ON NON-ABELIAN SYMPLECTIC CUTTING

JOHAN MARTENS AND MICHAEL THADDEUS

ABSTRACT. We discuss symplectic cutting for Hamiltonian actions of non-Abelian compact groups. By using a degeneration based on the Vinberg monoid we give, in good cases, a global quotient description of a surgery construction introduced by Woodward and Meinrenken, and show it can be interpreted in algebro-geometric terms. A key ingredient is the ‘universal cut’ of the cotangent bundle of the group itself, which is identified with a moduli space of framed bundles on chains of projective lines recently introduced by the authors.

1. Introduction

Since its introduction by Lerman in [Ler95], the technique of symplectic cutting has proven to be an elementary yet remarkably useful technique in symplectic geometry with diverse applications, e.g. [Hau98, LMTW98, LR01, Mar08]. Symplectic cutting starts from a symplectic manifold (or orbifold) \( M \) with a Hamiltonian action of a torus \( T \), and a (rational) polyhedral set \( P \) in \( \mathfrak{t}^* \); it returns a new Hamiltonian \( T \)-space \( M_P \) such that its image under the moment map is \( \mu_T(M_P) = \mu_T(M) \cap P \). Moreover the pre-images \( \mu_T^{-1}(\text{int}(P)) \) in \( M \) and \( M_P \) are \( T \)-equivariantly symplectomorphic.

The basic construction of the symplectic cut is as a global quotient (in [Ler95] only actions of a single \( U(1) \) were discussed, the natural generalization to cutting with arbitrary tori and polyhedral sets was given in [LMTW98]). One takes the Cartesian product \( M \times \mathbb{C}^n \), where \( n \) is the number of facets of \( P \), and then applies a symplectic reduction by the diagonal \( U(1)^n \) action:

\[
M_P := \left( M \times \mathbb{C}^n \right) / U(1)^n.
\]

From this definition it is clear what structures \( M_P \) obtains from \( M \): if the reduction is generic \( M_P \) will again be a symplectic orbifold with a Hamiltonian \( T \)-action, but it can inherit more. If \( M \) is Kähler and the \( T \)-action extends to one of \( T_\mathbb{C} \) then the cut space will be Kähler as well (though the symplectomorphism on \( \mu_T^{-1} \) will not be a Kähler isomorphism, see also [BGL02]);
in fact if \( M \) is (semi)projective the whole procedure can be understood as a GIT quotient in algebraic geometry \([EG98]\).

On a topological level, one can understand this construction also more locally, motivating the alternative name *equivariant symplectic surgery*. One takes the pre-image of \( P \) under the moment map \( \mu_T \), and on the pre-images of the facets of \( P \) collapses the circle-subgroups of \( T \) determined by the normal vectors to the facets:

\[
(2) \quad M_P \cong \mu^{-1}(P)/\sim = \bigsqcup_{P_I \subset P} \mu_T^{-1}(\text{int}(P_I))/T_I,
\]

where the \( P_I \subset P \) are the faces of \( P \), and \( T_I \) is the torus perpendicular to \( P_I \). In line with this local viewpoint Lerman remarks that symplectic cutting can be generalized to functions that are not globally moment maps of torus actions – this property is only needed in a pre-image of a neighborhood of the boundary of the polyhedral set.

It is obviously desirable to generalize this cutting construction to non-Abelian (compact) groups, and a number of approaches have appeared in the literature, though so far with fewer applications (see though \([MW12]\) for a recent use). Notice that, given a Hamiltonian \( K \)-orbifold, one can always apply an Abelian cut with respect to the action of the maximal torus \( T_K \), but the resulting cut space will in general only have an action by \( T_K \), no longer by \( K \). A first construction of a non-Abelian cut was given by Woodward in \([Woo96]\), and further detailed by Meinrenken \([Mei98]\). This construction gives, for a Hamiltonian action of a compact group \( K \) on a symplectic orbifold \( M \) and a polyhedral set \( P \) in the positive Weyl chamber of \( K \) that satisfies some conditions a new space, \( M_P \), whose Kirwan polytope is the intersection of \( P \) and the Kirwan polytope of \( M \).

Woodward’s construction is surgical in nature, in the style of (2): compose the moment map \( \mu_K \) with the quotient from \( \mathfrak{t}^* \) to the positive Weyl chamber \( \mathfrak{t}^*_+ \), take the pre-image of \( P \) under this map, and again collapse certain circle actions on the pre-images of the facets (i.e. locally apply an abelian symplectic cut with respect to these circle actions). Unlike the Abelian case, these circle actions do not extend to global actions on \( M \), essentially because the map to \( \mathfrak{t}^*_+ \) is not smooth everywhere. Intuitively, this explains why cutting in the non-Abelian case is a more subtle notion than in the case of torus actions. For instance, in contrast to the Abelian case, non-Abelian cutting need not result in a Kähler structure on \( M_P \) if \( M \) was Kähler. Indeed, in \([Woo98]\) Woodward considers a co-adjoint orbit of \( U(3) \) (which is of course Kähler), applies a non-Abelian symplectic cut with respect to the action of \( U(2) \subset U(3) \), and shows, using earlier work of Tolman \([Tol98]\), that the resulting cut space does not posses any compatible Kähler structure.
Besides the construction of [Woo96, Mei98] two other definitions labeled symplectic cutting for non-Abelian group actions have appeared in the literature, one given by Paradan in [Par09] (for general compact $K$) and one by Weitsman [Wei01] (for $K = U(n)$, also discussed by Dancer and Swan in [DS10]). These authors used their constructions in the context of geometric quantization of non-compact Hamiltonian $K$-spaces with proper moment maps. In both cases the cut spaces were defined as symplectic reductions by $K$ of $M \hat{\times} A$, where $A$ is a symplectic (in fact Kähler, even complex algebraic) space equipped with Hamiltonian left and right actions of $K$. In the construction of Paradan $A$ is a projective smooth (toroidal) compactification of $K_{\mathbb{C}}$, in the construction of Weitsman $A = M_{n \times n}(\mathbb{C})$. Since symplectic reduction preserves Kähler structures, these symplectic cuts always result in Kähler spaces if $M$ is Kähler. A priori it is unclear how they are related to Woodward’s construction, in fact both Paradan and Weitsman state their constructions are different.

It is the aim of this note to show that in good cases a global quotient counterpart, in the style of (1), to the construction of Woodward does exist. Like in the Abelian case this allows for the cut to be understood in Kähler geometry and even in algebro-geometric terms if $M$ is Kähler or an algebraic variety to begin with. As a consequence it follows that the construction of Paradan is a special case of the construction of Woodward.

In order to do this we proceed in two steps: the first involves the notion of a universal cut, given as the symplectic cut of the group $K$ acting on its own cotangent bundle $T^*K$. We show that for a sufficiently general $P$ the cut space $M_P$ can be obtained as the symplectic reduction of the Cartesian product of $M$ with this universal cut $(T^*K)_P$:

$$M_P \cong \left( M \times (T^*K)_P \right) \bigg/ K.$$  

(3)

This is highly reminiscent of the symplectic implosion construction of Guillemin, Jeffrey and Sjamaar [GJS02], for which the action of the compact group on its own cotangent bundle also provided a universal implosion.

After establishing this we can now focus our attention solely on discussing $(T^*K)_P$, which will take up the bulk of the paper. At this point, we restrict ourselves even further to cuts where the polyhedral set is given by the intersection of a Weyl-invariant polyhedral set in $t^*$ with $t^*_+$ (with some mild extra conditions, an example is given in Figure 1). Though restrictive this is still sufficient to obtain compact $M_P$ if the original moment map was proper. In these cases we then establish a global construction for the universal cut, as a symplectic reduction or GIT quotient of a certain affine variety. This construction appeared recently in other work of the authors, [MT11], were $(T^*K)_P$, which in algebraic geometry is a compactification of
was shown to be a moduli spaces of $K_C$-bundles on chains of projective lines.

\[ A \mapsto \sqrt{-\det \left( A^*A - \frac{1}{2} \text{Tr}(A^*A)I_{2\times 2} \right)}, \]

The main technical tool that allows us to do this is the remarkable Vinberg monoid, introduced in [Vin95b]. One can interpret this monoid as the total space of a particular $K_C \times K_C$-equivariant degeneration of $K_C$, in such a way that the degenerate fibers now do posses the extra needed symmetry. The simplest non-trivial example of this is $K_C = SL(2, \mathbb{C})$. The function to the positive Weyl chamber which one uses to apply a symplectic cut à la Woodward here is

The outline of the paper is as follows: in Section 2 we discuss some preliminaries and we describe the non-Abelian cut construction as given in [Woo96, Mei98]. To set the tone for the rest of the paper we also recall the Delzant construction of toric orbifolds and show that it can be interpreted as an (Abelian) symplectic cut of the cotangent bundle of the compact torus in the vein described above; this reinterpretation even extends its use. In Section 3.1 we then restrict to cutting with respect to a universal polyhedral set, and show (3). In 3.2 we further restrict to the case where the (outward) normal vectors to the faces of the polyhedral set are all in the positive Weyl...
ON NON-ABELIAN SYMPLECTIC CUTTING 5

chamber. We recall the Cox-Vinberg construction introduced by the authors in [MT11], and show that it corresponds in symplectic geometry to the cut of $T^*K$. This allows us to formulate in Corollary 3.5 the generalization of (1) to the non-Abelian case, as a torus-quotient of the total space of a degeneration of $M$ based on the Vinberg monoid. In [11] we mention how this recovers the cuts used by Paradan. We briefly discuss the cut of Weitsman in [12]. This construction, which applies to Hamiltonian $U(n)$-actions, is not a special case of Woodward’s definition, but it can be described through a local surgery method which we outline. Finally, in Appendices A and B we describe some of the symplectic geometry of complex reductive groups and spaces of matrices, necessary for the proof of Theorem 3.4.

Acknowledgements. The authors would like to thank Eugene Lerman, Reyer Sjamaar, Chris Woodward, Andrew Swann, Hans-Christian Herbig, Brendan McLellan, Lisa Jeffrey and, via MathOverflow, Reimundo Heluani and Peter Kronheimer for useful conversations.

2. Preliminaries

2.1. Notation & basic conventions. Let $K$ be a compact (connected) Lie group with Lie algebra $\frak{t}$, and $G = K_{\mathbb{C}}$ its complexification, a complex reductive group. We fix a maximal torus $T \subset K$ with Lie algebra $\frak{t}$, giving $T_{\mathbb{C}} \subset G$, and we denote the Weyl group by $W$. We choose (closed) positive Weyl chambers, denoted by $t_+$ and $t_+^*$. We use $\langle \ldots \rangle$ for the pairing between $\frak{t}$ and $\frak{t}^*$, and we shall denote by $\tau$ the involution given by $\tau(x) = -w(x)$, where $w$ is the longest element of $W$.

We say that a variety $M$ is semiprojective if it is projective over an affine. We shall use symplectic reduction, Kähler quotients and geometric invariant theory (GIT) quotients, and shall denote them all by

$$M/\xi K \quad \text{or} \quad M/\xi G,$$

where $\xi$ either indicates the central value in $\frak{t}^*$ at which the symplectic reduction is taken, or the linearization used for the GIT-quotient.

All the GIT-quotients we encounter will have no properly semistable points. Moreover we shall always consider the orbifold (smooth Deligne-Mumford stack with trivial generic stabilizer) $[M^*/G]$, and we shall abuse notation by still referring to this stack-theoretic quotient as the GIT-quotient rather than to its coarse moduli space (which is what is normally understood as the GIT-quotient). Likewise we shall be somewhat cavalier in the symplectic category when talking about orbifolds and Hamiltonian group actions on them, we refer to [LM12] for all background.

We have actions of $K$ on itself and on $G$, which we shall denote uniformly by $L_k(g) = kg$ and $R_k(g) = gk^{-1}$. We shall identify elements in $\frak{t}$ with left
invariant vector fields and as such obtain identifications

\[ TK \cong K \times \mathfrak{t} \quad \text{and} \quad T^*K \cong K \times \mathfrak{t}^*. \]

The actions \( \mathcal{L} \) and \( \mathcal{R} \) of \( K \) on \( K \) lift to \( T^*K \), and in the above trivialization they are given by

\[ \mathcal{L}_k(k, \lambda) = (\kappa k, \lambda) \quad \text{and} \quad \mathcal{R}_k(k, \lambda) = (\kappa k^{-1}, \operatorname{Ad}_k^\ast \lambda). \]

Both are Hamiltonian with respect to the canonical symplectic form, with moment maps respectively given by

\[ \mu^\mathcal{L}(k, \lambda) = -\operatorname{Ad}_k^\ast(\lambda) \quad \text{and} \quad \mu^\mathcal{R}(k, \lambda) = \lambda. \]

Given a matrix \( A \in M_{N \times N}(\mathbb{C}) \), we shall denote its Hermitian conjugate (i.e. conjugate transposed) by \( A^* = \overline{A} \).

2.2. Labeled polytopes and stacky fans. As mentioned before, when making a symplectic cut, Abelian or non-Abelian, we will need to specify a rational polyhedral set \( P \), i.e. a set cut out by a finite number of half spaces determined by

\[ \langle \beta_i, x \rangle \leq \xi_i, \]

where the variable \( x \) ranges over \( \mathfrak{t}^* \), the \( \xi_i \) are real numbers, and the outward normal vectors \( \beta_i \) are integral vectors in \( \mathfrak{t}_\mathbb{Z} \). Often one takes the \( \beta_i \) to be minimally such, but when working in an orbifold setting it is useful to relax this condition, and to allow the \( \beta_i \) to be positive integer multiples of the minimal integral outward normal vectors to the facets of \( P \). One can indicate this by labeling the facets of \( P \) with positive integers, as done in [LT97]. This extra data makes the fan determined by \( P \) into a stacky fan as in [BCS05, FMN10], see Figure 2 for an illustration. As this creates no further complications otherwise, we shall throughout tacitly assume that such a choice of labeling or stacky fan has been made, which we shall indicate in the pictures by drawing the \( \beta_i \) as normal vectors to the facets of \( P \). In the non-Abelian situation we will restrict the \( P \) determined by the (5) to \( \mathfrak{t}_+^* \), we shall always assume that each half-space has a non-empty intersection with \( \mathfrak{t}_+^* \).

Moreover, whenever we want to interpret the cut in algebraic geometry we shall assume that also the \( \xi_i \) are rational, so that we can use the \( n \)-tuple \( \xi = (\xi_1, \ldots, \xi_n) \) to construct a fractional linearization (see e.g. [Tha96]) with respect to which we can take a GIT-quotient.

Because we stick to an orbifold context, the \( P \) will always be simple (but not necessarily Delzant). Most of what follows can however be generalized to stratified symplectic spaces, where the simple condition is no longer necessary.
2.3. The Delzant construction as a symplectic cut of $T^*T$. The celebrated construction by Delzant [Del88] realizes every (compact) toric manifold $M$ as a symplectic reduction of a complex vector space $\mathbb{C}^n$ (where $n$ is the number of facets of the moment polytope of $M$) by a subgroup of $U(1)^n$. In particular, if the polytope $P$ is described by the inequalities (5), the $\beta_i$ determine a short exact sequence

$$1 \to L \to U(1)^n \to T \to 1,$$

and Delzant shows that

$$M \cong \mathbb{C}^n / L.$$

The algebraic geometric equivalent of the Delzant construction is known as the Cox construction [Cox95], which realizes toric varieties as categorical quotients of an open subset of $\mathbb{C}^n$ by the complexification of $(U(1))^n$, and which is a GIT-quotient if the toric variety is (semi)projective.

For the Delzant construction in this form to work it is crucial that the sequence (6) is exact on the right (which is equivalent to saying that the $\beta_i$ generate $t$). This is always the case for compact toric manifolds, but often fails for toric manifolds that are non-compact but still have a proper moment map. E.g. for any compact torus $T$ the cotangent bundle $T^*T$ is a toric manifold, but the (proper) moment map

$$\mu_T : T^*T \cong T \times t^* \to t^* : (t, h) \to h$$

is surjective, and hence there are no $\beta_i$ at all. One can however formulate a slight variation on the Delzant construction, which is equivalent to the Delzant construction when the sequence (6) is exact on the right but also works for non-compact toric manifolds whose moment maps are proper onto a polyhedral set. Indeed, we always have that $U(1)^n$ acts on $\mathbb{C}^n \times T^*T$, in the usual way on the first factor and by the cotangent lift of the action.
\[ \beta : U(1)^n \subseteq T \] determined by the \( \beta_i \) on the second. Then one can simply use
\[ M \cong \left( \mathbb{C}^n \times T^*T \right) / U(1)^n = (T^*T)_\beta. \]

This variation has the additional feature that it manifestly realizes the toric manifold as an (Abelian) symplectic cut of \( T^*T \). Visually we can just interpret every factor of \( U^1 \) cutting down the surjective image of the moment map for the action of \( T \) on \( T^*T \) by the corresponding half-space, finally resulting in the desired polyhedral set \( P \).

2.4. Non-Abelian symplectic cutting. We shall briefly review the construction given in [Woo96, \S 8] and [Mei98, \S 6]. Strictly speaking Woodward introduced the cut with respect to a single hyperplane, the natural generalization to polyhedral sets was given by Meinrenken, whose exposition we shall summarize.

Let \( M \) be a Hamiltonian \( K \)-orbifold, with moment map \( \mu_K : M \rightarrow \mathfrak{k}^* \). We have \( \mathfrak{t}^*/W \cong \mathfrak{t}^*/K \), and we can identify \( \mathfrak{t}^*/W \) with \( \mathfrak{t}_+^*/q \), a fundamental domain for the \( W \)-action. As the invariant part under the coadjoint representation of \( T_K \) on \( \mathfrak{k}^* \) we have a canonical inclusion \( \mathfrak{t}_+^* \hookrightarrow \mathfrak{t}^* \), and in fact the triangle
\[
\begin{array}{ccc}
\mathfrak{t}^* & \longrightarrow & \mathfrak{t}^* \\
\searrow & & \searrow \\
\mathfrak{t}_+^* & \cong & \mathfrak{t}^*/W \cong \mathfrak{t}^*/K
\end{array}
\]
commutes. We denote by \( \Phi \) the composition
\[ \Phi : M \xrightarrow{\mu_K} \mathfrak{t}^* \xrightarrow{q} \mathfrak{t}_+^*. \]

By a theorem of Kirwan [Kir84] \( \Phi(M) \) is a polytope if \( M \) is compact, often referred to as the Kirwan polytope. Let now a polyhedral set \( P \) be given in \( \mathfrak{t}_+^* \), determined by inequalities (5), that satisfies a few extra properties (see Definition 2.1 below). The basic idea is to cut with respect to the functions \( f_i = \langle \beta_i, \Phi(\cdot) \rangle \) – i.e. take the pre-image of \( P \) under \( \Phi \) and collapse by a circle action that has \( f_i \) as Hamiltonian on the \( i \)-th facet. The functions \( f_i \) are however not globally smooth (because \( q \) is not), and therefore cannot generate global \( U(1) \) actions. The approach of [Woo96] and [Mei98] is therefore to just work locally, and observe that this is sufficient.

\[ ^1\text{By using non-Abelian cutting this implies that if } M \text{ is not compact but has a proper moment map then } \Phi(M) \text{ is a locally polyhedral set – this was also proven (before the advent of symplectic cutting) in [HNP94]. We shall abuse terminology and still refer to } \Phi(M) \text{ as the Kirwan polytope.} \]
In what follows, when we refer to a ‘face of $P$', we just mean the intersection of $P$ with a finite number of hyperplanes $\langle \beta_i, x \rangle = \xi_i$, i.e. the walls of the Weyl chamber itself are not taken into account. Likewise the interior of $P$ is just given by

$$\text{int}(P) = t_+^* \cap \left\{ \langle \beta_i, x \rangle < \xi_i \right\},$$

in particular this can contain elements on walls of the Weyl chamber. We shall denote faces of $P$ by $P_I$, where $I \subset \{1, \ldots, n\}$ indicates which inequalities to set to equalities. For each such $P_I$, we shall denote by $T_I$ the group $\prod_{i \in I} U(1))$, which comes with a morphism $\phi_I$ to $T$ by the $(\beta_i)_{i \in I}$.

**Definition 2.1.** Given $M$ as above, we say $P$ is admissible with respect to $M$ if the following three conditions are satisfied:

1. The affine hyperplanes $\langle \beta_i, x \rangle = \xi_i$ are all transversal (i.e. $P$ is simple in $\mathfrak{u}$).
2. For all faces $P_I$ of $P$, and all $x \in \mu^{-1}_K(P_I \cap t_+^*)$, $t_x \cap t_I = \{0\}$, where $t_x$ is the Lie algebra of the stabilizer of $x$ in $K$.
3. For all faces $P_I$ of $P$ meeting a face $\sigma$ of $t_+^*$ in $\Phi(M)$, the tangent space to $P_I$ contains the affine subspace perpendicular to $\sigma$.

Given a face $\sigma$ of $t_+^*$, we denote by $K_\sigma$ the stabilizer group for the coadjoint action, and $A_\sigma$ its connected center. Since $T \subset K_\sigma$, we always have $A_\sigma \subset T$. For any such $\sigma$, write

$$U_\sigma = \bigcup_{\sigma \in \tilde{\sigma}} \text{int}(\tilde{\sigma}), \quad \text{and} \quad Y_\sigma = \mu^{-1}(\text{Ad}^*(K_\sigma)(U_\sigma)).$$

By the symplectic cross section theorem ([Mei98, Theorem 6.1], [GS90, §26]), we have that $Y_\sigma$ is a Hamiltonian $K_\sigma$-space, and the action of $A_\sigma$ on $Y_\sigma$ extends uniquely to an action on $M_\sigma = \Phi^{-1}(U_\sigma)$ that commutes with the action of $K$. The moment map for this $A_\sigma$ action is given by

$$\mu_{A_\sigma} = \pi_\sigma \circ \Phi,$$

where $\pi_\sigma$ is the natural morphism $t^* \rightarrow a_\sigma^*$. Notice that this action of $A_\sigma$ is in general not given as the induced action of a subgroup of $K$.

Now suppose we have a $P$ admissible with respect to $M$. By condition (3) of Definition 2.1 we have that $\phi_I(T_I)$ is a subgroup of $A_\sigma$ for all $\sigma$ with $P_I \cap \sigma \neq \emptyset$. One can choose a neighborhood $\sigma \subset V_\sigma \subset U_\sigma$ for any $\sigma$ such that

$$V_\sigma \cap P = V_\sigma \cap \pi_\sigma^{-1}(P \cap a_\sigma^*)$$

(observe that we have canonical inclusions $a_\sigma^* \subset t^*$). By using the $A_\sigma$-actions we can take the (Abelian) symplectic cuts $\Phi^{-1}(V_\sigma)_{P_\sigma}$, where $P_\sigma = P \cap a_\sigma^*$. Moreover, the $\Phi^{-1}(V_\sigma)$ cover $M$, and we can glue the local cuts $\Phi^{-1}(V_\sigma)_{P_\sigma}$
together to obtain a new Hamiltonian $K$-orbifold, which we refer to as the cut space $M_P$. We have
\[ \Phi(M_P) = \Phi(M) \cap P, \]
and there is a decomposition into symplectic suborbifolds
\[ M_P = \bigcup_{P_I \subset P} \Phi^{-1}\left(\text{int}(P_I)\right)/T_I. \]

**Definition 2.2.** We say $P$ is universal if $P$ is admissible with respect to $T^*K$, equipped with the $K$-action $\mathcal{R}$.

This just means that $P$ is simple and that if a face of $P$ intersects a wall of the Weyl chamber $t^*_+$, it does so perpendicularly, as illustrated in Figure 3.

![Figure 3. Examples of universal polyhedral sets $P$ for $K = SU(3)$.](image1)

**Remark 1.** Given $M$, not all admissible polyhedral sets need to be universal. The cut employed by Woodward in [Woo98] on a coadjoint $U(3)$-orbit (see Figure 4) cannot be made with respect to a universal polyhedral set.

![Figure 4. The cut employed in [Woo98].](image2)

3. **A global quotient construction for cuts**

3.1. **The universal cut.** We begin by introducing the notion of a universal cut, i.e. a cut of $T^*K$, as a tool for studying cuts for arbitrary orbifolds.
This idea is essentially applicable to any universal procedure one can apply to a Hamiltonian $K$-orbifold, and was used in \cite{GJS02} for symplectic implosions.

**Proposition 3.1.** Let $M$ be a Hamiltonian $K$-orbifold, and let $P$ be a universal polyhedral set in $t^*_+$, admissible with respect to $M$. Then

$$M_P \cong \left( M \times (T^*K)_P \right)_{/0} K,$$

where we cut $T^*K$ with respect to the action $R$, and the diagonal action of $K$ on $M \times (T^*K)_P$ uses the $L$-action on the second factor.

The above choices of actions are just made for convenience. Notice that cutting $T^*K$ using a polyhedral set $P$ and the action $R$ is the same as cutting it with respect to $\tau(P)$ and the action $L$.

**Proof.** First recall (see e.g. \cite[Lemma 4.8]{GJS02}) that given any $M$ as above, we have that, as Hamiltonian $K$-orbifolds,

$$M \cong (M \times T^*K)_{/0} K.$$

To finalize the proof it just suffices to observe that, given two commuting Hamiltonian actions, symplectic cutting for one (with respect to a universal and admissible polyhedral set) and symplectic reduction for the other commute.

In the Abelian case $K = T$ Proposition \ref{prop:abelian_symplectic_cut} together with (7), just states the well-known fact that the Abelian symplectic cut can be realized as the reduction by $T$ of the product of $M$ and the toric orbifold determined by $P$.

### 3.2. Universal cuts and toroidal $G$-embeddings.

#### 3.2.1. Outward-positive polyhedral sets.

Because of Proposition \ref{prop:universal_symplectic_cut}, we can restrict ourselves to studying $(T^*K)_P$ when cutting with respect to a universal $P$. For the rest of the paper, we shall make a further restriction on the $P$ that we use:

**Definition 3.2.** A polyhedral set $P$ in $t^*_+$ determined by a finite number of inequalities of the form (6) is said to be outward-positive if all the $\beta_i$ are contained in the positive Weyl chamber $t_+$.

See Figure 5 for some examples of outward-positive polyhedral sets (note that none of the universal polyhedral sets of Figure 3 are outward-positive).
Remark 2. When cutting with an outward-positive polyhedral set $P$, there is little loss of generality in assuming that $P$ is also universal. Indeed, suppose the moment map for $M$ is proper and $P$ is admissible with respect to $M$ and outward-positive, but not necessarily universal. Then one can always impose some extra inequalities to obtain a new outward-positive polyhedral set $\tilde{P} \subset P$ such that $\tilde{P}$ is universal and $M_P \cong M_{\tilde{P}}$, see Figure 6 for an example. This is not true if $P$ is not outward-positive.

An outward-positive polyhedral set $P$ can always be written as the intersection of $t_+^*$ with a $W$-invariant polyhedral set $WP$ in $t^*$, if $P$ is moreover also universal this $WP$ will have all of its vertices in the interior of Weyl chambers. Given such a $P$ we shall denote its (stacky) fan of normal vectors by $\Sigma$, the support of $\Sigma$ is entirely contained in $t_+$.

Our aim is now to show that if the polyhedral set is outward-positive then $(T^*K)_P$ can be understood in algebro-geometric terms as a (polarized) toroidal spherical embedding of $G$.

These embeddings where studied in [MT11], where it was shown they can be interpreted as moduli spaces of framed $G$-bundles on chains of projective lines. In [MT11] they were denoted by $\mathcal{M}_G(\Sigma)$, but since we shall always consider them here with a choice of a (rational) polarization we shall refer to them as $\mathcal{M}_G(P)$. These are smooth Deligne-Mumford stacks, with trivial generic stabilizer and a $G \times G$-action on them. Their coarse moduli spaces
are semiprojective toroidal spherical $G \times G$-varieties. If $P$ is compact the $\mathcal{M}_G(P)$ are compactifications of $G$; $P$ can then also be described as the intersection of $\mathfrak{t}_G^*$ with the convex hull of the Weyl orbit of a finite number of points in the interior of $\mathfrak{t}_G^*$.

Of particular relevance here is that in [MT11] a construction was given, dubbed the Cox-Vinberg quotient, that realizes $\mathcal{M}_G(\Sigma)$ as a torus quotient of an open subvariety of a certain affine variety. If $\mathcal{M}_G(\Sigma)$ is semiprojective, which is always the case in our current context, the Cox-Vinberg quotient can be understood as a GIT-quotient. We shall here consider it as a symplectic reduction, in which sense it generalizes the variant on the Delzant construction outlined in Section 2.3.

Notice that, if $(T^*K)_P$ is a compact manifold, the Delzant conjecture, now proven in [Kno11] and [Los09], shows that $(T^*K)_P$ is determined up to equivariant symplectomorphism by its Kirwan polytope, since it is multiplicity-free. This could be used to show the symplectomorphism we want to establish. Our strategy for the proof is entirely different however, as we aim to clarify the relationship between the construction of $(T^*K)_P$ as a symplectic cut and the Cox-Vinberg quotient. This has as an added advantage that it also works if $(T^*K)_P$ is not compact or if it is an orbifold (or possibly even if it is singular and interpreted as a stratified symplectic space). It seems very plausible that a generalization of the Delzant conjecture holds true for Hamiltonian $K$-orbifolds with proper moment maps; it is well-known however that, unlike in the Abelian case, the Delzant conjecture is false when one allows singular spaces.

3.2.2. The Cox-Vinberg construction. At the basis of this Cox-Vinberg quotient construction lies the Vinberg monoid $S_G$ of a (complex) reductive group $G$. This is a reductive affine monoid, with group of units

$$\tilde{G} = (G \times Z)/ZG,$$

here $Z$ is a torus with a given isomorphism to the maximal torus $T_G$, and $ZG$ is the antidiagonal embedding of the center of $G$. For $G$ semisimple $S_G$ was introduced by Vinberg in [Vin95b], where it was called the enveloping semigroup of $G$. For arbitrary reductive $G$ the definition was extended by Alexeev and Brion in [AB04] (this generalization shares most of the properties $S_G$ has if $G$ is semisimple, with the possible exception of the universal property exhibited by Vinberg). It can be described as follows: by the algebraic Peter-Weyl theorem, the ring of regular functions of any complex reductive group $G$ decomposes as a $G \times G$-representation as

$$k[G] = \bigoplus \lambda k[G]_\lambda,$$

Indeed, this strategy was used by Manolescu and Woodward for the wonderful compactification of an adjoint group in the unpublished [MW08]. We are grateful to the authors for sharing this manuscript with us.
where \( k[G]_\lambda \) are the matrix-coefficients of the irreducible representation with highest weight \( \lambda \) as functions on \( G \). The Vinberg monoid is defined by taking a subring of \( k[\hat{G}] \). Let \( \mathfrak{X}_G \) be the character lattice for \( T_G \). The character lattice of \( T_G \) is then given by

\[
\mathfrak{X}_G = \left\{ (x, y) \in \mathfrak{X}_G^2 \mid x - y = \sum n_i \alpha_i, \ n_i \in \mathbb{Z} \right\},
\]

where the \( \alpha_i \) are the positive simple roots of \( G \) (or \( K \)).

The Vinberg monoid is now defined (as a variety) by

\[
S_G := \text{Spec} \left( \bigoplus_{\lambda \in \mathfrak{X}_G \cap Q_G} k[\hat{G}]_\lambda \right),
\]

where \( Q_G \) is the cone

\[
Q_G := \left\{ (x, x + \sum m_i \alpha_i) \mid x \in \mathfrak{t}^*_+ \right\}.
\]

Vinberg shows \( S_G \) is a monoid, moreover the affine GIT-quotient

\[
\mathbb{A} := S_G \left/ (G \times G) \right.
\]

is the smooth affine toric variety for the torus \( Z/ZG \) determined by the cone spanned by the \( \alpha_i \). The fibers of \( \pi_G : S_G \rightarrow \mathbb{A} \) over the open orbit of \( \mathbb{A} \) are all isomorphic to \( G \) as \( G \times G \)-varieties, the fiber over the \( Z/ZG \)-fixed point of \( \mathbb{A} \) is referred to as the asymptotic semigroup of \( G \) by Vinberg [Vin95a].

Suppose now that a polyhedral set as above is given, with (outward) normal vectors \( \beta_i \). These \( \beta_i \) determine morphisms \( \phi_{\beta_i} \) from \( \mathbb{G}_m = \mathbb{C}^* \) into \( Z \) and hence also into \( Z/ZG \). Since moreover all the \( \beta_i \) are contained in the positive Weyl chamber \( \mathfrak{t}_+ \) the collectively morphism \( \phi_\beta \) from \( \mathbb{G}_\beta := \mathbb{G}_m^n \) to \( Z/ZG \) extends to a morphism of monoids \( \overline{\phi}_\beta \) from \( \mathbb{A}_\beta := \mathbb{C}^n \) to \( \mathbb{A} \). We can now take the fibered product

\[
\begin{array}{ccc}
S_{G,\beta} & \longrightarrow & S_G \\
\downarrow \quad \overline{\phi}_\beta & & \downarrow \pi_G \\
\mathbb{A}_\beta & \longrightarrow & \mathbb{A},
\end{array}
\]

This is a monoid with group of units \( G \times \mathbb{G}_\beta \), flat over \( \mathbb{A}_\beta \), with generic fibers isomorphic to \( G \). Note that \( \overline{\phi}_\beta \) can only be the identity if \( K \) is adjoint and the \( \beta_i \) are the fundamental coweights \( \varpi_i^* \). This is also the reason behind the extra factor occurring in the \( SL(2, \mathbb{C}) \) example given in the introduction: the \( S_{SL(2, \mathbb{C}),\beta} \) one wants to consider to cut \( SL(2, \mathbb{C}) \) is not just \( M_{2 \times 2}(\mathbb{C}) \) (which is \( S_{SL(2, \mathbb{C})} \)), but rather matrices in \( M_{2 \times 2}(\mathbb{C}) \) together with a choice of a square root of their determinant.
It is straightforward to check that we can describe $S_{G,\beta}$ directly as follows:

**Lemma 3.3.** If we define the cone

$$Q_{G,\beta} := \left\{ (x, \langle \beta, x \rangle + m_i) \mid x \in \mathfrak{t}_+^* \right\} \subseteq \mathfrak{t}^* \oplus (u(1))^*$$

we have

$$S_{G,\beta} = \text{Spec} \left( \bigoplus_{\lambda \in \mathfrak{x}_{G \times \mathbb{C}G} \cap Q_{G,\beta}} k[G \times G_{\beta}]_\lambda \right).$$

Consider now the action of $G_{\beta}$ on $S_{G,\beta}$, given by the obvious action on $A_{\beta}$ and the action on $S_{G}$ induced through the morphism $G_{\beta} \to Z$. It is proven in [MT11] that we have

$$S_{G,\beta} / \xi \cong \mathcal{M}_G(P),$$

for our purposes we can take this as the definition of $\mathcal{M}_G(P)$.

### 3.2.3. Hamiltonian geometry of $S_{G,\beta}$

We want to show that, if we interpret this quotient in symplectic geometry, the result is symplectomorphic to the corresponding cut of $T^*K$. In order to do so we need to choose a symplectic structure on $S_{G,\beta}$; we shall choose one coming from an affine embedding by restricting the Euclidean metric on the ambient space.

In particular, we shall choose an embedding $\iota$ that realizes $S_{G,\beta}$ as a closed submonoid of some $M_{N \times N}(\mathbb{C})$. This is always possible, see [Vin95b, Remark on page 169]. In this way $S_{G,\beta}$ becomes Kähler\(^3\), and the GIT construction will lead to an variety that is semiprojective, which is again Kähler by combining the Fubini-Study metric with the Euclidean one. We shall use a maximal compact subgroup $K \times U(1)^n$ of $G \times G_{\beta}$ compatible with this Kähler structure.

Notice that our only ambition here is to relate a purely algebraic construction to a purely symplectic one, and we can therefore just choose a compatible Kähler structure to serve our purposes. The full problem of describing all of the admissible Kähler structures that can occur on this symplectic cut is more subtle and not addressed here.

It follows from [Sja98, Theorem 4.9] that the cone $Q_{G,\beta}$ given in (13) is the image under $\Phi_{K \times U(1)^n}$, i.e. the moment map $\mu_{K \times U(1)^n}$ for the $\mathcal{R}$-action of $K \times U(1)^n$ on $S_{G,\beta}$ composed with the projection on the positive Weyl chamber $\mathfrak{t}_+^* \oplus (u(1))^*$ (the map $\Phi_{K \times U(1)^n}$ for the $\mathcal{L}$-action is given by composing the one for the $\mathcal{R}$-action with $\tau$).

\(^3\text{Strictly speaking, since } S_{G,\beta} \text{ a priori might have singularities, it would have to be interpreted as a stratified symplectic space. We can ignore these issues however, since the GIT-stable subvariety of } S_{G,\beta} \text{ is smooth, by [MT11, Theorem 7.1] and [Vin95b, Theorem 8].} \)
Lemma B.3 gives us moreover a section of the moment map $\mu_{K \times U(1)^n}$, which we shall simply denote by $s$. In what follows we shall furthermore denote the moment map for the $U(1)^r$-action on $S_{G,\beta}$ by $\mu$.

### 3.2.4. Correspondence results

With all of this set up, we are ready for our main result:

**Theorem 3.4.** There is a $K \times K$-equivariant symplectomorphism of (real) orbifolds

$$ (T^*K)_P \cong \mathcal{M}_G(P). $$

**Proof.** We begin by establishing local (orbifold) diffeomorphisms. We shall follow here the notation used in Section 2.4. Recall that the local descriptions of the non-abelian cut were given as abelian symplectic cuts $\Phi^{-1}(V_\sigma)_{P_\sigma}$ using the local action of $A_\sigma$ that commuted with the action of $K$. In turn these abelian symplectic cuts are defined as

$$ \Phi^{-1}(V_\sigma)_{P_\sigma} = \left(\Phi^{-1}(V_\sigma) \times \mathbb{C}^r\right)_j U(1)^r, $$

where $J$ denotes the equations among all inequalities (5) needed to describe $P_\sigma$ — for convenience we shall assume that $J = \{1, \ldots, r\}$. In what follows we shall need to make one small modification to this description: rather then using $V_\sigma$ that are neighborhoods of all of $\sigma$ in $U_\sigma$ satisfying (11), we shall just use neighborhoods $\tilde{V}_\sigma$ of $\sigma \cap P$ in $U_\sigma$ that satisfy (11) and moreover have the property that the inequalities (5) are strict for all $j \not\in J$, as illustrated in Figure 7. One easily sees that $\Phi^{-1}(V_\sigma)_{P_\sigma} = \Phi^{-1}(\tilde{V}_\sigma)_{P_\sigma}$ if $V_\sigma \cap P = \tilde{V}_\sigma \cap P$.

![Figure 7. Example of $\tilde{V}_\sigma$.](image)

We shall now write down a morphism $T_\sigma$ from $\Phi^{-1}(\tilde{V}_\sigma) \times \mathbb{C}^r$ to $S_{G,\beta}$, for which we describe elements in $\mathbb{C}^r$ in polar coordinates as $(e^{i\theta_j}r_j)_{j \in J}$ — we normalize the moment map of $U(1)^r$ on $\mathbb{C}^r$ to be $(r_j^2)_{j \in J}$. We define

$$ T_\sigma : (k, (e^{i\theta_j}r_j)_{j \in J}) \mapsto (k, (e^{i\theta_j})_{j \not\in J}, (1, \ldots, 1)) \cdot s\left(\gamma, (r_j^2 + \langle \beta_j, q(\gamma) \rangle)_{j \in J} \right), $$
where ‘.’ denotes the $L$-action. This is well-defined: because of the restrictions to $\tilde{V}_\sigma$ the argument of $s$ indeed lies in its domain, i.e. $Ad^K(K \times U(1)^n)(Q_{G,\beta})$, and secondly, there is an ambiguity in the $e^{i\theta_j}$ whenever $r_j = 0$, but one checks that the action of $e^{i\theta_j}$ on both $\mathbb{A}_\beta$ and (using [Vin95b, Theorem 7]) on $S_G$, and hence on the image of $T_\sigma$, is trivial whenever $r_j = 0$.

We leave it as an exercise to the reader to show that $T_\sigma$ is an embedding and equivariant for the action of $K \times K$ and $U(1)^r$, where $K \times K$ acts in the obvious way on $\Phi^{-1}(\tilde{V}_\sigma)$ and $U(1)^r$ acts diagonally on the product, on $\Phi^{-1}(\tilde{V}_\sigma)$ through $A_\sigma$ and on $\mathbb{C}^r$ in the obvious way. Using (10) one sees that the moment map for this $U(1)^r$-action on $\Phi^{-1}(\tilde{V}_\sigma) \times \mathbb{C}^r$ is given by

$$( (k, \gamma), (e^{i\theta_j}r_j)_j ) \mapsto (r_j^2 + \langle \beta_j, q(\gamma) \rangle)_j,$$

from which it follows that the $(\xi_1, \ldots, \xi_r)$-level set of this moment map gets send by $T_\sigma$ to $\mu^{-1}(\xi) \subset S_{G,\beta}$.

One can now think of the symplectic reduction $S_{G,\beta}/K U(1)^n$ as happening in two stages: first take the reduction by the first $r$ factors of $U(1)^n$, and then by the remaining $n-r$ ones. If the image of $T_\sigma$ intersects an orbit for the last $n-r U(1)$-factors it does so transversely and in a single point (the latter follows by using Lemma [B.1] and [Vin95b, Theorem 7]); as a result $T_\sigma(\Phi^{-1}(\tilde{V}_\sigma) \times \mathbb{C}^r)_{\ell \in \mathbb{Z}} U(1)^r$ provides an orbifold slice for the level set of the moment map for the last $n-r U(1)$-factors acting on $S_{G,\beta}^{\mathbb{Z}}_{\ell \in \mathbb{Z}} U(1)^r$. This establishes the local diffeomorphism.

The $\Phi^{-1}(\tilde{V}_\sigma)_P$ cover $(T^*K)_P$ and every $U(1)^n$ orbit in $\mu^{-1}(\xi)$ meets some $T_\sigma(\Phi^{-1}(\tilde{V}_\sigma))$, essentially since it follows from (13) that

$$\Phi_K(\mu^{-1}(\xi)) = P,$$

where $\Phi_K = q \circ \mu_K : S_{G,\beta} \to t^*_+$. Therefore we have a global diffeomorphism between the orbifolds.

To show that this is a symplectomorphism, it suffices to show it for a dense open subset. Let $\sigma^0$ be the minimal face of $t^*_+$ (containing the origin). We can take as $\tilde{V}_{\sigma^0}$ the whole of int($P$). We have that $T_{\sigma^0}(\Phi^{-1}(\text{int}(P))) \times U(1)^n = \mu^{-1}(\xi) \cap G \times G_{\beta} \subset S_{G,\beta}$. Since the symplectic form on $S_{G,\beta}$ is obtained from $\iota$, Lemma [A.2] ensures that we can use Lemma [A.1] from which it follows that in the diagram

$$\begin{array}{ccc}
T_{\sigma^0}(\Phi^{-1}(\text{int}(P))) \times U(1)^n & \longrightarrow & \mu^{-1}(\xi) \subset S_{G,\beta} \\
\downarrow & & \\
\Phi^{-1}(\text{int}(P)) & \\
\end{array}$$

the pull-backs of the symplectic forms on $\Phi^{-1}(\text{int}(P))$ and $S_{G,\beta}$ coincide. $\square$
Finally from this we can conclude a non-Abelian version of (1):

**Corollary 3.5.** There is a natural symplectomorphism

\[(15)\quad M_P \cong \left(\frac{(M \times S_G)}{\mathbb{A}}\right) \times_{\mathbb{A}^\beta} \mathbb{A}^{\xi} U(1)^n.\]

**Proof.** It suffices to combine Theorem 3.4 with Proposition 3.1 and (14), and notice that since all group actions involved commute we can switch the order of the quotients. □

**Remark 3.** If \(K = T\) is a torus, \(S_G\) is just \(G = T_C\) and \(K\) is a point; (15) then just reduces to (7). If \(M\) is a semiprojective algebraic variety, we can think of \((M \times S_G)/K, 0\) as the total space of a flat degeneration of \(M\) over \(\mathbb{A}\); this family also appeared in [AB04, §7].

4. Comparison with constructions of Paradan and Weitsman

4.1. **Paradan.** As stated in the introduction, Paradan [Par09] defines non-Abelian symplectic cutting of \(M\) as the reduction

\[M_{\text{cut}} = (M \times A)/K,\]

where \(A\) is a smooth projective variety, which \(G \times G\)-equivariantly compactifies \(G\). Paradan constructs this by taking a finite collection of irreducible representations \(V_{\lambda_i}\) of \(G\), where all the highest weights \(\lambda_i\) are regular dominant weights, i.e. contained in the interior of \(t^*_+\). He shows that if the convex hull of the \(W\)-orbits of the \(\lambda_i\) is a Delzant polytope then one has an embedding

\[G \hookrightarrow \mathbb{P} \left( \bigoplus_i \text{End}(V_{\lambda_i}) \right),\]

and \(A\), the closure of \(G\) in this projective space, is a non-singular variety.

It follows from the theory of spherical embeddings (see e.g. [Pez10]) that all such \(A\) are toroidal spherical \(G \times G\)-varieties. If \(K\) is adjoint or \(Sp(n)\) (or a product of these), it even suffices to take a single regular \(\lambda_i\). In this case \(A\) will have a unique closed \(G \times G\) orbit, i.e. it will be a wonderful compactification of \(G\).

Any toroidal embedding of \(G\), in particular the non-singular ones used by Paradan, can be obtained from the Cox-Vinberg construction given in Section 3.2.2. It suffices to use as \(P\) the intersection of the convex hull of the \(W\)-orbits of the \(\lambda_i\) with \(t^*_+\) – it is easy to see this is a universal polytope. As a result the cut construction of Paradan can be seen as a special case of the cut of Woodward.
4.2. **Weitsman.** In [Wei01] Weitsman defines a symplectic cut for Hamiltonian $U(n)$-manifolds by

$$M_{\epsilon} = \left( M \times M_{n \times n}(\mathbb{C}) \right) \bigg/ \epsilon U(n),$$

where $\epsilon$ is a central value in $u(n)^*$. A surgery-type description for this construction was also given in [DS10, §3], we rephrase it here in the language we have used for the Woodward construction. We shall use as $T$ diagonal matrices in $U(n)$, as before we identify $u(n)$ with $u(n)^*$ by means of an invariant metric, and we use as positive Weyl chamber $t^n_+$. Define the subsets of $t^n_+$

$$P_{\epsilon, k} := \{ \lambda_1 \geq \cdots \geq \lambda_{n-k} > \lambda_{n-k+1} = \cdots = \lambda_n = \epsilon \},$$

Weitsman calls $M$ cuttable at $\epsilon$ if $\epsilon$ is a regular value of the moment map on $M \times M_{n \times n}(\mathbb{C})$, one then has (cfr. [Wei01, Remark 2.9]):

$$M_{\epsilon} = \bigcup_{k \in \{0, \ldots, n\}} \Phi^{-1}(P_{\epsilon, k}) \bigg/ \sim_k,$$

where $\sim_k$ is determined by dividing out by the $R$-stabilizer of $\sqrt{\frac{i}{h}}\mu_K(\cdot) \in M_{n \times n}(\mathbb{C})$ – all of these are isomorphic to $U(k)$. A major difference with the Woodward construction is that the groups one quotients out by on the boundary of the polytope $P_{\epsilon, 0}$ are non-Abelian. In particular, $M_{\epsilon} / U(n)$ itself is a subspace of $M_{\epsilon}$. It is also harder to see if $M$ is cuttable, compared to the conditions of Definition (2.1) for the Woodward construction.

The main aim of the cut in [Wei01] is to produce compact spaces out of non-compact $U(n)$-spaces with proper moment maps. For this purpose a single cut will in general not suffice, rather Weitsman takes a cut, reverses the symplectic structure, takes another cut, and reverses the symplectic structure again, to obtain $\overline{(M_{\epsilon})_\delta}$, which will always be compact.

**Appendix A. Symplectic structures on complex reductive groups**

As we want to compare a symplectic construction involving $T^*K$ with an algebraic construction involving $G$, we need a way to relate the two. This is provided by the following:

**Lemma A.1.** Let $G$ be a connected complex reductive group, the complexification of a compact Lie group $K$. Assume we have a symplectic structure $\omega_G$ on $G$, such that the two actions $L$ and $R$ of $K$ on $G$ are Hamiltonian
with moment maps $\tilde{\mu}^L$ and $\tilde{\mu}^R$. Assume further that we have a projection $\Pi: G \to K$ that is equivariant for $L$ and $R$, and whose fibers are Lagrangian for $\omega_G$. Then the morphism
$$\Psi: G \to K \times \tilde{\mu}^R(K) \subset T^*K: g \mapsto (\Pi(g), \tilde{\mu}^R(g))$$
is a $K \times K$-equivariant symplectomorphism onto an open submanifold of $T^*K$.

In particular if $\tilde{\mu}^R$ is surjective we have a symplectomorphism with all of $T^*K$. As $G/K$ is contractible this image always contracts onto $K$. Notice that the use of $\tilde{\mu}^R$ in the definition of $\Psi$ is a consequence of the choice we made to identify $T^*_K$ with $K \overset{\hat{\cdot}}{\to} k$ by means of left-invariant vector fields.

**Proof.** Observe first that since the two actions commute, $\tilde{\mu}^L$ is invariant for the $R$-action and vice versa. Since both actions are free and the orbits have half the dimension, we have that the differentials of $\tilde{\mu}^L$ and $\tilde{\mu}^R$ are surjective, from which one deduces that their images are open, and that the fibers of $\tilde{\mu}^R$ are the orbits of the $L$-action and vice versa. From this one checks straightforwardly that $\Psi$ is a $K \times K$-equivariant diffeomorphism which intertwines the moment maps.

To see that $\Psi$ is a symplectomorphism, observe that from the properties of $\Pi$ it follows at once that the fibers of $\Pi$ are transversal to the orbits (for both actions). At any point $g$ of $G$ we can therefore write any tangent vector $X$ as a sum of a ‘vertical’ part $X_v$, which is tangent to a fiber of $\Pi$, and a horizontal part $X_h$, tangent to the orbit of the $R$-action. Using the fact that the fibers of $\Pi$ are Lagrangian we have
$$\omega_G(X_h + X_v, Y_h + Y_v) = \omega_G(X_h, Y_h + Y_v) - \omega_G(Y_h, X_v),$$
and likewise for the pull-back of the symplectic form on $T^*K$. Since both $X_h$ and $Y_h$ are evaluations of vectorfields generated by $R$ at $g$, the contractions of the symplectic forms by them are determined by the moment maps $\tilde{\mu}^R$ and $\mu^R$. Since $\Psi$ intertwines these moment maps, evaluations of both forms are identical, and the result follows. \qed

The Cartan decomposition (see e.g. [Kna02, Theorem 6.31]) says that every element $g$ in $G$ can uniquely be written as $g = ke^{i\lambda}$, with $k \in K$ and $\lambda \in \mathfrak{f}$. As a consequence we obtain a canonical projection
$$\Pi_{cd}: G \to K: g \mapsto k$$
which is equivariant for $L$ and $R$. It turns out that if we equip $G$ with the Kähler form obtained from any faithful representation by restricting the Euclidean Kähler form on $GL(N, \mathbb{C}) \subset M_{N \times N}(\mathbb{C})$, we can use this $\Pi_{cd}$ to apply Lemma A.1. Indeed, we have
Lemma A.2. The fibers of $\Pi_{\text{cd}}$ are Lagrangian for the Kähler form on $G$ inherited from $M_{N \times N}(\mathbb{C})$.

Proof. This follows from a simple direct computation: the Kähler metric on $M_{N \times N}(\mathbb{C})$ can be written as

\[ g_E(A, B) = \text{Tr}(A B^*) \]

and hence the Kähler form can be written as

\[ \omega_E(A, B) = \Re(\text{Tr}(A (iB)^*)) = -\Im(\text{Tr}(A B^*)) . \]

Tangent vectors to a fiber of $\Pi_{\text{cd}}$ at a point $ke^{i\lambda}$ can be written as

\[ \frac{d}{dt} |_{t=0} ke^{i(\lambda+t\nu)} \]

with $\mu$ and $\nu$ elements of $u(N)$, i.e. anti-Hermitian matrices. We therefore need to evaluate

\[ \omega_E \left( \frac{d}{dt} |_{t=0} ke^{i(\lambda+t\nu)}, \frac{d}{ds} |_{s=0} ke^{i(\lambda+s\xi)} \right) = -\frac{\partial^2}{\partial t \partial s} |_{(0,0)} \Im(\text{Tr}(ke^{i(\lambda+t\nu)}(ke^{i(\lambda+s\xi)})^*)) \]

But for any anti-Hermitian $\alpha$ and $\beta$ one has that

\[ \text{Tr}(e^{i\alpha} e^{i\beta}) = \text{Tr}(e^{i\beta} e^{i\alpha}) = \text{Tr}(e^{i\alpha} e^{i\beta}) . \]

Hence any such $\text{Tr}(e^{i\alpha} e^{i\beta})$ is always real, and therefore (17) vanishes. □

Remark 4. There are at least two obvious ways one can equip $G$ with a Kähler structure: besides the one obtained from restricting the ambient Euclidean Kähler metric through an affine embedding (as we use in this paper), one can choose an invariant metric on $\mathfrak{k}$ and use this to identify $\mathfrak{k}$ and $\mathfrak{k}^*$. Using the Cartan decomposition this gives $K \times K$-equivariant diffeomorphisms

\[ G \cong K \times \mathfrak{k} \cong K \times \mathfrak{k}^* \cong T^* K. \]

The canonical symplectic structure on $T^* K$ and the complex structure on $G$ combine to a Kähler structure, which is discussed in [Hal97]. Both of these methods depend on a choice, but they are mutually exclusive.

Appendix B. Polar decomposition and moment maps

There is related area where we shall need the polar decomposition. Recall that any matrix $A$ in $M_{N \times N}(\mathbb{C})$ can be written as

\[ A = UP, \quad \text{with} \quad U \in U(N) \quad \text{and} \quad P = \sqrt{A^* A}. \]

In this decomposition $P$ is of course unique, but if $A$ is not invertible $U$ is not (for invertible complex matrices the Cartan decomposition and the polar decomposition coincide). Closely related to this is the fact that the
moment map for the $\mathcal{R}$-action of $U(N)$ on $M_{N \times N}(\mathbb{C})$ (equipped with the Euclidean Kähler metric) is given by

$$\mu^R(A) = iA^*A,$$

where we identify $u(N)$ with $u^*(N)$ by means of $\langle A, B \rangle = -\text{Tr}(AB)$, compatible with the metric (16) we have chosen on $M_{N \times N}(\mathbb{C})$. The polar decomposition allows us to write down a section $s^R$ for $\mu^R$: if $B$ is in the image of $\mu^R$ (i.e. if $-iB$ is positive semidefinite), simply put

$$s^R(B) = \sqrt{-iB}.$$

The entire pre-image of $B$ under $\mu^R$ is then just the $\mathcal{L}$-orbit $U^p N^q s^R(B)$.

These two items – a section of the moment map and a description of the fibers of $\mu^R$ as $\mathcal{L}$-orbits – are inherited by suitable submonoids of $M_{N \times N}(\mathbb{C})$.

Indeed, we have the following:

**Lemma B.1.** Let $S$ be a sub-monoid of $M_{N \times N}(\mathbb{C})$ given as the closure of a reductive subgroup $H = L_\mathcal{L}$ of $GL(N, \mathbb{C})$, with $L = H \cap U(N)$. Then the fibers of the moment map $\mu^R_L$ for the $\mathcal{R}$-action of $L$ on $S$ are the orbits for the $\mathcal{L}$-action of $L$ (and vice-versa).

**Proof.** Since the $\mathcal{L}$- and $\mathcal{R}$-actions commute we know that any fiber of the moment map for one consists of orbits for the other. Now, since $S$ is a spherical $H \times H$-variety (were we use both $\mathcal{L}$- and $\mathcal{R}$-actions), it follows that symplectically it is a multiplicity-free space for the action of $L \times L$ (see e.g. the discussion in [Kno11, §2]). As a result any fiber of $\Phi_{L \times L}$ (the moment map of the $L \times L$ action composed with the projection to the positive Weyl chamber) consists of a single $L \times L$-orbit. Since $\Phi_{L \times L} = (\Phi^\mathcal{L}_L, \Phi^\mathcal{R}_L)$ and $\Phi^\mathcal{L}_L = \tau \circ \Phi^\mathcal{R}_L$ (where $\tau$ is the involution of the positive Weyl chamber) this implies that any fiber of $\mu^R_L$ is contained in such an $L \times L$-orbit.

On the other hand we know that the fibers of the moment map of the $\mathcal{R}$-action of $U(N)$ on $M_{N \times N}(\mathbb{C})$ are the orbits of the $\mathcal{L}$-action of $U(N)$. It now suffices to remark that, for a point of $S$, the intersection of its $L \times L$-orbit with its $\mathcal{L}$-orbit for $U(N)$ consists exactly of its $\mathcal{L}$-orbit for $L$. \qed

Let us denote the inclusion of $S$ in $M_{N \times N}(\mathbb{C})$ by $\iota$. We can also construct a section of the moment map $\mu^R_L : S \to \mathfrak{l}^* = \text{Lie}(L)^*$, as follows: it is clear that

$$(d\iota)^* \circ \mu^R \circ \iota = \mu^R_L,$$

and we have

**Lemma B.2.** The map

$$(d\iota)^* : (\mu^R \circ \iota)(S) \longrightarrow \mu^R_L(S)$$

is a bijection.
We shall denote the (continuous) inverse of this bijection as $\eta$.

**Proof.** Let $g_1, g_2 \in S$ be such that $\mu^R_L(g_1) = \mu^R_L(g_2)$. Then by Lemma B.1 both belong to the same $L$-orbit of $L$ in $S$, and therefore $\iota(g_1)$ and $\iota(g_2)$ belong to the same $L$-orbit of $U(N)$ in $M_{N \times N}(\mathbb{C})$; this gives $(\mu^R_L \circ \iota)(g_1) = (\mu^R_L \circ \iota)(g_2)$. □

We can put this together with the section $s^R$ of $\mu^R$ as

$$
\begin{array}{c}
S \\
\mu^R_L(S) \\
\mu^R(M_{N \times N}(\mathbb{C})) \\
\mu^R (M_{N \times N}(\mathbb{C})) \\
M_{N \times N}(\mathbb{C}) \\
\end{array}
\begin{array}{c}
\iota \\
\mu^R_L \\
\eta \\
\iota \\
\iota \\
\end{array}
\begin{array}{c}
s^R_L \\
\mu^R \\
\eta \\
s^R \\
\iota^* \\
\end{array}
\begin{array}{c}
\iota^* \\
\iota \\
\iota^* \\
\iota \\
\iota^* \\
\end{array}
\begin{array}{c}
S \\
\mu^R_L(S) \\
\mu^R(M_{N \times N}(\mathbb{C})) \\
M_{N \times N}(\mathbb{C}) \\
\iota^* \\
\end{array}$$

**Lemma B.3.** The composition $s^R_L := s^R \circ \eta$ takes values in $S$, and can therefore be understood as a section of $\mu^R_L$.

**Proof.** By continuity it suffices to check this on $\mu^R_L(H)$. The section $s^R$ is characterized by the fact that the polar decomposition all of its values can be chosen to have trivial unitary part. Now, if an orbit of the $L$-action of $U(N)$ on $GL(N, \mathbb{C})$ meets $H$ (say in an element $h$), then the unique element in this $L$-orbit whose polar decomposition has trivial unitary part has to be contained in $H$ itself. Indeed, use the Cartan decomposition for $H$ to write $h = le^{i\lambda}$. Then clearly also $e^{i\lambda}$ is contained in both the $L$-orbit of $U(N)$ and in $H$. As the Cartan decomposition is preserved by $\iota$, this element will have trivial unitary part for the Cartan decomposition of $GL(N, \mathbb{C})$, as well as for the polar decomposition (since the Cartan decomposition and the polar decomposition coincide for invertible matrices). Hence $s^R_L$ takes values in $S$, and since $\eta$ is a section of $(d\iota)^*$ and $s^R$ is a section of $\mu^R$ it follows from (20) that $s^R_L$ is a section of $\mu^R_L$. □
