n) = f(n) \), and therefore for all larger enough \( k \), \( (n, f_k(n)] \cap a_k = (n, f(n)] \cap a \). Thus, \( (a_k, f_k) \) is in the set if, and only if, \( (a, f) \) is in the set. \( \square \)
As $S_{\text{fin}}(\mathcal{O}, \mathcal{O})$ is $\sigma$-additive and hereditary for closed subsets, we have by Lemma 2.7 that $C \cap (P(\mathbb{N}) \times Y)$ satisfies $S_{\text{fin}}(\mathcal{O}, \mathcal{O})$, and therefore so does its projection $Z$ on the first coordinate. By the definition of $Z$, $G = Z^c$, the complement of $Z$ in $[\mathbb{N}]^{\aleph_0}$. Note that $G$ contains all almost subsets of its elements.

For $a \in [\mathbb{N}]^{\aleph_0}$ and an increasing $h \in \mathbb{N}$, define
\[
a/h = \{ n : a \cap [h(n), h(n+1)) \neq \emptyset \}.
\]
For $S \subseteq [\mathbb{N}]^{\aleph_0}$, define $S/h = \{ a/h : a \in S \}$.

**Lemma 2.8** ([35]). Assume that $G \subseteq [\mathbb{N}]^{\aleph_0}$ contains all almost subsets of its elements. Then: $G$ is groupwise dense if, and only if, for each increasing $h \in \mathbb{N}$, $G^c/h \neq [\mathbb{N}]^{\aleph_0}$.

**Proof.** For each increasing $h \in \mathbb{N}$ and each $a \in [\mathbb{N}]^{\aleph_0}$,
\[
\bigcup_{n \in a} [h(n), h(n+1)) \notin G \iff \bigcup_{n \in a} [h(n), h(n+1)) \in G^c \iff a \in G^c/h.
\]
The lemma follows directly from that. \qed

Assume that $G$ is not groupwise dense. By Lemma 2.8 there is an increasing $h \in \mathbb{N}$ such that $Z/h = G^c/h = [\mathbb{N}]^{\aleph_0}$. The natural mapping $\Psi : Z \rightarrow Z/h$ defined by $\Psi(a) = a/h$ is a continuous surjection. It follows that $[\mathbb{N}]^{\aleph_0}$ satisfies $S_{\text{fin}}(\mathcal{O}, \mathcal{O})$. But this is absurd: The image of $[\mathbb{N}]^{\aleph_0}$ in $\mathbb{N}$, under the continuous mapping assigning to each $a \in [\mathbb{N}]^{\aleph_0}$ its increasing enumeration, is a dominating subset of $\mathbb{N}$. Thus, $[\mathbb{N}]^{\aleph_0}$ does not satisfy $S_{\text{fin}}(\mathcal{O}, \mathcal{O})$ – a contradiction. \qed

We obtain the promised improvement of Corollary 2.4(2).

**Corollary 2.9** (Zdomskyy [38, 35]). $\max\{b, g\} \leq \text{add}(S_{\text{fin}}(\mathcal{O}, \mathcal{O})) \leq \text{add}(S_{\text{fin}}(\mathcal{B}, \mathcal{B})) \leq \text{cf}(\mathcal{B})$.

**Proof.** By Corollary 2.4 we need only show that $g \leq \text{add}(S_{\text{fin}}(\mathcal{O}, \mathcal{O}))$.

Assume that $\kappa < g$ and for each $\alpha < \kappa$, $X_\alpha$ satisfies $S_{\text{fin}}(\mathcal{O}, \mathcal{O})$, and that $X = \bigcup_{\alpha < \kappa} X_\alpha$. By the Hurewicz Theorem, it suffices to show that no continuous image of $X$ in $\mathbb{N}$ is dominating. Indeed, assume that $\Psi : X \rightarrow \mathbb{N}$ is continuous. By Theorem 2.3, for each $\alpha$ the family
\[
G_\alpha = \{ a \in [\mathbb{N}]^{\aleph_0} : (\forall f \in \Psi[X_\alpha]) a^+ \not\leq^* f \}
\]
is groupwise dense. Thus, there exists $a \in \bigcap_{\alpha < \kappa} G_\alpha$. Then $a^+$ witnesses that $\Psi[X]$ is not dominating. \qed

**Problem 2.10.** Is it consistent that $\max\{b, g\} < \text{add}(S_{\text{fin}}(\mathcal{O}, \mathcal{O}))$?
The methods used to obtain the last lower bound are similar to earlier methods of Scheepers used to bound $\text{add}(S_1(\Gamma, \Gamma))$ from below. A family $D \subseteq [N]^{\aleph_0}$ is open if it is closed under almost subsets. It is dense if for each $a \in [N]^{\aleph_0}$ there is $d \in D$ such that $d \subseteq^* a$. The density number $h$ is the minimal cardinality of a collection of open dense families in $[N]^{\aleph_0}$ whose intersection is empty. Identify $[N]^{\aleph_0}$ with the increasing elements of $\mathbb{N}$ by taking increasing enumerations.

**Theorem 2.11 (Scheepers [27]).** Assume that $X$ satisfies $S_1(\Gamma, \Gamma)$, and $U_1, U_2, \ldots$ are open $\gamma$-covers of $X$. For each $n$, enumerate $U_n = \{U^n_m : m \in \mathbb{N}\}$. Then the family of all $a \in [N]^{\aleph_0}$ such that $\{U^n_{a(n)} : n \in \mathbb{N}\}$ is a $\gamma$-cover of $X$ is open dense.

**Proof.** By standard arguments, we may assume that the given $\gamma$-covers are pairwise disjoint (use the fact that any countable sequence of infinite sets can be refined to a countable sequence of pairwise disjoint infinite sets.)

For each $n$ and $m$, define

$$V^n_m = U^n_1 \cap U^n_2 \cap \cdots \cap U^n_m.$$  

Fix any $a \in [N]^{\aleph_0}$. For each $n$, define

$$\gamma_n = \{V^n_{a(m)} : m \geq n\}.$$  

Then $\gamma_n \in \Gamma$. By $S_1(\Gamma, \Gamma)$, there is $f \in \mathbb{N}^\mathbb{N}$ such that $f(n) \geq n$ for all $n$, and $\{\gamma_{f(n)} : n \in \mathbb{N}\} \in \Gamma$.

Let $\tilde{f}$ be such that $\tilde{f}(1) = f(1)$, and for each $n \geq 1$, $\tilde{f}(n + 1) = f(k)$ for some $k > n$ with $\tilde{f}(n) < f(k)$. By the definition of the sets $V^n_m$, $\{V^n_{a(\tilde{f}(n))} : n \in \mathbb{N}\} \in \Gamma$ as well. Let $d \in [N]^{\aleph_0}$ be such that $d(n) = a(\tilde{f}(n))$ for all $n$. Then $d \subseteq a$, and as $\{V^n_{d(n)} : n \in \mathbb{N}\} \in \Gamma$, we have again by the definition of the sets $V^n_m$, that $\{V^n_{a(n)} : n \in \mathbb{N}\} \in \Gamma$ for all $b \subseteq d$. In particular, $\{U^n_{a(n)} : n \in \mathbb{N}\} \in \Gamma$ for all $b \subseteq d$. \hfill $\square$

**Corollary 2.12 (Scheepers [27]).** $h \leq \text{add}(S_1(\Gamma, \Gamma)) \leq \text{add}(S_1(B_\Gamma, B_\Gamma)) \leq b$.

**Proof.** Fix $\kappa < h$ and assume that $X_\alpha, \alpha < \kappa$, all satisfy $S_1(\Gamma, \Gamma)$. Let $X = \bigcup_{\alpha < \kappa} X_\alpha$, and assume that for each $n$, $U_n = \{U^n_m : m \in \mathbb{N}\}$ is an open $\gamma$-cover of $X$.

By Theorem 2.11, for each $\alpha$ the family

$$D_\alpha = \{a \in [N]^{\aleph_0} : \{U^n_{a(n)} : n \in \mathbb{N}\} \text{ is a } \gamma\text{-cover of } X\}$$

is open dense. Take $a \in \bigcap_{\alpha < \kappa} D_\alpha$. Then $\{U^n_{a(n)} : n \in \mathbb{N}\}$ is a $\gamma$-cover of $X$. \hfill $\square$
Problem 2.13. *Is it consistent that \( h < \text{add}(S_1(\Gamma, \Gamma)) \)?

Problem 2.14. *Is it consistent that \( \text{add}(S_1(\Gamma, \Gamma)) < b \)?

We conclude the section with the following beautiful result. Let \( \mathcal{N} \) denote the collection of Lebesgue null sets of reals.

**Theorem 2.15** (Carlson \[2\]). \( \text{add}(\mathcal{N}) \leq \text{add}(S_1(\mathcal{O}, \mathcal{O})) \leq \text{add}(S_1(\mathcal{B}, \mathcal{B})) \leq \text{cf}(\text{cov}(\mathcal{M})). \)

**Proof.** The new ingredient is the first inequality.

**Lemma 2.16** (Bartoszyński \[3\]). \( \text{add}(\mathcal{N}) \) is the smallest cardinality of a family \( F \subseteq \mathbb{N}^{\mathbb{N}} \) such that there is no function \( S : \mathbb{N} \rightarrow [\mathbb{N}]^{<\aleph_0} \) with \( |S(n)| \leq n \) for all \( n \), such that \((\forall f \in F)(\forall^{\infty} n) f(n) \in S(n). \)

Assume that \( \kappa < \text{add}(\mathcal{N}) \) and \( X_\alpha, \alpha < \kappa \), satisfy \( S_1(\mathcal{O}, \mathcal{O}) \). Let \( X = \bigcup_{\alpha < \kappa} X_\alpha \). Assume that \( \mathcal{U}_n = \{ U_m : m \in \mathbb{N} \}, n \in \mathbb{N} \), are open covers of \( X \). Let \( r_n = 1 + 2 + \cdots + (n - 1) \). For each \( n \), let

\[
\tilde{U}_n = \{ \tilde{U}^n_s : s : [r_n, r_{n+1}) \rightarrow \mathbb{N} \},
\]

where \( \tilde{U}^n_s = \bigcap_{k=r_n}^{r_{n+1}} U^k_s(k) \). \( \tilde{U}_n \) is an open cover of \( X \). For each \( \alpha < \kappa \), as \( X_\alpha \) satisfies \( S_1(\mathcal{O}, \mathcal{O}) \), there is \( f_\alpha : \mathbb{N} \rightarrow [\mathbb{N}]^{<\aleph_0} \) such that \( f(n) \in \mathbb{N}^n \) for each \( n \), and \( \{ \tilde{U}^n_{f_\alpha(n)} : n \in \mathbb{N} \} \) is a cover of \( X_\alpha \). By Lemma 2.16, there is \( S : \mathbb{N} \rightarrow [\mathbb{N}]^{<\aleph_0} \) with \( S(n) \in \mathbb{N}^n \) and \( |S(n)| \leq n \) for all \( n \), such that \( (\forall \alpha < \kappa)(\forall^{\infty} n) f_\alpha(n) \in S(n). \)

For each \( n \), \( S(n) \) contains at most \( n \) sequences of length \( n \). Let \( g \in [\mathbb{N}]^\mathbb{N} \) be a function which agrees at least once on the \( n \)-element interval \([r_n, r_{n+1})\) with each of these sequences. Then \( \{ \tilde{U}^n_{g(n)} : n \in \mathbb{N} \} \) is a cover of \( X \).

**2.2. On splitting properties.**

**Theorem 2.17** (\[33\]). Split(\( \mathcal{B}_\Omega, \mathcal{B}_\Lambda \)) and Split(\( \Omega, \Lambda \)) are \( \sigma \)-additive.

**Proof.** We will prove the open case. The Borel case is similar.

**Lemma 2.18** (\[33\]). Assume that \( \mathcal{U} \) is a countable open \( \omega \)-cover of \( Y \) and that \( X \subseteq Y \) satisfies Split(\( \Omega, \Lambda \)). Then \( \mathcal{U} \) can be partitioned into two pieces \( \mathcal{V} \) and \( \mathcal{W} \) such that that \( \mathcal{W} \) is an \( \omega \)-cover of \( Y \) and \( \mathcal{V} \) is a large cover of \( X \).

\(^2\)Added after publication: The answer is positive. Dow proved in \[13\] a theorem implying \[37\] that \( S_1(\Gamma, \Gamma) = S_1(\mathcal{B}_\Gamma, \mathcal{B}_\Gamma) \) (indeed, \( S_1(\mathcal{B}_\Gamma, \mathcal{B}_\Gamma) = |\mathbb{R}|^{<\text{cf}(\mathcal{B}_\Gamma)} \) in that model \[24\]). In Laver’s model, \( h < b \) \[8\]. Apply Corollary 2.4(1).
Proof. First assume that there does not exist $U \in \mathcal{U}$ with $X \subseteq U$. Then $\mathcal{U}$ is an $\omega$-cover of $X$. By the splitting property we can divide it into two pieces each a large cover of $X$. Since $\mathcal{U}$ is an $\omega$-cover of $Y$, one of the pieces is an $\omega$-cover of $Y$, and the lemma is proved. If there are only finitely many $U \in \mathcal{U}$ with $X \subseteq U$, then $\tilde{\mathcal{U}} = \mathcal{U} \setminus \{U \in \mathcal{U} : X \subseteq U\}$ is still an $\omega$-cover of $Y$ and we can apply to it the above argument.

Thus, assume that there are infinitely many $U \in \mathcal{U}$ with $X \subseteq U$. Then take a partition of $\mathcal{U}$ into two pieces such that each piece contains infinitely many sets $U$ with $X \subseteq U$. One of the pieces must be an $\omega$-cover of $Y$. $\square$

Proposition 2.2 implies the following.

Corollary 2.19. (1) $\text{add}(\text{Split}(\Lambda, \Lambda)) \leq \text{add}(\text{Split}(B\Lambda, B\Lambda)) \leq \text{cf}(\tau)$,
(2) $\text{add}(\text{Split}(\Omega, \Lambda)) \leq \text{add}(\text{Split}(B\Omega, B\Lambda)) \leq \text{cf}(\omega)$,
(3) $\text{add}(\text{Split}(\Omega, \Omega)) \leq \text{add}(\text{Split}(B\Omega, B\Omega)) \leq \text{cf}(\omega)$. $\square$

However, $\text{Split}(\Omega, \Omega)$ and $\text{Split}(B\Omega, B\Omega)$ are not provably additive, as we shall see in Section 3.

Concerning $\sigma$-additivity (or even just additivity, i.e. $\aleph_0$-additivity), exactly one question remains open.

Problem 2.20. Is $\text{Split}(\Lambda, \Lambda)$ provably additive? What about the Borel case?

3. Consistently negative results

Showing that a certain class is not additive is apparently harder: All known results require axioms beyond ZFC. This is often necessary, as will be seen in Section 4.

3.1. On the Scheepers diagram. For a sequence $\{X_n\}_{n \in \mathbb{N}}$ of subsets of $X$, define $\liminf X_n = \bigcup_m \bigcap_{n \geq m} X_n$. For a family $\mathcal{U}$ of subsets of $X$, $L(\mathcal{U})$ denotes its closure under the operation $\liminf$. A set of reals $X$ has the property $(\delta)$ if for each open $\omega$-cover $\mathcal{U}$ of $X$, $X \in L(\mathcal{U})$. The property $(\delta)$ was introduced by Gerlits and Nagy in [16], where they showed that $S_1(\Omega, \Gamma)$ implies $(\delta)$. The converse implication is still
open. It seems that the fact that $(\delta)$ is not provably additive was not noticed before, but if follows from a combination of results from \[12\], \[15\], as we now show.

**Theorem 3.1.** Assume the Continuum Hypothesis. Then no class between $S_1(B_{\Omega}, B_{\Gamma})$ and $S_1(\Omega, \Gamma)$ or even $(\delta)$ (inclusive) is additive.

*Proof.* By a theorem of Brendle \[12\], assuming CH there exists a set of reals $X$ of size continuum such that all subsets of $X$ satisfy $S_1(B_{\Omega}, B_{\Gamma})$.

As $S_1(B_{\Omega}, B_{\Gamma})$ is closed under taking Borel (continuous is enough) images, we may assume that $X \subseteq (0, 1)$. For $Y \subseteq (0, 1)$, write $Y + 1 = \{y + 1 : y \in Y\}$ for the translation of $Y$ by 1. The following is essentially proved in Theorem 5 of Galvin and Miller’s paper \[15\].

**Lemma 3.2.** If $Y \subseteq X \subseteq (0, 1)$ and $Z = (X \setminus Y) \cup (Y + 1)$ has property $(\delta)$, then $Y$ is a Borel subset of $X$.

*Proof.* Let

$$U = \{U \cup (V + 1) : \text{open } U, V \subseteq (0, 1), \overline{U} \cap \overline{V} = \emptyset\}.$$ 

$U$ is an open $\omega$-cover of $Z$. If $U_n \cap V_n = \emptyset$ for all $n$, then the sets $U = \bigcup_{n \geq m} U_n$ and $V = \bigcup_{n \geq m} V_n$ are disjoint, and $\bigcup_{n \geq m} U_n \cup (V_n + 1) = U \cup (V + 1)$. It follows by transfinite induction, each element in $L(U)$ has the form $U \cup (V + 1)$ where $U, V$ are disjoint Borel subsets of $Z$. Thus, if $Z \in L(U)$, there are such $U$ and $V$ with $Z = U \cup (V + 1)$. It follows that $Y = V \cap X$ is a Borel subset of $X$. \[\square\]

As $|X| = \mathfrak{c}$ and only $\mathfrak{c}$ many out of the $2^\mathfrak{c}$ many subsets of $X$ are Borel, there exists a subset $Y$ of $X$ which is not Borel. It follows that $(X \setminus Y) \cup (Y + 1)$ does not have the property $(\delta)$ (and, in particular, does not have the property $S_1(\Omega, \Gamma)$). But by the choice of $X$, both $X \setminus Y$ and $Y$ (and therefore also $Y + 1$) satisfy $S_1(B_{\Omega}, B_{\Gamma})$. \[\square\]

Except for the $(\delta)$ part, Theorem 3.1 was proved in \[31\]. The extension to $(\delta)$ was noticed by Miller (personal communication).

We next show that if $\text{cov}(\mathcal{M}) = \mathfrak{c}$ (in particular, assuming the Continuum Hypothesis), then no class between $S_1(B_{\Omega}, B_{\Omega})$ and $U_{fin}(\mathcal{O}, \Omega)$ (inclusive) is additive.

For clarity of exposition, we will first treat the open case, and then explain how to modify the constructions in order to cover the Borel case.

For convenience, we will work in $\mathbb{Z}^\mathbb{N}$ (with pointwise addition), which is homeomorphic to $\mathbb{R} \setminus \mathbb{Q}$. The notions that we will use are topological, thus the following constructions can be translated to constructions in $\mathbb{R} \setminus \mathbb{Q}$. 

A collection $\mathcal{J}$ of sets of reals is translation invariant if for each real $x$ and each $X \in \mathcal{J}$, $x + X \in \mathcal{J}$. $\mathcal{J}$ is negation invariant if for each $X \in \mathcal{J}$, $-X \in \mathcal{J}$ as well. For example, $\mathcal{M}$ and $\mathcal{N}$ are negation and translation invariant (and there are many more examples).

**Lemma 3.3** (folklore). If $\mathcal{J}$ is negation and translation invariant and if $X$ is a union of less than $\text{cov}(\mathcal{J})$ many elements of $\mathcal{J}$, then for each $x \in \mathbb{Z}^N$ there exist $y, z \in \mathbb{Z}^N \setminus X$ such that $y + z = x$.

**Proof.** $(x - X) \cup X$ is a union of less than $\text{cov}(\mathcal{J})$ many elements of $\mathcal{J}$. Thus we can choose an element $y \in \mathbb{Z}^N \setminus ((x - X) \cup X) = (x - \mathbb{Z}^N \setminus X) \cap (\mathbb{Z}^N \setminus X)$; therefore there exists $z \in \mathbb{Z}^N \setminus X$ such that $x - z = y$, that is, $x = y + z$. □

A set of reals $L$ is $\kappa$-Luzin if $|L| \geq \kappa$ and for each meager set $M$, $|L \cap M| < \kappa$.

The following result was obtained independently by many authors: A comment on the top of Page 205 of [21] (without proof); Theorem 13 of [28] (under the Continuum Hypothesis); Section 3 of [22]; Theorem 2 of [14] (under the Continuum Hypothesis).

**Proposition 3.4** (folklore). Assume that $\text{cov}(\mathcal{M}) = \mathfrak{c}$. Then there exist $\mathfrak{c}$-Luzin subsets $L_0$ and $L_1$ of $\mathbb{Z}^N$ satisfying $S_1(\Omega, \Omega)$, such that $L_0 + L_1 = \mathbb{Z}^N$.

**Proof.** Assume that $\text{cov}(\mathcal{M}) = \mathfrak{c}$. Let $\{y_\alpha : \alpha < \mathfrak{c}\}$ enumerate $\mathbb{Z}^N$; let $\{M_\alpha : \alpha < \mathfrak{c}\}$ enumerate all $F_\sigma$ meager sets in $\mathbb{Z}^N$ (observe that this family is cofinal in $\mathcal{M}$), and let $\{\{U_{\alpha}^n\}_{n \in \mathbb{N}} : \alpha < \mathfrak{c}\}$ enumerate all countable sequences of countable families of open sets.

Fix a countable dense subset $Q \subseteq \mathbb{Z}^N$. We construct $L_0 = \{x_\beta^0 : \beta < \mathfrak{c}\} \cup Q$ and $L_1 = \{x_\beta^1 : \beta < \mathfrak{c}\} \cup Q$ by induction on $\alpha < \mathfrak{c}$. During the construction, we make an inductive hypothesis and verify that it remains true after making the inductive step.

At stage $\alpha \geq 0$ set

$$
X_\alpha^0 = \{x_\beta^0 : \beta < \alpha\} \cup Q
$$

$$
X_\alpha^1 = \{x_\beta^1 : \beta < \alpha\} \cup Q
$$

and consider the sequence $\{U_{\alpha}^n\}_{n \in \mathbb{N}}$. For each $i < 2$, do the following. Call $\alpha$ $i$-good if for each $n \in \mathbb{N}$, $U_{\alpha}^n$ is an $\omega$-cover of $X_{\alpha}^i$. Assume that $\alpha$ is $i$-good. Since $\text{cov}(\mathcal{M}) = \text{non}(S_1(\Omega, \Omega))$ [21] and we assume that $\text{cov}(\mathcal{M}) = \mathfrak{c}$, there exist elements $U_\alpha^{\alpha,i} \subseteq U_{\alpha}^n$ such that $\{U_{\alpha}^n\}_{n \in \mathbb{N}}$ is an $\omega$-cover of $X_{\alpha}^i$. We make the inductive hypothesis that for each $i$-good $\beta < \alpha$, $\{U_{\beta}^{\beta,i}\}_{n \in \mathbb{N}}$ is an $\omega$-cover of $X_{\alpha}^i$. For each finite $F \subseteq X_{\alpha}^i$, and
each \(i\)-good \(\beta \leq \alpha\), define
\[
G_i^{F,\beta} = \bigcup \{U_n^{\beta,i} : n \in \mathbb{N}, F \subseteq U_n^{\beta,i}\}.
\]

Then \(Q \subseteq G_i^{F,\beta}\) and thus \(G_i^{F,\beta}\) is open and dense.

Set
\[
Y_\alpha = \bigcup_{\beta < \alpha} M_\beta \cup \bigcup_{i < 2, \beta \leq \alpha} \{Z \setminus G_i^{F,\beta} : i < 2, \beta \leq \alpha, i\text{-good}, F \subseteq X_i^\alpha\text{ finite}\}.
\]

Then \(Y_\alpha\) is a union of less than \(\text{cov}(\mathcal{M})\) many meager sets, thus by Lemma 3.3 we can pick \(x_0^\alpha, x_1^\alpha \in \mathbb{Z}^\mathbb{N} \setminus Y_\alpha\) such that \(x_0^\alpha + x_1^\alpha = y_\alpha\). To see that the inductive hypothesis is preserved, observe that for each finite \(F \subseteq X_i^\alpha\) and \(i\)-good \(\beta \leq \alpha\), \(x_i^\alpha \in G_i^{F,\beta}\) and therefore \(F \cup \{x_i^\alpha\} \subseteq U_n^{\beta,i}\) for some \(n\).

Clearly \(L_0\) and \(L_1\) are \(c\)-Luzin sets, and \(L_0 + L_1 = \mathbb{Z}^\mathbb{N}\). It remains to show that \(L_0\) and \(L_1\) satisfy \(S_1(\Omega, \Omega)\).

Fix \(i < 2\). Consider, for each \(\beta < c\), the sequence \(\{U_n^\beta\}_{n \in \mathbb{N}}\). If all members of that sequence are \(\omega\)-covers of \(L_i\), then in particular they \(\omega\)-cover \(X_i^\beta\) (that is, \(\beta\) is \(i\)-good). By the inductive hypothesis, \(\{U_n^{\beta,i} : n \in \mathbb{N}\}\) is an \(\omega\)-cover of \(X_i^\alpha\) for each \(\alpha < c\), and therefore an \(\omega\)-cover of \(L_i\). \(\Box\)

For a finite subset \(F\) of \(\mathbb{N}^\mathbb{N}\), define \(\max(F) \in \mathbb{N}^\mathbb{N}\) to be the function \(g\) such that \(g(n) = \max\{f(n) : f \in F\}\) for each \(n\). A subset \(Y\) of \(\mathbb{N}^\mathbb{N}\) is \textit{finitely-dominating} if the collection
\[
\max\text{fin}(Y) := \{\max(F) : F \text{ is a finite subset of } Y\}
\]
is dominating.

**Theorem 3.5** (Tsaban [32], Eisworth-Just [14]). For a set of reals \(X\), the following are equivalent:

1. \(X\) satisfies \(\text{U}_{\text{fin}}(\mathcal{O}, \Omega)\);
2. No continuous image of \(X\) in \(\mathbb{N}^\mathbb{N}\) is finitely-dominating. \(\Box\)

A subset \(Y\) of \(\mathbb{N}^\mathbb{N}\) is \(k\)-dominating if for each \(g \in \mathbb{N}^\mathbb{N}\) there exists a \(k\)-element subset \(F\) of \(Y\) such that \(g \leq^* \max(F)\) [9]. Clearly each \(k\)-dominating subset of \(\mathbb{N}^\mathbb{N}\) is also finitely dominating.

Proposition 3.4 and Theorem 3.5 imply that no property between \(S_1(\Omega, \Omega)\) and \(\text{U}_{\text{fin}}(\mathcal{O}, \Omega)\) (inclusive) is provably additive. Surprisingly, this was only observed in [4].

\(^{3}\)Indeed, in [28] Scheepers points out that Proposition 3.4 implies that no class between \(S_1(\Omega, \Omega)\) and \(\text{S}_{\text{fin}}(\Omega, \Omega)\) is provably additive. The missing ingredient to upgrade to \(\text{U}_{\text{fin}}(\mathcal{O}, \Omega)\) was Theorem 3.5.
Corollary 3.6 (Bartoszyński-Shelah-Tsaban [4]). Assume that \( \text{cov}(\mathcal{M}) = \kappa \). Then there exist \( \kappa \)-Luzin subsets \( L_0 \) and \( L_1 \) of \( \mathbb{Z}^\mathbb{N} \) satisfying \( S_1(\Omega, \Omega) \), such that the \( \kappa \)-Luzin set \( L_0 \cup L_1 \) is 2-dominating. In particular, \( L_0 \cup L_1 \) does not satisfy \( \bigcup_{f \in \mathcal{O}} \{ f : f \in L_0 \cup L_1 \} \).

**Proof.** Let \( L_0, L_1 \) be as in Proposition 3.4. As \( L_0 + L_1 = \mathbb{Z}^\mathbb{N} \) and in general \( (f + g)/2 \leq \max\{f, g\} \) for all \( f, g \in \mathbb{Z}^\mathbb{N} \), we have that \( L_0 \cup L_1 \) is 2-dominating. By Theorem 3.5 the continuous image \( \{ |f| : f \in L_0 \cup L_1 \} \) of \( L_0 \cup L_1 \) does not satisfy \( \bigcup_{f \in \mathcal{O}} \{ f : f \in L_0 \cup L_1 \} \). \( \square \)

We now treat the Borel case.

Theorem 3.7 (Bartoszyński-Shelah-Tsaban [4]). Assume that \( \text{cov}(\mathcal{M}) = \kappa \). Then there exist \( \kappa \)-Luzin subsets \( L_1 \) and \( L_2 \) of \( \mathbb{Z}^\mathbb{N} \) satisfying \( S_1(\mathcal{B}_1, \mathcal{B}_2) \), such that for each \( g \in \mathbb{Z}^\mathbb{N} \) there are \( f_0 \in L_0, f_1 \in L_1 \) satisfying \( f_1(n) + f_2(n) = g(n) \) for all but finitely many \( n \).

In particular, the \( \kappa \)-Luzin set \( L_0 \cup L_1 \) is 2-dominating, and consequently does not satisfy \( \bigcup_{f \in \mathcal{O}} \{ f : f \in L_0 \cup L_1 \} \).

**Proof.** We follow the proof steps of Proposition 3.4. The major problem is that here the sets \( G_i^{F,\beta} \) need not be comeager. In order to overcome this, we will consider only \( \omega \)-covers where these sets are guaranteed to be comeager, and make sure that it is enough to restrict attention to this special sort of \( \omega \)-covers. The following definition is essentially due to [29], but with a small twist that makes it work.

Definition 3.8 ([4]). A cover \( \mathcal{U} \) of \( X \) is \( \omega \)-fat if for each finite \( F \subseteq X \) and each finite family \( \mathcal{F} \) of nonempty open sets, there exists \( U \in \mathcal{U} \) such that \( F \subseteq U \) and for each \( O \in \mathcal{F} \), \( U \cap O \) is not meager. (Thus each \( \omega \)-fat cover is an \( \omega \)-cover.) Let \( \mathcal{B}^\text{fat}_{\Omega} \) denote the collection of countable \( \omega \)-fat Borel covers of \( X \).

Lemma 3.9 ([4]). Assume that \( \mathcal{U} \) is a countable collection of Borel sets of reals. Then \( \mathcal{U} \) is comeager if, and only if, for each nonempty basic open set \( O \) there exists \( U \in \mathcal{U} \) such that \( U \cap O \) is not meager.

**Proof.** (\( \Rightarrow \)) Assume that \( \mathcal{U} \) is a nonempty basic open set. Then \( \bigcup_{U \cap O} \{ U \cap O : U \in \mathcal{U} \} \) is a countable union which is not meager. Thus there exists \( U \in \mathcal{U} \) such that \( U \cap O \) is not meager.

(\( \Leftarrow \)) Set \( B = \bigcup_{U \cap O} \). As \( B \) is Borel, it has the Baire property. Let \( O \) be an open set and \( M \) be a meager set such that \( B = (O \setminus M) \cup (M \setminus O) \). For each basic open set \( G \), \( B \cap G \) is not meager, thus \( O \cap G \) is not meager as well. Thus, \( O \) is open dense. As \( O \setminus M \subseteq B \), we have that \( \mathbb{R} \setminus B \subseteq (\mathbb{R} \setminus O) \cup M \) is meager. \( \square \)

Corollary 3.10 ([4]). Assume that \( \mathcal{U} \) is an \( \omega \)-fat cover of some set \( X \). Then:
(1) For each finite $F \subseteq X$ and finite family $\mathcal{F}$ of nonempty basic open sets, the set
\[ \bigcup \{ U \in \mathcal{U} : F \subseteq U \text{ and for each } O \in \mathcal{F}, U \cap O \notin \mathcal{M} \} \]
is comeager.

(2) For each element $x$ in the intersection of all sets of this form, $\mathcal{U}$ is an $\omega$-fat cover of $X \cup \{ x \}$.

Proof. Write $V_{F, \mathcal{F}} = \{ U \in \mathcal{U} : F \subseteq U \text{ and for each } O \in \mathcal{F}, U \cap O \notin \mathcal{M} \}$.

(1) Assume that $G$ is a nonempty open set. As $\mathcal{U}$ is $\omega$-fat and the family $\mathcal{F} \cup \{ G \}$ is finite, there exists $U \in V_{F, \mathcal{F}}$ such that $U \cap G$ is not meager. By Lemma 3.9, $\bigcup V_{F, \mathcal{F}}$ is comeager.

(2) Assume that $F$ is a finite subset of $X \cup \{ x \}$ and $\mathcal{F}$ is a finite family of nonempty basic open sets. As $x \in \bigcup V_{F, \mathcal{F}} \setminus \{ x \}$, there exists $U \in \mathcal{U}$ such that $x \in U$, $F \setminus \{ x \} \subseteq U$ (thus $F \subseteq U$), and for each $O \in \mathcal{F}$, $U \cap O$ is not meager. □

Lemma 3.11 ([4]). If $|X| < \text{cov}(\mathcal{M})$, then $X$ satisfies $S_1(\mathcal{B}_{\Omega}^{\text{fat}}, \mathcal{B}_{\Omega}^{\text{fat}})$.

Proof. Assume that $|X| < \text{cov}(\mathcal{M})$, and let $\{ U_n \}_{n \in \mathbb{N}}$ be a sequence of countable Borel $\omega$-fat covers of $X$. Enumerate each cover $\mathcal{U}_n$ by $\{ U_k^n \}_{k \in \mathbb{N}}$. Let $\{ A_n \}_{n \in \mathbb{N}}$ be a partition of $\mathbb{N}$ into infinitely many infinite sets. For each $m$, let $a_m \in \mathbb{N}^\mathbb{N}$ be an increasing enumeration of $A_m$. Let $\{ \mathcal{F}_n \}_{n \in \mathbb{N}}$ be an enumeration of all finite families of nonempty basic open sets.

For each finite subset $F$ of $X$ and each $m$ define a function $\Psi_F^m \in \mathbb{N}^{\mathbb{N}}$ by
\[ \Psi_F^m(n) = \min \{ k : F \subseteq U_k^{a_m(n)} \text{ and for each } O \in \mathcal{F}_m, U_k^{a_m(n)} \cap O \notin \mathcal{M} \} \]
Since there are less than $\text{cov}(\mathcal{M})$ many functions $\Psi_F^m$, there exists by [1] a function $f \in \mathbb{N}^{\mathbb{N}}$ such that for each $m$ and $F$, $\Psi_F^m(n) = f(n)$ for infinitely many $n$. Consequently, $\mathcal{V} = \{ U_{f(n)}^{a_m(n)} : m, n \in \mathbb{N} \}$ is an $\omega$-fat cover of $X$. □

The following lemma justifies our focusing on $\omega$-fat covers.

Lemma 3.12 ([4]). Assume that $L$ is a set of reals such that for each nonempty basic open set $O$, $L \cap O$ is not meager. Then every countable Borel $\omega$-cover $\mathcal{U}$ of $L$ is an $\omega$-fat cover of $L$.

Proof. Assume that $\mathcal{U}$ is a countable collection of Borel sets which is not an $\omega$-fat cover of $L$. Then there exist a finite set $F \subseteq L$ and
nonempty open sets \(O_1, \ldots, O_k\) such that for each \(U \in \mathcal{U}\) containing \(F, U \cap O_i\) is meager for some \(i\). For each \(i = 1, \ldots, k\) let
\[
M_i = \bigcup \{U \in \mathcal{U} : F \subseteq U \text{ and } U \cap O_i \in \mathcal{M}\}.
\]
Then \(M_i \cap O_i\) is meager, thus there exists \(x_i \in (L \cap O_i) \setminus M_i\). Then \(F \cup \{x_1, \ldots, x_k\}\) is not covered by any \(U \in \mathcal{U}\).

Let \(Z^N = \{y_\alpha : \alpha < c\}\), \(\{M_\alpha : \alpha < c\}\) be all \(F_\alpha\) meager subsets of \(Z^N\), and \(\{U_\alpha^0\}_{n \in N} : \alpha < c\) be all sequences of countable families of Borel sets. Let \(\{O_k : k \in N\}\) and \(\{F_m : m \in N\}\) be all nonempty basic open sets and all finite families of nonempty basic open sets, respectively, in \(Z^N\).

We construct \(L_i = \{x_\beta^i : \beta < c\}, i = 0, 1\), by induction on \(\alpha < c\) as follows. At stage \(\alpha \geq 0\) set \(X_\alpha^i = \{x_\beta^i : \beta < \alpha\}\) and consider the sequence \(\{U_\alpha^0\}_{n \in N}\). Say that \(\alpha\) is \(i\)-good if for each \(n\) \(U_\alpha^0\) is an \(\omega\)-fat cover of \(X_\alpha^i\). In this case, by Lemma 3.11 there exist elements \(U_n^{i,\beta} \in \mathcal{U}_\beta\) such that \(\{U_n^{i,\beta}\}_{n \in N}\) is an \(\omega\)-fat cover of \(X_\alpha^i\). We make the inductive hypothesis that for each \(i\)-good \(\beta < \alpha, \{U_n^{i,\beta}\}_{n \in N}\) is an \(\omega\)-fat cover of \(X_\alpha^i\). For each finite \(F \subseteq X_\alpha^i, i\)-good \(\beta \leq \alpha\), and \(m\) define
\[
G_{i,\beta,m} = \bigcup \{U_n^{i,\beta} : F \subseteq U_n^{i,\beta} \text{ and for each } O \in F_m, U_n^{i,\beta} \cap O \notin \mathcal{M}\}.
\]
By Corollary 3.10(1), \(G_{i,\beta,m}\) is comeager. Set
\[
Y_\alpha = \bigcup_{\beta < \alpha} M_\beta \cup \bigcup_{m \in N, F \subseteq X_\alpha^i \text{ Finite}} \left\{Z^N \setminus G_{i,\beta,m}^{F,\beta,m} : i < 2, \beta \leq \alpha \text{ i-good, } m \in N\right\}.
\]
and \(Y_\alpha^* = \{x \in Z^N : (\exists y_\in Y_\alpha\) \(x =^* y\)\} (\text{where } x =^* y\text{ means that } x(n) = y(n)\text{ for all but finitely many } n).\) Then \(Y_\alpha^*\) is a union of less than \(\text{cov}(\mathcal{M})\) many meager sets. Use Lemma 3.3 to pick \(x_0^\alpha, x_1^\alpha \in Z^N \setminus Y_\alpha^*\) such that \(x_0^\alpha + x_1^\alpha = y_\alpha\). Let \(k = \alpha \mod \omega\), and change a finite initial segment of \(x_0^\alpha\) and \(x_1^\alpha\) so that they both become members of \(O_k\). Then \(x_0^\alpha, x_1^\alpha \in O_k \setminus Y_\alpha, x_0^\alpha + x_1^\alpha =^* y_\alpha\). By Corollary 3.10(2), the inductive hypothesis is preserved.

Thus each \(L_i\) satisfies \(S_1(\mathcal{B}_0, \mathcal{B}_0)\) and its intersection with each nonempty basic open set has size \(c\). By Lemma 3.12 \(\mathcal{B}_0 = \mathcal{B}_0, \text{ for } L_i,\) finally, \(L_0 + L_1\) is dominating, so \(L_0 \cup L_1\) is 2-dominating.

Thus, no class between \(S_1(\mathcal{B}_0, \mathcal{B}_0)\) and \(\mathcal{U}_{\text{fin}}(\mathcal{O}, \Omega)\) (inclusive) is provably additive.

Remark 3.13. As \(\text{non}(\mathcal{U}_{\text{fin}}(\mathcal{O}, \Omega)) = \mathcal{d}\), a natural question is whether the method of Proposition 3.3 can be generalized to work for \(\mathcal{U}_{\text{fin}}(\mathcal{O}, \Omega)\) under the weaker assumption \(\mathcal{d} = c\). By the forthcoming Theorem 4.2 such a trial is doomed to fail, since \(u < g\) implies that \(g = \mathcal{d} = c\).
3.2. **On splitting properties.** It is well known that nonprincipal ultrafilters on \( \mathbb{N} \) do not have the Baire property, and in particular are nonmeager \[^3\]. We can prove more than that.

**Lemma 3.14** (Shelah \[^33\]). Assume that \( U \) is a nonprincipal ultrafilter on \( \mathbb{N} \) and that \( M \subseteq [\mathbb{N}]^{\aleph_0} \) is meager. Then \( U \setminus M \) is a subbase for \( U \). In fact, for each \( a \in U \) there exist \( a_0, a_1 \in U \setminus M \) such that \( a_0 \cap a_1 \subseteq a \).

**Proof.** Recall that \( [\mathbb{N}]^{\aleph_0} \) is a subspace of \( P(\mathbb{N}) \) whose topology is defined by its identification with \( \{0,1\}^\mathbb{N} \). It is well known \[^3 \[8\] that for each meager subset \( M \) of \( \{0,1\}^\mathbb{N} \) there exist \( x \in \{0,1\}^\mathbb{N} \) and an increasing \( h \in \mathbb{N}^\mathbb{N} \) such that

\[
M \subseteq \{ y \in \{0,1\}^\mathbb{N} : (\forall n \in \mathbb{N}) \ y \cap [h(n), h(n+1)] \neq \emptyset \}.
\]

(The set on the right hand side is also meager.) Translating this to the language of \([\mathbb{N}]^{\aleph_0}\), we get that for each \( n \) there exist disjoint sets \( I_0^n \) and \( I_1^n \) satisfying \( \bigcup I_0^n \cup I_1^n = [h(n), h(n+1)) \), such that

\[
M \subseteq \{ y \in [\mathbb{N}]^{\aleph_0} : (\forall n \in \mathbb{N}) \ y \cap I_0^n \neq \emptyset \text{ or } I_1^n \not\subseteq y \}.
\]

Assume that the sets \( I_0^n, I_1^n \), \( n \in \mathbb{N} \), are chosen as in \( \text{(1)} \). Let \( a \) be an infinite co-infinite subset of \( \mathbb{N} \). Then either

\[
x = \bigcup_{n \in a} [h(n), h(n+1)) \notin U,
\]

or else \( x = \bigcup_{n \in a \cap \mathbb{N}} [h(n), h(n+1)) \notin U \). We may assume that the former case holds. Split \( a \) into two disjoint infinite sets \( a_1 \) and \( a_2 \). Then \( x_i = \bigcup_{n \in a_i} [h(n), h(n+1)) \notin U \) \((i = 0, 1)\).

Assume that \( b \in U \). Then \( \tilde{b} = b \setminus x = b \cap (\mathbb{N} \setminus x) \in U \). Define sets \( y_1, y_2 \subseteq U \setminus M \) as follows.

\[
y_1 = \tilde{b} \cup \bigcup_{n \in a_2} I_1^n,
\]

\[
y_2 = \tilde{b} \cup \bigcup_{n \in a_1} I_0^n.
\]

By \( \text{(1)} \), \( y_1, y_2 \notin M \). As \( y_1, y_2 \supseteq \tilde{b} \), \( y_1, y_2 \in U \). Now, \( y_1 \cap y_2 = \tilde{b} \subseteq b \).

**Theorem 3.15** (Tsaban \[^33\]). Assume that \( \text{add}(\mathcal{M}) = \mathfrak{c} \). Then there exist two \( c \)-Luzin sets \( L_0 \) and \( L_1 \) such that:

1. \( L_0, L_1 \) satisfy \( S_1(\mathcal{B}^c, \mathcal{B}_\Omega) \),
2. \( L = L_0 \cup L_1 \) satisfies \( \text{Split}(\mathcal{B}_\Lambda, \mathcal{B}_\Lambda) \); and
3. \( L = L_0 \cup L_1 \) does not satisfy \( \text{Split}(\Omega, \Omega) \).

**Proof.** We follow the footsteps of the proof of Theorem \[3.7\]. Let \( U = \{ a_{\alpha} : \alpha < c \} \) be a nonprincipal ultrafilter on \( \mathbb{N} \). Let \( \{ M_{\alpha} : \alpha < c \} \) enumerate all \( F_{\alpha} \) meager sets in \( [\mathbb{N}]^{\aleph_0} \), and \( \{ \mu_n^\alpha : n \in \mathbb{N} : \alpha < c \} \) enumerate all countable sequences of countable families of Borel sets in \( [\mathbb{N}]^{\aleph_0} \). Let \( \{ O_i : i \in \mathbb{N} \} \) and \( \{ F_i : i \in \mathbb{N} \} \) enumerate all nonempty basic
open sets and finite families of nonempty basic open sets, respectively, in $[N]^{\aleph_0}$.

We construct $L_i = \{a^i_\beta : \beta < \mathfrak{c}\}$, $i = 0, 1$, by induction on $\alpha < \mathfrak{c}$ as follows. At stage $\alpha \geq 0$ set $X_\alpha = \{a^\alpha_\beta : \beta < \alpha\}$ and consider the sequence $\{U^\alpha_n\}_{n \in \mathbb{N}}$. Say that $\alpha$ is $i$-good if for each $n U^\alpha_n$ is an $\omega$-fat cover of $X^\alpha_n$. In this case, by the above remarks there exist elements $U^\alpha_n,i \in U^\alpha_n$ such that $\{U^\alpha_n,i\}_{n \in \mathbb{N}}$ is an $\omega$-fat cover of $X^\alpha_n$. We make the inductive hypothesis that for each $i$-good $\beta < \alpha$, $\{U_\beta^\alpha,i\}_{n \in \mathbb{N}}$ is an $\omega$-fat cover of $X^\alpha_i$. For each finite $F \subseteq X^\alpha_i$, $i$-good $\beta \leq \alpha$, and $m$ define

$$G^{F,\beta,m}_i = \bigcup \{U^\beta_n,i : F \subseteq U^\beta_n,i \text{ and } (\forall O \in F_m) U^\beta_n,i \cap O \notin \mathcal{M}\}.$$ 

By the inductive hypothesis, $G^{F,\beta,m}_i$ is comeager. Set

$$Y_\alpha = \bigcup_{\beta < \alpha} M_\beta \cup \left\{[N]^{\aleph_0} \setminus G^{F,\beta,m}_i : i < 2, \beta \leq \alpha \text{ i-good}, m \in \mathbb{N}, F \subseteq X^\alpha_i \text{ Finite} \right\},$$

and $Y_\alpha^* = \{x \in [N]^{\aleph_0} : (\exists y \in Y_\alpha) x =^* y\}$. (Here $x =^* y$ means that $x \subseteq y$ and $y \subseteq^* x$.) $Y_\alpha^*$ is a union of less than $\text{add}(\mathcal{M})$ many meager sets, and is therefore meager. Use Lemma 3.14 to pick $a^0_\alpha, a^1_\alpha \in U \setminus Y_\alpha^*$ such that $a^0_\alpha \cap a^1_\alpha \subseteq^* a_\alpha$. Let $k = \alpha \bmod \omega$, and change finitely many elements of $a^0_\alpha$ and $a^1_\alpha$ so that they both become members of $O_k$. Then $a^0_\alpha, a^1_\alpha \in (U \cap O_k) \setminus Y_\alpha$, and $a^0_\alpha \cap a^1_\alpha \subseteq^* a_\alpha$. Observe that the inductive hypothesis remains true for $\alpha$. This completes the construction.

Clearly $L_0$ and $L_1$ are $\mathfrak{c}$-Luzin sets and $L_0 \cup L_1$ is a subbase for $U$. We made sure that for each nonempty basic open set $G$, $|L_0 \cap G| = |L_1 \cap G| = \mathfrak{c}$, thus $B_\Omega = B_\Omega^{\text{fat}}$ for $L_0$ and $L_1$. By the construction, $L_0, L_1 \in \mathcal{S}_1(B_\Omega, B_\Omega^{\text{fat}})$.

As we assume that $\text{add}(\mathcal{M}) = \mathfrak{c}$, every $\mathfrak{c}$-Luzin set (in particular, $L_0 \cup L_1$) satisfies $\mathcal{S}_1(B, B)$ [20], and therefore also $\text{Split}(B_\lambda, B_\lambda)$.

**Lemma 3.16** (Just-Miller-Scheepers-Szeptycki [21]). If there is a continuous image of $X$ in $[N]^{\aleph_0}$ that is a subbase for a nonprincipal ultrafilter on $\mathbb{N}$, then $X$ does not satisfy $\text{Split}(\Omega, \Omega)$. \hfill $\square$

As $L_0 \cup L_1$ is a subbase for a nonprincipal ultrafilter on $\mathbb{N}$, it does not satisfy $\text{Split}(\Omega, \Omega)$. \hfill $\square$

It follows that no property between $\mathcal{S}_1(B_\Omega, B_\Omega)$ and $\text{Split}(\Omega, \Omega)$ is provably additive.

4. Consistently positive results

4.1. On the Scheepers diagram.
Theorem 4.1 (folklore). It is consistent that all classes between $\mathcal{S}_1(\Omega, \Gamma)$ and $\mathcal{S}_1(\mathcal{O}, \mathcal{O})$ (inclusive) are $\sigma$-additive.

Proof. As $\mathcal{S}_1(\mathcal{O}, \mathcal{O})$ implies strong measure zero, Borel’s Conjecture (which asserts that every strong measure zero set is countable) implies that all elements of $\mathcal{S}_1(\mathcal{O}, \mathcal{O})$ are countable, and thus all classes below $\mathcal{S}_1(\mathcal{O}, \mathcal{O})$ are $\sigma$-additive. Borel’s Conjecture was proved consistent by Laver [23]. □

A variant of Borel’s Conjecture for $U_{\text{fin}}(\mathcal{O}, \Omega)$ is false [21, 27, 5, 34]. However, we have the following.

Theorem 4.2 (Bartoszyński-Shelah-Tsaban [4], Zsomskyy [38, 36]). If $u < g$, then $\text{add}(U_{\text{fin}}(\mathcal{O}, \Omega)) = \text{add}(\mathcal{S}_1(\mathcal{B}_\Gamma, \mathcal{B}_\Omega)) = c$.

Proof. In [38, 36] it is proved that $u < g$ implies that $U_{\text{fin}}(\mathcal{O}, \Omega) = \mathcal{S}_{\text{fin}}(\mathcal{O}, \mathcal{O})$, and the same assertion holds in the Borel case. The theorem follows from Corollary 2.9 together with the fact that $u < g$ implies that $g = c$ [8]. □

In the remainder of this section we will show that $\sigma$-additivity of $U_{\text{fin}}(\mathcal{O}, \Omega)$ (and $\mathcal{S}_1(\mathcal{B}_\Gamma, \mathcal{B}_\Omega)$) actually follow from the weaker axiom NCF, and that a suitable combinatorial version of this assertion actually gives a characterization of NCF.

In Theorem 3.5, $\mathbb{N}_N$ can be replaced by $\mathbb{N}_N^\mathbb{N}$ – the (strictly) increasing elements of $\mathbb{N}^\mathbb{N}$. To see this, note that the function $\Phi : \mathbb{N}^\mathbb{N} \to \mathbb{N}_N^\mathbb{N}$ defined by

$$\Phi(f)(n) = n + f(0) + f(1) + \ldots + f(n)$$

is a homeomorphism which preserves finite-dominance in both directions.

We now consider the purely combinatorial counterpart of the question whether $U_{\text{fin}}(\mathcal{O}, \Omega)$ is additive. Let $\mathcal{D}_{\text{fin}}$ denote the collection of subsets of $\mathbb{N}_N^\mathbb{N}$ which are not finitely-dominating. By the previous comment,

$$\text{add}(\mathcal{D}_{\text{fin}}) \leq \text{add}(U_{\text{fin}}(\mathcal{O}, \Omega)) \leq \text{add}(\mathcal{S}_1(\mathcal{B}_\Gamma, \mathcal{B}_\Omega)).$$

Recall that for an increasing $h \in \mathbb{N}_N^\mathbb{N}$ and a filter $\mathcal{F} \subseteq [\mathbb{N}]^{\mathbb{N}_0}$,

$$\mathcal{F}/h = \{a/h : a \in \mathcal{F}\} = \left\{a : \bigcup_{n \in a} [h(n), h(n+1)) \in \mathcal{F}\right\}.$$

(The first equality is the definition; the second an easy fact.) If $\mathcal{F}$ is an ultrafilter, then so is $\mathcal{F}/h$. We say that filters $\mathcal{F}_1$ and $\mathcal{F}_2$ on $\mathbb{N}$ are compatible in the Rudin-Keisler order (or, in short, Rudin-Keisler compatible) if there is an increasing $h \in \mathbb{N}_N^\mathbb{N}$ such that $\mathcal{F}_1/h \cup \mathcal{F}_2/h$
satisfies the finite intersection property (that is, it is a filter base). If \( \mathcal{F}_1, \mathcal{F}_2 \) are Rudin-Keisler compatible ultrafilters, then there is an increasing \( h \in \mathbb{N}^\mathbb{N} \) such that \( \mathcal{F}_1/h = \mathcal{F}_2/h \).

**Definition 4.3.** NCF (near coherence of filters) is the assertion that every two nonprincipal ultrafilters on \( \mathbb{N} \) are Rudin-Keisler compatible.

NCF is independent of ZFC \([10, 11]\), and has many equivalent forms and implications (e.g., \([6, 7]\)).

In the sequel, we often use the following convenient notation for \( f, g \in \mathbb{N}^\mathbb{N} \):

\[
[f \leq g] = \{ n : f(n) \leq g(n) \}.
\]

**Theorem 4.4** (Bartoszyński-Shelah-Tsaban \([4]\)). NCF holds if, and only if, \( \mathcal{D}_{\text{fin}} \) is additive.

**Proof.** \((\Rightarrow)\) Assume that \( Y_1, Y_2 \in \mathcal{D}_{\text{fin}} \). We may assume that all elements of \( Y_1 \) and \( Y_2 \) are strictly increasing and that \( Y_1 \) and \( Y_2 \) are closed under finite maxima. Thus, it suffices to show that

\[
\{ \max\{ f_1, f_2 \} : f_1 \in Y_1, f_2 \in Y_2 \}
\]

is not dominating. For each \( i = 1, 2 \), do the following: Choose an increasing \( g_i \in \mathbb{N}^\mathbb{N} \) witnessing that \( Y_i \) is not dominating. The set \( \{ [f \leq g] : f \in Y_i \} \) has the finite intersection property. Extend it to a nonprincipal ultrafilter \( \mathcal{F}_i \).

Fix an increasing \( h \in \mathbb{N}^\mathbb{N} \) such that \( \mathcal{F}_i/h \cup \mathcal{F}_2/h \) has the finite intersection property. Define \( g \in \mathbb{N}^\mathbb{N} \) by \( g(n) = \max\{ g_1(h(n+1)), g_2(h(n+1)) \} \) for each \( n \). Given \( f_1 \in Y_1, f_2 \in Y_2 \), let \( a \) be the infinite set \( [f_1 \leq g_1]/h \cap [f_2 \leq g_2]/h \). For each \( n \in a \) and each \( i = 1, 2 \), there is \( k \in [h(n), h(n+1)) \) such that \( f_i(k) \leq g_i(k) \). Thus,

\[
f_i(n) \leq f_i(h(n)) \leq f_i(k) \leq g_i(k) \leq g_i(h(n+1)) \leq g(n),
\]

thus \( \max\{ f_1(n), f_2(n) \} \leq g(n) \) for all \( n \in a \).

\((\Leftarrow)\) We will use the following.

**Lemma 4.5** \((\mathbb{I})\). If NCF fails, then there exist ultrafilters \( \mathcal{F}_1 \) and \( \mathcal{F}_2 \) such that for each increasing \( h \in \mathbb{N}^\mathbb{N} \) there exist \( a_1 \in \mathcal{F}_1/h \) and \( a_2 \in \mathcal{F}_2/h \) such that for all \( n \in a_1 \) and \( m \in a_2, |n - m| > 1 \).

**Proof.** Assume that \( \mathcal{F}_1 \) and \( \mathcal{F}_2 \) are Rudin-Keisler incompatible nonprincipal ultrafilters and let \( h \) be an increasing element of \( \mathbb{N}^\mathbb{N} \). Define increasing \( f_0, f_1 \in \mathbb{N}^\mathbb{N} \) by

\[
\begin{align*}
f_0(n) &= h(2n) \\
f_1(n) &= h(2n + 1)
\end{align*}
\]
Then there exist
\[ X_1 \in F_1/f_0 \quad X_2 \in F_2/f_0 \]
\[ Y_1 \in F_1/f_1 \quad Y_2 \in F_2/f_1 \]
such that the sets \( X_1 \cap X_2 = Y_1 \cap Y_2 = \emptyset \)\(^4\) For \( i = 1, 2 \) let
\[ \tilde{X}_i = 2 \cdot X_i \cup (2 \cdot X_i + 1) \]
\[ \tilde{Y}_i = (2 \cdot Y_i + 1) \cup (2 \cdot Y_i + 2) \]
Observe that \( \tilde{X}_1 \cap \tilde{X}_2 = \tilde{Y}_1 \cap \tilde{Y}_2 = \emptyset \) either. Now,
\[ \bigcup_{n \in X_i} [f_0(n), f_0(n+1)) = \bigcup_{n \in X_i} [h(n), h(n+1)) \]
\[ \bigcup_{n \in Y_i} [f_1(n), f_1(n+1)) = \bigcup_{n \in Y_i} [h(n), h(n+1)) \]
therefore \( \tilde{X}_i, \tilde{Y}_i \in F_i/h \), thus \( a_i = \tilde{X}_i \cap \tilde{Y}_i \in F_i/h \). If \( n \in a_1 \) is even, then \( n, n+1 \in \tilde{X}_1 \), and \( n-1, n \in \tilde{Y}_1 \). Thus, if \( n \) is large enough, then \( n, n+1 \notin X_2 \), and \( n-1, n \notin Y_2 \), therefore \( n-1, n+1 \notin a_2 \). The case that \( n \in a_1 \) is odd is similar. \( \square \)

For a filter \( F \) and an increasing \( g \in \mathbb{N}^\mathbb{N} \), define
\[ Y_{F,g} = \{ f \in \mathbb{N}^\mathbb{N} : [f \leq g] \in F \}. \]
Then \( Y_{F,g} \in \mathcal{D}_{\text{fin}} \). It therefore suffices to prove the following.

**Lemma 4.6.** If \( F_1 \) and \( F_2 \) are as in Lemma 4.5, and \( g(n) \geq 2n \) for each \( n \), then \( Y_{F_1,g} \cup Y_{F_2,g} \) is 2-dominating.

**Proof.** Let \( f \in \mathbb{N}^\mathbb{N} \) be any increasing function. Define by induction
\[
\begin{align*}
h(0) &= 0 \\
h(n+1) &= f(h(n)) + 1
\end{align*}
\]
By the assumption, there exist \( a_1 \in F_1/h \) and \( a_2 \in F_2/h \) such that for each \( n \in a_1 \) and \( m \in a_2 \), \( |n-m| > 1 \).

Fix \( i < 2 \). For each \( n \), define
\[
f_i(n) = \begin{cases} 
  f(h(k-1)) + n - h(k-1) & n \in [h(k), h(k+1)) \text{ for } k \in a_i \\
  f(h(k)) + n - h(k) & n \in [h(k), h(k+1)) \text{ where } k \notin a_i, k + 1 \in a_i \\
  f(n) & \text{otherwise}
\end{cases}
\]
It is not difficult to verify that \( f_i \) is increasing.

\(^4\)Since nonprincipal filters are closed under finite modifications, we can shrink the elements to turn the finite intersection into an empty intersection.
For each \( k \in a_i \) and \( n \in [h(k), h(k+1)) \),
\[
f_i(n) = f(h(k-1)) + n - h(k-1) \leq h(k) + n - h(k-1) \leq h(k) + n \leq 2n \leq g(n).
\]
Therefore \( f_i \in Y_{F_1,g} \).

For each \( n \) let \( k \) be such that \( n \in [h(k), h(k+1)) \). If \( n \) is large enough, then either \( k, k+1 \notin a_1 \), and therefore \( f_1(n) = f(n) \), or else \( k, k+1 \notin a_2 \), and therefore \( f_2(n) = f(n) \), that is, \( f(n) \leq \max\{ f_1(n), f_2(n) \} \).

This completes the proof of Theorem 4.4. \( \Box \)

Let \( \text{add}(D_{\text{fin}}, D) \) denote the minimal cardinality of a collection of members of \( D_{\text{fin}} \) whose union is dominating. It is immediate that \( b \leq \text{add}(D_{\text{fin}}, D) \).

**Lemma 4.7** (Blass [9]). \( \max\{ b, g \} \leq \text{add}(D_{\text{fin}}, D) \).

**Proof.** We need only prove that \( g \leq \text{add}(D_{\text{fin}}, D) \). Assume that \( \kappa < g \) and \( Y_\alpha \in D_{\text{fin}}, \alpha < \kappa \). We may assume each \( Y_\alpha \) is closed under pointwise maxima of its finite subsets. For each \( \alpha \), let \( g_\alpha \) be a witness for \( Y_\alpha \) not being dominating, and extend \( \{ [f \leq g_\alpha] : f \in Y_\alpha \} \) to a nonprincipal ultrafilter \( F_\alpha \) on \( \mathbb{N} \).

We will use the following “morphism”.

**Lemma 4.8** (Mildenberger [18, 19]). For each \( f \in \mathbb{N}^\omega \) and each ultrafilter \( U \),
\[
G_{U,f} = \{ a \in [\mathbb{N}]^{\aleph_0} : f \leq_U a^+ \}
\]
is groupwise dense.

**Proof.** Clearly, \( G_{U,f} \) is closed under taking almost subsets. Assume that \( \{ [h(n), h(n+1)) : n \in \omega \} \) is an interval partition of \( \omega \). By merging consecutive intervals we may assume that for each \( n \), and each \( k \in [h(n), h(n+1)) \), \( f(k) \leq h(n+2) \).

Since \( U \) is an ultrafilter, there exists \( \ell \in \{ 0, 1, 2 \} \) such that
\[
a_\ell = \bigcup_n [h(3n + \ell), h(3n + \ell + 1)) \in U
\]
Take \( a = a_{\ell+2 \mod 3} \). For each \( k \in a_\ell \), let \( n \) be such that \( k \in [h(3n + \ell), h(3n + \ell + 1)) \). Then \( f(k) \leq h(3n + \ell + 2) = a^+(k) \). Thus \( a \in G_{U,f} \).

Thus, we can take \( a \in \bigcap_{\alpha < \kappa} G_{U_\alpha,g_\alpha} \), and \( g = a^+ \) will witness that \( \bigcup_{\alpha < \kappa} Y_\alpha \) is not dominating. \( \Box \)

\(^5\)In fact we get equality here.
Theorem 4.9. If \( D_{\text{fin}} \) is additive (equivalently, NCF holds), then it is \( \text{add}(D_{\text{fin}}, \mathcal{D}) \)-additive and therefore \( \max\{b, g\} \)-additive. In particular, in this case it is \( \sigma \)-additive.

Proof. Assume that \( \kappa < \text{add}(D_{\text{fin}}, \mathcal{D}) \) and \( Y_\alpha \in D_{\text{fin}}, \alpha < \kappa \). We may assume that each \( Y_\alpha \) is closed under pointwise maxima of finite subsets, and that the family \( \{Y_\alpha : \alpha < \kappa\} \) is additive. It follows that

\[
\max_{\alpha < \kappa} \left( \bigcup_{\alpha < \kappa} Y_\alpha \right) = \bigcup_{\alpha < \kappa} Y_\alpha
\]

and is therefore not dominating. Thus, \( \bigcup_{\alpha < \kappa} Y_\alpha \in D_{\text{fin}} \).

The second assertion follows from Lemma 4.7. \( \square \)

Corollary 4.10. If NCF holds, then

\[
\max\{b, g\} \leq \text{add}(\mathcal{U}_{\text{fin}}(\mathcal{O}, \Omega)) \leq \text{add}(S_1(B_\Gamma, B_\Omega)) \leq \text{cf}(\mathcal{D}) = \mathcal{D}.\]

Recently, Banakh and Zdomskyy improved Theorem 4.9 and Corollary 4.10 by showing that NCF implies that \( \text{add}(D_{\text{fin}}) = \text{add}(\mathcal{U}_{\text{fin}}(\mathcal{O}, \Omega)) = \mathcal{D} \).

Problem 4.11. Is any of the classes \( S_{\text{fin}}(\Omega, \Omega), S_1(\Gamma, \Omega), \) and \( S_{\text{fin}}(\Gamma, \Omega) \) consistently additive?

For the Borel case there remains only one unsolved class.

Problem 4.12. Is \( S_{\text{fin}}(B_\Omega, B_\Omega) \) consistently additive?

4.2. On splitting properties.

Theorem 4.13 (Zsosmkyy [38, 36]). It is consistent that \( \text{add}(\text{Split}(\Lambda, \Lambda)) = \text{add}(\text{Split}(B_\Lambda, B_\Lambda)) = b = u \).

Proof. In [38, 36] it is proved that \( u < g \) implies that \( \text{Split}(\Lambda, \Lambda) = \mathcal{U}_{\text{fin}}(\mathcal{O}, \Gamma) \), and the same assertion holds in the Borel case. The theorem follows from Corollary 2.4 together with the fact that \( u < g \) implies that \( b = u \) [8]. \( \square \)

The last theorem implies that one cannot obtain a negative solution to Problem 2.20 in ZFC.

5. \( \tau \)-covers

\( \mathcal{U} \) is a \( \tau \)-cover of \( X \) if it is a large cover of \( X \) (that is, each member of \( X \) is contained in infinitely many members of the cover), and for all \( x, y \in X \), (at least) one of the sets \( \{U \in \mathcal{U} : x \in U, y \notin U\} \) and \( \{U \in \mathcal{U} : y \in U, x \notin U\} \) is finite. \( \tau \)-covers are motivated by the tower number \( t \) [30] and were incorporated into the framework of
selection principles in [31]. Every open \( \tau \)-cover of a set of reals contains a countable \( \tau \)-cover of that set [33]. Let \( T \) and \( B_T \) denote the collections of countable open and Borel \( \tau \)-covers of \( X \), respectively.

5.1. **On the Scheepers diagram.** Taking \( T \) into account and removing trivial properties and known equivalences, we obtain the diagram in Figure 2 [31, 20]. In this diagram too, the critical cardinality of each property appears below it. A similar diagram, with several additional equivalences, is available in the Borel case [31].

![Figure 2. The Scheepers diagram, enhanced with \( \tau \)-covers](image)

**Proposition 5.1.** \( S_1(T, \mathcal{O}) \) and \( S_1(B_T, \mathcal{B}) \) are \( \sigma \)-additive.

**Proof.** As in Proposition 2.1. \( \square \)

**Definition 5.2.** For each countable cover of \( X \) enumerated bijectively as \( \mathcal{U} = \{U_n\}_{n \in \mathbb{N}} \) we associate the Marczewski function \( h_\mathcal{U} : X \to P(\mathbb{N}) \), defined by \( h_\mathcal{U}(x) = \{n : x \in U_n\} \) for each \( x \in X \).

\( \mathcal{U} \) is a large cover of \( X \) if, and only if, \( h_\mathcal{U}[X] \subseteq [\mathbb{N}]^{\aleph_0} \). Let \( Y \subseteq [\mathbb{N}]^{\aleph_0} \). \( Y \) is centered if for each finite \( F \subseteq Y \), \( \cap F \) is infinite. A set \( a \in [\mathbb{N}]^{\aleph_0} \) is a pseudo-intersection of \( Y \) if \( a \subseteq^* y \) for all \( y \in Y \). \( Y \) is linearly quasiordered by \( \subseteq^* \) if for all \( y, z \in Y \), \( y \subseteq^* z \) or \( z \subseteq^* y \). Note that if \( Y \) has a pseudo-intersection or is linearly quasiordered by \( \subseteq^* \), then \( Y \) is centered.

**Lemma 5.3** (Tsaban [30]). Assume that \( \mathcal{U} \) is a countable large cover of \( X \).
(1) \( \mathcal{U} \) is an \( \omega \)-cover of \( X \) if, and only if, \( \mathcal{h}_{\mathcal{U}}[X] \) is centered.

(2) \( \mathcal{U} \) contains a \( \gamma \)-cover of \( X \) if, and only if, \( \mathcal{h}_{\mathcal{U}}[X] \) has a pseudo-intersection.

(3) \( \mathcal{U} \) is a \( \tau \)-cover of \( X \) if, and only if, \( \mathcal{h}_{\mathcal{U}}[X] \) is linearly quasiordered by \( \subseteq^* \).

For families \( \mathcal{B} \subseteq \mathcal{A} \) of covers of a space \( X \), define the property \( \mathcal{A} \) choose \( \mathcal{B} \) as follows.

\( \left( \mathcal{A} \mathcal{B} \right) \): For each \( U \in \mathcal{A} \), there is \( V \subseteq U \) such that \( V \in \mathcal{B} \).

This is a prototype for many classical topological notions, most notably compactness and being Lindelöf.

**Theorem 5.4** (Tsaban [31]). \( \text{add}((\mathcal{T}_\Gamma)) = \text{add}((\mathcal{B}_\Gamma)) = t \).

**Proof.** We prove the open case. Assume that \( \kappa < t \), and let \( X_\alpha, \alpha < \kappa \), be sets satisfying \( (T_\Gamma) \). Let \( \mathcal{U} \) be a countable open \( \tau \)-cover of \( X = \bigcup_{\alpha < \kappa} X_\alpha \). By Lemma 5.3, \( \mathcal{h}_{\mathcal{U}}[X] = \bigcup_{\alpha < \kappa} \mathcal{h}_{\mathcal{U}}[X_\alpha] \) is linearly quasiordered by \( \subseteq^* \). Since each \( X_\alpha \) satisfies \( (T_\Gamma) \), for each \( \alpha \) \( \mathcal{U} \) contains a \( \gamma \)-cover of \( X_\alpha \), that is, \( \mathcal{h}_{\mathcal{U}}[X_\alpha] \) has a pseudo-intersection.

**Lemma 5.5** (Tsaban [30]). Assume that \( Y \subseteq [\mathbb{N}]^{\aleph_0} \) is linearly quasiordered by \( \subseteq^* \), and for some \( \kappa < t \), \( Y = \bigcup_{\alpha < \kappa} Y_\alpha \) where each \( Y_\alpha \) has a pseudo-intersection. Then \( Y \) has a pseudo-intersection.

**Proof.** If for each \( \alpha < \kappa \) \( Y_\alpha \) has a pseudo-intersection \( y_\alpha \in Y_\alpha \), then a pseudo-intersection of \( \{y_\alpha : \alpha < \kappa\} \) is also a pseudo-intersection of \( Y \). Otherwise, there exists \( \alpha < \kappa \) such that \( Y_\alpha \) has no pseudo-intersection \( y \in Y \). That is, for all \( y \in Y \) there exists a \( z \in Y_\alpha \) such that \( y \not\subseteq^* z \); thus \( z \subseteq^* y \). Therefore, a pseudo-intersection of \( Y_\alpha \) is also a pseudo-intersection of \( Y \). \( \square \)

By Lemma 5.5, \( \mathcal{h}_{\mathcal{U}}[X] \) has a pseudo-intersection, that is, \( \mathcal{U} \) contains a \( \gamma \)-cover of \( X \). \( \square \)

**Corollary 5.6.** \( \text{add}(S_1(T, \Gamma)) = \text{add}(S_1(\mathcal{B}_T, \mathcal{B}_\Gamma)) = t \).

**Proof.** Note that

\[
S_1(T, \Gamma) = \left(\frac{T}{\Gamma}\right) \cap S_1(\Gamma, \Gamma).
\]

It follows that \( \text{add}(S_1(T, \Gamma)) \) is at least the minimum of the additivity numbers of \( (\frac{T}{\Gamma}) \) and \( S_1(\Gamma, \Gamma) \), which are \( t \) (Theorem 5.4) and \( \mathfrak{h} \) (Theorem 2.11), respectively. As \( t \leq \mathfrak{h} \) [8], \( \text{add}(S_1(T, \Gamma)) \geq t \). On the other hand, \( \text{add}(S_1(T, \Gamma)) \leq \text{non}(S_1(T, \Gamma)) = t \) (Figure 2).

In the Borel case use \( \text{add}(S_1(\mathcal{B}_T, \mathcal{B}_\Gamma)) = b \geq t \) (Theorem 2.4). \( \square \)

Note that \( S_{\text{fin}}(\Omega, T) \) implies \( (\frac{T}{\Gamma}) \).
Corollary 5.7 (Tsaban [31]). Assume the Continuum Hypothesis. Then no class between \( S_1(B_\Omega, B_T) \) and \( (\Omega_T) \) (inclusive) is additive.

Proof. By Theorem 3.1 there are sets \( A \) and \( B \) satisfying \( S_1(B_\Omega, B_T) \), such that \( A \cup B \) does not satisfy \( S_1(\Omega, \Gamma) \). Now,

\[
S_1(\Omega, \Gamma) = \left( \frac{\Omega}{T} \right) \cap S_1(T, \Gamma),
\]

and by Corollary 5.6 \( A \cup B \) satisfies \( S_1(T, \Gamma) \). Thus, \( A \cup B \) does not satisfy \( (\Omega_T) \).

\( \square \)

Problem 5.8. Is any of the properties \( S_1(T, T) \), \( S_{fin}(T, T) \), \( S_1(T, \Omega) \), \( S_{fin}(T, \Omega) \), and \( U_{fin}(O, T) \) (or any of their Borel versions) provably (or at least consistently) additive?

Zdomskyy [39] proved that consistently, \( U_{fin}(O, T) = U_{fin}(O, \Gamma) \), and in particular, \( U_{fin}(O, T) \) is consistently additive. Mildenberger, Shelah, and Tsaban [20] proved that \( S_1(T, T) \) is additive if, and only if, \( S_1(T, T) = S_1(T, \Gamma) \). We do not know whether the latter assertion is consistent.

Problem 5.9. Is any of the classes \( S_{fin}(\Omega, T) \), \( S_1(T, \Omega) \), and \( S_{fin}(T, \Omega) \) consistently additive?

5.2. On splitting properties. Here, taking \( T \) into account and removing trivialities and equivalences, we obtain the following diagram (in the open case, and a similar one in the Borel case) [33]:

\[
\begin{array}{c}
\text{Split}(\Lambda, \Lambda) \xrightarrow{r} \text{Split}(\Omega, \Lambda) \xrightarrow{u} \text{Split}(T, T) \xrightarrow{\text{undefined}} \\
\text{Split}(\Omega, \Omega) \xrightarrow{u} \\
\text{Split}(\Omega, T) \xrightarrow{p} \\
\text{Split}(\Omega, \Gamma) \xrightarrow{p} \text{Split}(T, \Gamma) \xrightarrow{t}
\end{array}
\]

We also have that \( \text{Split}(T, \Gamma) = \left( \frac{T}{\Gamma} \right) \) [33]. By Theorem 5.4, \( \text{add}(\text{Split}(T, \Gamma)) = t \).

Theorem 5.10 (Tsaban [33]). \( u \leq \text{add}(\text{Split}(T, T)) \).
Proof. A nonprincipal ultrafilter $U$ on $\mathbb{N}$ is called a simple $P$-point if there exists a base $B$ for $U$ such that $B$ is linearly quasiordered by $\subseteq^*$. We call such a base a simple $P$-point base.

**Lemma 5.11** ([33]). $X$ satisfies Split$(T, T)$ if, and only if, for each countable open $\tau$-cover $U$ of $X$, $h_U[X]$ is not a simple $P$-point base. \(\square\)

Thus, our theorem follows from the following Ramseyan property.

**Lemma 5.12** ([33]). Assume that $\lambda < u$ and $B = \bigcup_{\alpha < \lambda} B_\alpha$ is a simple $P$-point base. Then there exists $\alpha < \lambda$ such that $B_\alpha$ is a simple $P$-point base.

**Proof.** Assume that $B$ is a simple $P$-point base and $U$ is the simple $P$-point it generates. In particular, $B$ is linearly ordered by $\subseteq^*$. We will show that some $B_\alpha$ is a base for $U$. Assume otherwise. For each $\alpha < \lambda$ choose $a_\alpha \in U$ that witnesses that $B_\alpha$ is not a base for $U$, and $\tilde{a}_\alpha \in B$ such that $\tilde{a}_\alpha \subseteq^* a_\alpha$. As $B$ is linearly ordered by $\subseteq^*$, $\tilde{a}_\alpha$ is a pseudo-intersection of $B_\alpha$.

The cardinality of the linearly ordered set $Y = \{\tilde{a}_\alpha : \alpha < \lambda\}$ is smaller than $u$. Thus it is not a base for $U$ and we can find again an element $a \in F$ which is a pseudo-intersection of $Y$, and therefore of $B$; a contradiction. \(\square\)

This completes the proof of Theorem 5.10. \(\square\)

Consistently, there are no $P$-points [3]. By Lemma 5.11 in such a model Split$(T, T) = P(\mathbb{R})$ and therefore $\text{add}(\text{Split}(T, T))$ is undefined.

Note that Split$(\Omega, T)$ implies $\left(\begin{smallmatrix} \Omega \\ T \end{smallmatrix}\right)$, and since Split$(\mathcal{B}_\Omega, \mathcal{B}_T) = \left(\begin{smallmatrix} \mathcal{B}_\Omega \\ \mathcal{B}_T \end{smallmatrix}\right) = S_1(\mathcal{B}_\Omega, \mathcal{B}_T)$, we have by Corollary 5.7 that no class between Split$(\mathcal{B}_\Omega, \mathcal{B}_T)$ and Split$(\Omega, T)$ (inclusive) is provably additive.

Thus, Split$(\Omega, \Lambda)$, Split$(T, T)$, and Split$(T, \Gamma)$ are (provably) $\sigma$-additive, whereas $\text{Split}(\Omega, \Omega)$, $\text{Split}(\Omega, T)$, and $\text{Split}(\Omega, \Gamma)$ are not provably additive. The situation for Split$(\Lambda, \Lambda)$ is Problem 2.20.

**Problem 5.13.** Improve the lower bound or the upper bound in the inequality $\aleph_1 \leq \text{add}(\text{Split}(\Omega, \Lambda)) \leq \mathfrak{c}$.

**Problem 5.14.** Can the lower bound $u$ on $\text{add}(\text{Split}(T, T))$ be improved?

**Acknowledgements.** We thank Assaf Rinot and Lyubomyr Zdomskyy for reading the paper and making useful comments.
