Abstract

A computation method of algebraic local cohomology with parameters, associated with zero-dimensional ideal with parameter, is introduced. This computation method gives us in particular a decomposition of the parameter space depending on the structure of algebraic local cohomology classes. This decomposition informs us several properties of input ideals and the output of our algorithm completely describes the multiplicity structure of input ideals. An efficient algorithm for computing a parametric standard basis of a given zero-dimensional ideal, with respect to an arbitrary local term order, is also described as an application of the computation method. The algorithm can always output “reduced” standard basis of a given zero-dimensional ideal, even if the zero-dimensional ideal has parameters.

Key words: standard bases, algebraic local cohomology, multiplicity structure, systems of parametric polynomials

1. Introduction

Local cohomology was introduced by A. Grothendieck in \cite{Grothendieck}. Subsequent development to a great extent has been motivated by Grothendieck’s ideas.

Nowadays, local cohomology is a key ingredient in algebraic geometry, commutative algebra, topology and D-modules, and is a fundamental tool for applications in several fields.

In (Tajima et al., 2009), we proposed, with Y. Nakamura, an algorithmic method to compute algebraic local cohomology classes, supported at a point, associated with a given zero-dimensional ideal. We described therein an efficient method for computing standard bases of zero-dimensional ideals, that utilize algebraic local cohomology classes. The underlying idea of the proposed method comes from the fact that algebraic local cohomology classes can completely describe the multiplicity structure of a zero-dimensional ideal via the Grothendieck local duality theorem. More recently in our result of ISSAC2014 (Nabeshima and Tajima, 2014), we considered the Jacobi ideal, with deformation parameter, of a semi-quasihomogeneous hypersurface isolated singularity. By adopting the same approach presented in Tajima et al. (2009), we constructed an algorithm for computing algebraic local cohomology classes, with parameters, that are annihilated by the Jacobi ideal. As an application, we obtained a new method to compute parametric standard bases of Jacobi ideals associated with a deformation of semi-quasihomogeneous hypersurface isolated singularities.

In this paper, we address the problem of finding an effective method to treat algebraic local cohomology classes with parameters associated with a given zero-dimensional ideal with parameters, that works in general cases.

In order to state precisely the problem, let $X$ be an open neighborhood of the origin $O$ of the $n$-dimensional complex space $\mathbb{C}^n$ with coordinates $x = (x_1, x_2, \ldots, x_n)$. We assume that a set $F$ of $p$ polynomials $f_1, f_2, \ldots, f_p$ in $(\mathbb{C}[t_1, \ldots, t_m])[x]$ satisfying generically $\{a \in X | f_1(a) = \cdots = f_p(a) = 0\} = \{O\}$ are given where $t_1, \ldots, t_m$ are parameters. Let $H_F$ be a set of algebraic local cohomology classes supported at the origin that are annihilated by the ideal generated by $F$. Then $H_F$ is a finite-dimensional vector space if and only if the ideal $\langle F \rangle$ generated by $F$ is zero-dimensional in the rings of formal power series. In such cases, there is a possibility that $\{a \in X | f_1(a) = \cdots = f_p(a) = 0\} \neq \{O\}$ (the same meaning is that $\langle F \rangle$ is not zero-dimensional) for some values of parameters, because of parameters. As our aim is to construct algorithms for studying the structure of $H_F$ and the multiplicity structure of $\langle F \rangle$ on $X$, it is necessary, beforehand if possible, to detect these values of parameters, that constitute constructible sets, from the parameter space for computing algebraic local cohomology classes.

In the first part of this paper, we introduce a new notion of parametric local cohomology system as an analogue of comprehensive system to deal with parametric problems. We describe a new effective method to compute parametric local cohomology systems. The resulting algorithms compute in particular a suitable decomposition of parameter space to a finite set of constructible sets according to the structure of algebraic local cohomology classes in question. The key of the algorithm for decomposing is the use of a comprehensive Gröbner bases computation in a polynomial ring with parameters. The algorithms for computing bases of $H_F$, is designed as dynamic algorithm in consideration of computational efficiency. The output of our algorithm, has the abundant information of the input ideal and provides a complete description of the multiplicity structures of parametric zero-dimensional ideals.

In the second part of this paper, we describe algorithms for computing parametric standard bases as an application of parametric local cohomology systems. We show that
the use of algebraic local cohomology provides an efficient algorithm for computing standard bases. Furthermore, the use of algebraic local cohomology transforms a standard basis of a dimensional ideal $\langle F \rangle$ with respect to any given local term order into a standard basis with respect to any other ordering, without computing the standard basis, again. In general, the computation complexity of standard bases, is strongly influenced by the term order, like Gröbner bases computation. Thus, this property is useful to compute a standard basis.

Especially, our algorithm can output always “reduced” standard basis of a given zero-dimensional ideal, even if $F$ has parameters. Note that, an algorithm implemented in the computer algebra system Singular (Decker, W. et al., 2012) that compute standard bases does not enjoy this property. Moreover, in general, comprehensive Gröbner basis (Nabeshima, 2012; Weispfenning, V., 1992) in a polynomial ring does not have this property, too.

As we mentioned above, there are several applications of algebraic local cohomology. For examples, our algorithm can be used to analyze properties of singularities and deformations of Artin algebra (Iarrobino and Emsalem, 1978; Iarrobino, 1984). It is a powerful tool to study several problems relevant to zero-dimensional ideals.

All algorithms in this paper, have been implemented in the computer algebra system Risa/Asir (Noro and Takeshima, 1992).

This paper is organized as follows. Section 2 briefly reviews algebraic local cohomology, and gives notations and definitions used in this paper. Section 3 is the discussion of the new algorithm for algebraic local cohomology classes with parameters. This section is the main part of this paper. Section 4 gives algorithms for computing parametric standard bases for a given zero-dimensional ideals.

2. Preliminaries

In this section, first we briefly review algebraic local cohomology. Second, we introduce a term order for computing algebraic local cohomology classes and algebraically constructible sets, which will be exploited several times in this paper. Throughout this paper, we use the notation $x$ as the abbreviation of $n$ variables $x_1, \ldots, x_n$. The set of natural number $\mathbb{N}$ includes zero. $K$ is the field of rational numbers $\mathbb{Q}$ or the field of complex numbers $\mathbb{C}$.

2.1. Algebraic local cohomology

Let $H^n_{\mathcal{O}}(K[x])$ denote the set of algebraic local cohomology classes supported at the origin $\mathcal{O}$ with coefficients in $K$, defined by

$$H^n_{\mathcal{O}}(K[x]) := \lim_{k \to \infty} \text{Ext}^n_{K[x]}(K[x]/\langle x_1, x_2, \ldots, x_n \rangle^k, K[x])$$

where $\langle x_1, x_2, \ldots, x_n \rangle$ is the maximal ideal generated by $x_1, x_2, \ldots, x_n$.

Let $X$ be a neighborhood of the origin $\mathcal{O}$ of $K^n$. Consider the pair $(X, X - \mathcal{O})$ and its relative Čech covering. Then, any section of $H^n_{\mathcal{O}}(K[x])$ can be represented as an element of relative Čech cohomology. We use the notation $\sum c_{\lambda} \left[ \frac{1}{x^{\lambda + r}} \right]$ for representing
an algebraic local cohomology class in \( H^n_{(q)}(K[x]) \) where \( c_\alpha \in K \), \( x^{\lambda+1} = x_1^{\lambda_1+1}x_2^{\lambda_2+1} \ldots x_n^{\lambda_n+1} \) with \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_n) \in \mathbb{N}^n \). Note that the multiplication is defined as

\[
x^\alpha \left[ \frac{1}{x^{\lambda+1}} \right] := \begin{cases} 
1, & \lambda_i \geq \alpha_i, i = 1, \ldots, n, \\
0, & \text{otherwise},
\end{cases}
\]

where \( \alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{N}^n \) and \( \lambda + 1 - \alpha = (\lambda_1 + 1 - \alpha_1, \ldots, \lambda_n + 1 - \alpha_n) \).

We represent an algebraic local cohomology class \( \sum c_\alpha \frac{1}{x^{\lambda+1}} \) as a polynomial in \( n \) variables \( \sum c_\lambda \xi^\lambda \) to manipulate algebraic local cohomology classes efficiently (on computer), where \( \xi \) is the abbreviation of \( n \) variables \( \xi_1, \xi_2, \ldots, \xi_n \). We call this representation “polynomial representation”. For example, let \( \psi = \frac{4}{x_1^{\lambda_1}} + \frac{5}{x_2^{\lambda_2}} \) be an algebraic local cohomology class where \( x_1, x_2 \) are variables. Then, the polynomial representation of \( \psi \), is \( 4\xi_1^3\xi_2^2 + 5\xi_1^2\xi_2^3 \) where variables \( \xi_1, \xi_2 \) are corresponding to variables \( x_1, x_2 \).

We use the notation \( \psi = \sum c_\lambda \xi_1^{\lambda_1} \xi_2^{\lambda_2} \ldots \xi_n^{\lambda_n} \) and there exists \( i, j \) so that \( \lambda_i = \lambda_j \) for \( i < j \) and \( \lambda_i < \lambda_j \) where \( |\lambda| = \sum_{i=1}^n \lambda_i \). In general, this term order is called a total degree lexicographic term order.

For a given algebraic local cohomology class \( \psi \) of the form, \( \psi = c_\lambda \xi^\lambda + \sum_{\lambda' \prec \lambda} c_{\lambda'} \xi^{\lambda'} \), \( c_\lambda \neq 0 \), we call \( \xi^\lambda \) the head term and \( \xi^{\lambda'} \), \( \lambda' \prec \lambda \) the lower terms. We denote the head term of a cohomology class \( \psi \) by \( \text{ht}(\psi) \).

2.2. Strata and specialization

We use the notation \( t \) as the abbreviation of \( m \) variables \( t_1, \ldots, t_m \). (One can also regard \( t \) as parameters.) Let \( K \) be an algebraic closure field of \( K \). For \( g_1, \ldots, g_q \in K[t] \),
$\forall (g_1, \ldots, g_l) \subseteq \bar{K}^m$ denotes the affine variety of $g_1, \ldots, g_l$, i.e., $\forall (g_1, \ldots, g_l) := \{ \bar{a} \in \bar{K}^m \mid g_1(\bar{a}) = \cdots = g_l(\bar{a}) = 0 \}$ and $\forall (0) := \bar{K}^m$.

We use an algebraically constructive set that has a form $\forall (g_1, \ldots, g_l) \setminus \forall (g'_1, \ldots, g'_{l'})$, where $g_1, \ldots, g_l, g'_1, \ldots, g'_{l'} \in K[t]$. We call the form $\forall (g_1, \ldots, g_l) \setminus \forall (g'_1, \ldots, g'_{l'})$ a stratum. (Notation $\mathcal{A}, \mathcal{A}', \mathcal{A}_1, \ldots, \mathcal{A}_k$ are frequently used to represent strata.)

When we treat with systems of parametric equations, then it is necessary to check consistency of their parametric consistent. In several papers [Kapur et al. 2010; Montes, 2002; Suzuki, A., and Sato, Y. 2003], algorithms for checking consistency have been already introduced. Thus, it is possible to decide whether $\forall (Q_1) \setminus \forall (Q_2)$ is an empty set or not, by these algorithms where $Q_1, Q_2 \subset K[t]$. The details are in the papers.

We define the localization of $K[t]$ w.r.t. a stratum $\mathcal{A} \subseteq \bar{K}^m$ as follows: $K[t]_{\mathcal{A}} = \{ \bar{x} \mid c, b \in K[t], b(t) \neq 0 \text{ for } t \in \mathcal{A} \}$. Then, for every $\bar{a} \in \mathcal{A}$, we can define the canonical specialization homomorphism $\sigma_{\bar{a}} : K[t]_{\mathcal{A}}[x] \to \bar{K}[x]$ (or $\sigma_{\bar{a}} : K[t]_{\mathcal{A}}[\xi] \to \bar{K}[\xi]$). When we say that $\sigma_{\bar{a}}(h)$ makes sense for $h \in K(t)[x]$, it has to be understood that $h \in K[t]_{\mathcal{A}}[x]$ for some $\mathcal{A}$ with $\bar{a} \in \mathcal{A}$. We can regard $\sigma_{\bar{a}}$ as substituting $\bar{a}$ into $m$ variables $t$.

### 3. Algebraic local cohomology with Parameters

Let us assume that a set $F$ of $p$ polynomials $f_1, f_2, \ldots, f_p$ in $(K[t])[x]$ satisfying generically $\{ a \in X \mid f_1(a) = \cdots = f_p(a) = 0 \} = \{ O \}$ are given where $X$ is a neighborhood of the origin $O$ of $\bar{K}^n$. Here, we regard $t$ as parameters, and $x, \xi$ are the main variables.

We define a set $H_F = \cup_{\mathcal{A} \subseteq \bar{K}^m} H_{\sigma_{\bar{a}}(F)}$ to be the set of algebraic local cohomology classes in $K[\xi]$ that are annihilated by the ideal generated by $F$, where

$$H_{\sigma_{\bar{a}}(F)} = \{ \psi \in K[\xi] \mid \sigma_{\bar{a}}(f_1) \ast \psi = \cdots = \sigma_{\bar{a}}(f_p) \ast \psi = 0 \}.$$  

The ideal $\langle F \rangle$ at $\bar{a} \in \bar{K}^m$ is a zero-dimensional ideal if and only if $H_{\sigma_{\bar{a}}(F)}$ is a finite-dimensional vector space. In this section we describe an algorithm for computing bases of the vector space $H_F$. More precisely, we describe algorithms for computing parametric local cohomology systems (see Definition 5 in this section).

The new algorithm consists of the following three parts.

1. Decompose the parameter space $\bar{K}^m$ into safe strata and danger strata.
2. Compute bases of the vector space $H_F$ on safe strata.
3. Compute bases of the vector space $H_F$ on danger strata.

#### 3.1. An algorithm for testing dimensions of a parametric ideal

Since polynomials $f_1, f_2, \ldots, f_p$ have parameters, there is a possibility that $\{ a \in X \mid f_1(a) = \cdots = f_p(a) = 0 \} \neq \{ O \}$. As our aim is to construct algorithms for studying the system $F$ on $X$, it is necessary, beforehand, to take away these values of parameters that constitute constructible sets from the parameter space for computing local cohomology.

Here, we describe an algorithm for decomposing $\bar{K}^m$ into $S = \{ \mathcal{A}_1, \ldots, \mathcal{A}_k \}$ and $D = \{ \mathcal{A}_{k+1}, \ldots, \mathcal{A}_l \}$ where $\langle F \rangle$ is zero-dimensional on $\mathcal{A}_i$ and non-zero-dimensional on $\mathcal{A}_j$ in a polynomial ring, for $1 \leq i \leq k, k + 1 \leq j \leq l$. This decomposition is possible by mainly computing a comprehensive Gröbner system of $F$. We adopt the following definition of comprehensive Gröbner systems, because this definition is suitable to compute dimensions of ideals in the algorithm ZeroDimension. (The following definition is different from the original one).
For any \( g \in R[x] \) and \( GP \subset R[x] \), \( \text{ht}(g) \) (resp. \( \text{hm}(g), \text{hc}(g), \text{mdeg}(g) \)) is the head term (resp. the head monomial, the head coefficient, the multidegree) of a polynomial \( g \) so that \( \text{hm}(g) = \text{hc}(g) \cdot \text{ht}(g) \) and \( \text{ht}(g) = x^{\text{mdeg}(g)} \) hold and \( \text{ht}(GP) = \{\text{ht}(g) | g \in GP \} \) where \( R = K, K[t] \) or \( K(t) \).

**Definition 2** (Comprehensive Gröbner system (CGS)). Let fix a term order. Let \( F \) be a subset of \((K[t])[x], A_1, \ldots, A_l \) strata in \( K^m \) and \( GP_1, \ldots, GP \) subsets of \((K[t])[x] \). A finite set \( \mathcal{G} = \{(A_1, GP_1), \ldots, (A_l, GP_l)\} \) of pairs is called a comprehensive Gröbner system (CGS) on \( A_1 \cup \cdots \cup A_l \) for \( F \) if \( \sigma_a(GP_a) \) is a Gröbner basis of the ideal \( \langle \sigma_a(F) \rangle \) in \( K[x] \) and \( \langle \text{ht}(\sigma_a(GP_a)) \rangle = \langle \text{ht}(GP_a) \rangle \) for each \( a = 1, \ldots, l \) and \( \sigma_a \in A_i \). Each \( \langle \sigma_a(GP_a) \rangle \) is called a segment of \( \mathcal{G} \). We simply say \( \mathcal{G} \) is a comprehensive Gröbner system for \( F \) if \( A_1 \cup \cdots \cup A_l = K^m \).

After obtaining a CGS of \( F \) w.r.t a total degree term order, as each segment of the CGS has the property \( \langle \text{ht}(\sigma_a(GP_a)) \rangle = \langle \text{ht}(GP_a) \rangle \), the dimension of \( \langle GP_a \rangle \) is easily decided in \( K[x] \). Since an algorithm for computing a CGS terminates, the following algorithm clearly terminates.

**Algorithm 1.** (ZeroDimension)

**Specification:** ZeroDimension(\( F \))

Testing dimensions of a parametric ideal \( \langle F \rangle \) on \( K^m \).

**Input:** \( F \): a set of parametric polynomials in \((K[t])[x] \)

**Output:** \( (S, D): S = \{(A_1, GP_1), \ldots, (A_k, GP_k)\} \) is a CGS on \( A_1 \cup \cdots \cup A_k \) for \( F \) s.t. for all \( a \in A_i, \langle \sigma_a(F) \rangle \) is zero-dimensional in \( K[x] \), for each \( i = 1, \ldots, k \). \( D = \{(A_{k+1}, GP_{k+1}), \ldots, (A_k, GP_k)\} \) is a CGS on \( A_{k+1} \cup \cdots \cup A_k \) for \( F \) such that for all \( b \in A_j, \langle \sigma_b(F) \rangle \) is not zero-dimensional in \( K[x] \), for each \( j = k+1, \ldots, l \). \( K^m = A_1 \cup \cdots \cup A_k \cup A_{k+1} \cup \cdots \cup A_l \).

**BEGIN**

\( S \leftarrow \emptyset; D \leftarrow \emptyset; C \leftarrow \text{compute a CGS on } K^m \) of \( F \) w.r.t. a total degree term order

while \( C \neq \emptyset \) do

select \( (A, GP) \) from \( C \); \( C \leftarrow C \setminus \{(A, GP)\}; d \leftarrow \text{compute the dimension of } \langle GP \rangle \) in \( K[x] \)

if \( d = 0 \) then \( S \leftarrow S \cup \{(A, GP)\} \) else \( D \leftarrow D \cup \{(A, GP)\} \) end-if

end-while

return \((S, D)\)

**END**

In our implementation, we adopt Nabeshima’s algorithm [Nabeshima, 2012] for computing comprehensive Gröbner systems, because the algorithm is much more useful than others for computing dimensions of parametric ideals.

**Definition 3.** Using the same notation as in the above algorithm, let \( (S, D) \) be an output of ZeroDimension(\( F \)). Then, for each \( i = 1, \ldots, k, A_i \) is called a safe stratum, and for each \( j = k+1, \ldots, l \), \( A_j \) is called a danger stratum.

**Example 4.** Let \( f = x_1^3 + tx_1^2x_2^2 + x_2^3 \) be a polynomial with a parameter \( t \) in \((C[t])[x_1, x_2] \). A CGS of \( F = \langle \frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2} \rangle \) w.r.t. the total degree reverse lexicographic term order s.t. \( x_1 < x_2 \), is \( \{(V(t), \{x_1^3, x_2^3\}), (V(t-2), \{x_1^3x_2, x_2^4, x_1^3x_1x_2^2\}), (V(t+2), \{x_1^3x_2 - x_2^3, x_1^2 - x_1x_2^2\}), (C \setminus V(t^2 - 4)), \{tx_1^3x_2 + 2x_2^3, 2x_1^3 + tx_1^3x_2, (t^2 - 4)x_1x_2^3, (t^2 - 4)x_2^3\}) \).
If the parameter $t$ belongs to $\mathcal{V}(t)$ or $\mathcal{C}\setminus \mathcal{V}(t^2 - 4)$, then $\left(\frac{\partial f}{\partial y}, \frac{\partial f}{\partial y}\right)$ is zero-dimensional. If the parameter $t$ belongs to $\mathcal{V}(t-2)$ or $\mathcal{V}(t-2)$, then $\left(\frac{\partial f}{\partial y}, \frac{\partial f}{\partial y}\right)$ is one-dimensional. Therefore, $\mathcal{S} = \{(\mathcal{V}(t), \{x_1^3, x_1^3\}), (\mathcal{C}\setminus \mathcal{V}(t^2 - 4)), \{ax_1^2x_2 + 2x_2^2, 2x_2^3 + tx_1x_2^2, (t^2 - 4)x_1x_2^3, (t^2 - 4)x_2^2\}\}$ and $\mathcal{D} = \{(\mathcal{V}(t-2), \{x_1^2x_2 + x_1^2, x_1^3, x_1^3 - x_1x_2^2\}), (\mathcal{V}(t+2), \{x_1^2x_2 - x_2^3, x_1^3 - x_1x_2^2\})\}$. That is, $\mathcal{V}(t), \mathcal{C}\setminus \mathcal{V}(t^2 - 4)$ are safe strata, and $\mathcal{V}(t-2), \mathcal{V}(t+2)$ are danger strata.

Let $(\mathcal{S}, \mathcal{D})$ denote an output of ZeroDimension$(F)$ where $\mathcal{S} = \{(\mathcal{A}_1, \mathcal{P}_1), \ldots, (\mathcal{A}_k, \mathcal{P}_k)\}$ and $\mathcal{D} = \{(\mathcal{A}_{k+1}, \mathcal{P}_{k+1}), \ldots, (\mathcal{A}_l, \mathcal{P}_l)\}$ (notation is from the algorithm ZeroDimension). Since for all $\bar{a} \in \mathcal{A}_1 \cup \cdots \cup \mathcal{A}_k$, $\langle \sigma_\bar{a}(F) \rangle$ is zero-dimensional in $\bar{K}[x]$, $\langle \sigma_\bar{b}(F) \rangle$ is also zero-dimensional in $\bar{F}[[x]]$. However, in general, for all $\bar{b} \in \mathcal{A}_{k+1} \cup \cdots \cup \mathcal{A}_l$, it is not possible for us to say that $\langle \sigma_\bar{b}(F) \rangle$ is not zero-dimensional in $\bar{F}[[x]]$. For some $\bar{b} \in \mathcal{A}_{k+1} \cup \cdots \cup \mathcal{A}_l$, $\langle \sigma_\bar{b}(F) \rangle$ may be zero-dimensional in $\bar{F}[[x]]$.

After decomposing the parameter space $\mathcal{K}^m$ into safe strata and danger strata by the algorithm ZeroDimension, we compute bases of the vector space $H_F$ on safe strata and danger strata, separately. Actually, this decomposition lets us construct an efficient algorithm for computing the bases. (See section 3.3.)

As the set $F$ has parameters, the structure of the vector spaces $H_F$ depends on the values of parameters $t$. Here, we introduce a definition of parametric local cohomology system of $H_F$.

**Definition 5.** Using the same notation as in the above, let $\mathcal{A}_i, \mathcal{B}_i$ strata in $\bar{K}^m$ and $S_i$ a subset of $(K[t]_{\mathcal{A}_i})[\bar{\xi}]$ where $1 \leq i \leq l$ and $1 \leq j \leq k$. Set $\mathcal{S} = \{(\mathcal{A}_1, S_1), \ldots, (\mathcal{A}_l, S_l)\}$ and $\mathcal{D} = \{(\mathcal{B}_1, \ldots, \mathcal{B}_k)\}$. Then, a pair $(\mathcal{S}, \mathcal{D})$ is called a **parametric local cohomology system** of $H_F$ on $\mathcal{A}_1 \cup \cdots \cup \mathcal{A}_k \cup \mathcal{B}_1 \cup \cdots \cup \mathcal{B}_k$, if for all $j \in \{1, \ldots, l\}$ and $\bar{a} \in \mathcal{A}_i$, $\sigma_\bar{a}(S_i)$ is a basis of the vector space $H_{\sigma_\bar{a}(F)}$, and for all $j \in \{1, \ldots, k\}$ and $\bar{b} \in \mathcal{B}_j$, $\{c \in K|\sigma_\bar{b}(f_j) = \cdots = \sigma_\bar{b}(f_p) = 0\} \neq \{O\}$ where $H_{\sigma_\bar{a}(F)} := \{\psi \in \bar{K}[\bar{\xi}] | \sigma_\bar{a}(f_1) * \psi = \sigma_\bar{a}(f_2) * \psi = \cdots = \sigma_\bar{a}(f_p) * \psi = 0\}$.

After here, we represent “a parametric local cohomology system of $H_F$ on $\bar{K}^m$” as simply “$H_F$” which is the abbreviation. Similarly, we call “a parametric local cohomology system of $H_F$ on a stratum $\mathcal{A}$” “**bases of (the vector space) $H_F$ on $\mathcal{A}$**”.

As this section 3 presents thirteen algorithms for computing bases of the vector space $H_F$. Fig. 1 illustrates the relations of the all algorithms. The main algorithm is **ALCohomolog**.

First, we introduce in section 3.2 an algorithm for computing bases of the vector space $H_F$ on safe strata. Second, we describe in section 3.3 an algorithm for computing bases of the vector space $H_F$ on danger strata.

### 3.2. Computation of algebraic local cohomology with parameters on safe strata

Here, we present an algorithm for computing bases of algebraic local cohomology classes $H_F$, on safe strata. This section consists of three parts. In section 3.2.1, an algorithm for computing monomial elements of bases of $H_F$ is introduced. In section 3.2.2 and 3.2.3, an algorithm for treating with elements, which form linear combination ($\sum c_\lambda \xi^\lambda$), of bases of $H_F$, is given.
3.2.1. Monomial elements

Here, we give an algorithm for computing monomial elements of bases of $H_F$. Before describing the algorithm, we define some notation.

**Notation 6.** Let $GP$ be a set of polynomials in $(K[t])[x]$ and $g \in GP$.

1. The set of monomials of $g$ is denoted by $\text{Mono}(g)$, i.e., $\text{Mono}(g) := \{a_\lambda x^\lambda | g = \sum a_\lambda x^\lambda \text{ where } a_\lambda \in K[t] \}$ and $a_\lambda \neq 0\}$. Moreover, the set of monomials of the set $GP$ is denoted by $\text{Mono}(GP)$, i.e., $\text{Mono}(GP) := \bigcup_{g \in GP} \text{Mono}(g)$.

2. For all $i \in \{1, \ldots, n\}$, a map $\mathcal{C}V$ is defined as $\text{Changing Variables } x_i \text{ into } \xi_i$. The inverse map $\mathcal{C}V^{-1}$ is defined as changing variables $\xi_i$ into $x_i$. That is, for any $g \in (K[t])[x]$, $\mathcal{C}V(g)$ is in $(K[t])[\xi]$. The set $\mathcal{C}V(GP)$ is also defined as $\mathcal{C}V(GP) = \{\mathcal{C}V(g) | g \in GP\}$.

For instance, for $\frac{2}{3}x_1^2x_2 + 5x_1, 3x_1^2 + 4x_2 \in K[x_1, x_2]$, then $\mathcal{C}V(\frac{2}{3}x_1^2x_2 + 5x_1) = \frac{2}{3}\xi_1^2\xi_2 + 5\xi_1$ and $\mathcal{C}V(\frac{1}{4}x_1^2x_2 + 5x_1, 3x_1^2 + 4x_2)) = \{\frac{1}{4}\xi_1^2\xi_2 + 5\xi_1, 3\xi_1^2 + 4\xi_2\}$ in $K[\xi_1, \xi_2]$ where variables $\xi_1, \xi_2$ are corresponding to variables $x_1, x_2$.

**Proposition 7.** Let $(S, D)$ be an output of $\text{ZeroDimension}(F)$ and $(\mathbb{A}, GP) \in S$. Assume that $B$ is a CGS of the monomial ideal $\langle \mathcal{C}V(\text{Mono}(GP)) \rangle$ in $(K(t))[\xi]$ on $\mathbb{A}$, and $(\mathbb{A}', G') \in B$. Then, a monic monomial $\psi = \xi_1^{\alpha_1}\xi_2^{\alpha_2} \cdots \xi_n^{\alpha_n}$ which does not belong to $\langle \text{ht}(G') \rangle$, has the property $f_i \ast \psi = 0$ for each $1 \leq i \leq p$. Namely, all terms which do not belong to $\langle \text{ht}(G') \rangle$, are members of bases of $H_F$ on $\mathbb{A}'$.

**Proof.** Let $\psi = \xi_1^{\alpha_1}\xi_2^{\alpha_2} \cdots \xi_n^{\alpha_n}$ be a monomial s.t. $\psi \notin \langle \text{ht}(G') \rangle$. By Definition 2, for all $\bar{a} \in \mathbb{A}'$, $\langle \text{ht}(G') \rangle = \langle \text{ht}(\sigma_{\bar{a}}(G')) \rangle = \langle \mathcal{C}V(\text{Mono}(G')) \rangle$. As $\langle \text{ht}(G') \rangle$ is a zero-dimensional ideal and $\psi \notin \langle \text{ht}(G') \rangle$, for all $\xi_1^{\lambda_1}\xi_2^{\lambda_2} \cdots \xi_n^{\lambda_n} \in \mathcal{C}V(\text{Mono}(F))$, there always exists $j \in \{1, 2, \ldots, n\}$ such that $\lambda_j > \alpha_j$ where $(\alpha_1, \alpha_2, \ldots, \alpha_n), (\lambda_1, \lambda_2, \ldots, \lambda_n) \in \mathbb{N}^n$. Therefore, by the multiplication, $f_i \ast \psi = 0$. □
This proposition gives rise to the following algorithm to compute monomial elements of bases of $H_F$ on $\mathbf{A}$. Since the termination of Nabeshima’s algorithm [Nabeshima, 2012] is guaranteed, the following algorithm terminates.

**Algorithm 2. (MonoSafe)**

**Specification: MonoSafe($\mathbf{A}, GP$)**

Computing monomial elements of bases of $H_F$ on a safe stratum $\mathbf{A}$.

**Input:** ($\mathbf{A}, GP$): a segment of a CGS of $F$ such that for all $\overrightarrow{a} \in \mathbf{A}$, $\langle \sigma_\overrightarrow{a}(F) \rangle$ is zero-dimensional in $\mathbb{K}[x]$. (This is from ZeroDimension($F$).)

**Output:** $\mathcal{M}$: a finite set of triples ($\mathbf{A}', M, G$) such that the set $M$ includes all monomial elements of bases of $H_F$ on $\mathbf{A}'$, and the elements of $M$ do not belong to $\langle G \rangle$.

**BEGIN**

$\mathcal{M} \leftarrow \emptyset$; $B \leftarrow$ compute a CGS of $CV$(Mono($GP$)) on $\mathbf{A}$

while $B \neq \emptyset$ do

select ($\mathbf{A}', G'$) from $B$; $B \leftarrow B \setminus \{\langle \mathbf{A}', G' \rangle\}$; $G \leftarrow \text{ht}(G')$

$M \leftarrow$ compute monomial elements which do not belong to $\langle G \rangle$ in $\mathbb{K}[\xi]$. (*1)

$\mathcal{M} \leftarrow \mathcal{M} \cup \{\langle \mathbf{A}', M, G \rangle\}$

end-while

return $\mathcal{M}$

**END**

Let us remark that as $\langle GP \rangle$ is a zero-dimensional ideal on $\mathbf{A}$, the set $M$ consists of finitely many monomial elements. Note that monomial elements, on danger strata, will be considered in section 3.3.

We illustrate the algorithm MonoSafe with the following example.

**Example 8.** Let $f = x_1^4 + tx_1^2 x_2^2 + x_2^4$ be a polynomial with a parameter $t$ in $(\mathbb{C}[t])[x_1, x_2]$. Set $F = \{ \frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2} \}$. Then, $F$ satisfies generically $\{ a \in X | \frac{\partial f}{\partial x_1}(a) = \frac{\partial f}{\partial x_2}(a) = 0 \} = \{ O \}$ where $X$ is a neighborhood of the origin $O$ of $\mathbb{C}^2$. From Example 4, $(\mathcal{V}(t), \{ x_1^3, x_2^2 \})$ and $(\mathcal{C} \setminus \mathcal{V}(t(t^2 - 4)), \{ tx_1^2 x_2 + 2x_2^3, 2x_1^3 + tx_1 x_2^2, (t^2 - 4)x_1 x_2^3, (t^2 - 4)x_2^5 \})$ can be inputs of the algorithm MonoSafe.

(1) Take $(\mathcal{V}(t), \{ x_1^3, x_2^2 \})$ as an input of the algorithm MonoSafe. Then, a CGS of $CV(\{ x_1^3, x_2^2 \})$ on $\mathcal{V}(t)$, is $(\mathcal{V}(t), \{ \xi_1^3, \xi_2^2 \})$. Set $G_1 = \text{ht}(\{ \xi_3^3, \xi_4^2 \}) = \{ \xi_1^3, \xi_2^2 \}$. Then, all elements of $M_1 = \{ 1, \xi_1, \xi_2, \xi_3^2, \xi_1 \xi_2, \xi_2 \xi_3, \xi_1 \xi_2, \xi_2 \xi_3, \xi_1 \xi_2 \xi_3 \}$ do not belong to $\langle G_1 \rangle$. See $\bullet$ in Fig. 2. $M_1$ can be a subset of bases of $H_F$ on $\mathcal{V}(t)$.

(2) Take $(\mathcal{C} \setminus \mathcal{V}(t(t^2 - 4)), P)$ where $GP = \{ tx_1^2 x_2 + 2x_2^3, 2x_1^3 + tx_1 x_2^2, (t^2 - 4)x_1 x_2^3, (t^2 - 4)x_2^5 \}$. As Mono($GP$) = $\{ tx_1^2, 2x_1^3, 2x_1 x_2^2, (t^2 - 4)x_1 x_2^3, (t^2 - 4)x_2^5 \}$, a CGS of $(\mathcal{CV}(\text{Mono}(GP)))$ on $\mathcal{C} \setminus \mathcal{V}(t(t^2 - 4))$ is $(\mathcal{C} \setminus \mathcal{V}(t(t^2 - 4)), \{ \xi_1^4, \xi_2^3, \xi_1 \xi_2, \xi_2 \xi_3 \})$. Set $G_2 = \text{ht}(\{ \xi_1^6, \xi_1^2 \xi_2, \xi_1 \xi_2^2, \xi_2 \xi_3 \}) = \{ \xi_1^4, \xi_1^2 \xi_2, \xi_1 \xi_2, \xi_2 \xi_3 \}$ and compute monomial elements which do not belong to $\langle G_2 \rangle$. Then, we obtain $M_2 = \{ 1, \xi_1, \xi_2, \xi_3^2, \xi_1 \xi_2, \xi_2 \xi_3 \}$ which can be a subset of bases of $H_F$ on $\mathcal{C} \setminus \mathcal{V}(t(t^2 - 4))$. See $\bullet$ in Fig. 3.
3.2.2. Head terms of linear combination elements and the main algorithm

Here, we illustrate an algorithm for computing bases of $H_F$. Before describing the algorithm, first we treat with elements, which form linear combination ($\sum c_i \xi^i$), of bases of $H_F$. Especially, we discuss how to decide head terms of the linear combination elements ($\sum c_i \xi^i$). Second, an algorithm for computing bases of $H_F$ on safe strata, is given. Note that an algorithm for deciding lower terms, will be described in section 3.2.3.

Let us recall the following lemma which follows from the fact that if $\psi \in H_F$, so is $x_i \ast \psi \in H_F$ for each $i = 1, \ldots, n$. This lemma informs us candidates of head terms in $H_F$.

**Lemma 9** (Tajima and Nakamura (2009)). Let $\Lambda_F$ denote the set of exponents of head terms in $H_F$ and $\lambda = (\lambda_1, \ldots, \lambda_n) \in \mathbb{N}^n$. Let $\Lambda_F^{(\lambda)}$ denote a subset of $\Lambda_F : \Lambda_F = \{\lambda \in \mathbb{N}^n | \exists \psi \in H_F \text{ s.t. } \text{ht}(\psi) = \xi^\lambda\}$ and $\Lambda_F^{(\lambda)} = \{\lambda' \in \Lambda_F | \lambda' < \lambda\}$. If $\lambda \in \Lambda_F$, then, for each $j = 1, 2, \ldots, n, (\lambda_1, \lambda_2, \ldots, \lambda_{j-1}, \lambda_{j} + 1, \lambda_{j+1}, \ldots, \lambda_n)$ is in $\Lambda_F^{(\lambda)}$, provided $\lambda_j \geq 1$.

Let $\xi^\lambda$ be a term where $\lambda = (\lambda_1, \ldots, \lambda_n) \in \mathbb{N}^n$. We call $\xi^\lambda \cdot \xi_i$ a **neighbor** of $\xi^\lambda$ for each $i = 1, \ldots, n$. Then, $|\xi^\lambda \cdot \xi_i| = \sum_{i=1}^n \lambda_i + 1$.

**Notation 10.** Let $T$ be a set of terms in $K[\xi]$. Then, we define the neighbor of $T$ as $\text{Neighbor}(T)$, i.e., $\text{Neighbor}(T) := \{\tau \cdot \xi_i | \tau \in T, i = 1, \ldots, n\}$.

The following corollary is a direct consequence of Lemma 9.

**Corollary 11.** Let $\text{TList}^{(d)} = \{\xi^\lambda | \lambda \in \Lambda_F, |\xi^\lambda| = d\}$. If for all $i \in \{1, \ldots, n\}$, $\tau = \xi_1^{\lambda_1} \cdots \xi_n^{\lambda_n} \in \text{TList}^{(d+1)}$ satisfies $\xi_i | \tau$, then, $\{\tau / \xi_i | \lambda_i \neq 0, i \in \{1, \ldots, n\}\} \subset \text{TList}^{(d)}$ where $(\lambda_1, \ldots, \lambda_n) \in \mathbb{N}^n$.

Let $T$ be a subset of $\text{TList}^{(d)}$. Then, by Corollary 11, there is a possibility that an element of $\text{Neighbor}(T)$ belongs to $\text{TList}^{(d+1)}$. This fact makes up the following algorithm which outputs new candidates for head terms.

**Algorithm 3. (HLem)**

**Specification:** HLem($T$, TList$^{(d)}$)

Making new candidates for head terms from $T$.

**Input:** $T$: a set of terms whose total degree are $d$, and $T \subseteq \text{TList}^{(d)}$.

**Output:** $S$: a set of new candidates whose total degree are $d + 1$. 
BEGIN
S ← ∅; B ← Neighbor(T)
while B ≠ ∅ do
    select τ from B; B ← B \ {τ}
    for i from 1 to n do B ← B \ {τ}
        if ξ_i|τ then
            if τ/ξ_i ∉ TList(d) then Flag ← 0; break end-if
        end-if
    end-for
    if Flag = 1 then S ← S ∪ {τ} end-if
end-while
return S
END

If τ is not in the set of head terms of $H_F$ (written ht($H_F$)), then neighbors of τ are not in ht($H_F$). This means that if τ is not in ht($H_F$), then it is unnecessary to compute elements which are divided by τ, as candidates for head terms. This fact makes up the following notation NonMember. We also give the notation Car and Cdr which are exploited in the some algorithms.

Notation 12. Let $T$ be a set of terms in $K[ξ]$ and τ be the smallest element in $T$ w.r.t. the term order (of Definition 1).

1. Let FL be a set of terms in $K[ξ]$ such that for all $ξ^λ ∈ FL$, λ is not in $Λ_F$ where $Λ_F$ is the set of exponents of head terms in $H_F$. Then, the notation NonMember of $(T,FL)$ is defined by NonMember$(T,FL) := \{ ξ ∈ T | \varphi → ξ$ for all $\varphi ∈ FL \}$.  
2. The notation Car and Cdr for $T$, are defined as follows
   \[ Car(T) := \{ ψ ∈ T | |ψ| = |τ| \} \], \[ Cdr(T) := T \setminus Car(T) \].
3. Suppose that $T^{(d)} = \{ ξ^λ ∈ T | |ξ^λ| = d ∈ \mathbb{N} \}$ and $TT = \{ τ^{(d_1)}, τ^{(d_2)}, \ldots, τ^{(d_u)} \}$ where $d_i ∈ \mathbb{N}$ and $τ^{(d_i)} ≠ ∅$ for each $i = 1, \ldots, u$. Let $d_j$ be the minimal number in $\{d_1, \ldots, d_u\}$. Then, the same notation Car and Cdr are defined, for a set of sets $TT$, as follows
   \[ Car(TT) := τ^{(d_j)}, \quad Cdr(TT) := TT \setminus Car(TT) \].

Let $M$ be an output of MonoSafe$(A, GP)$ where $(A, GP)$ is a segment of a CGS of $F$. Suppose that $(A', M', G')$ is an element of $M$. Remember that all elements of $M'$ do not belong to $⟨G'⟩$. Since clearly $G' ⊂ Neighbor(M')$, elements of $G'$ become candidates of head terms in $H_F$. The use of this property makes candidates of the head terms, efficiently.

Corollary 13. Using the same notation as in the above discussion, Notation 12 and Lemma 9, let $M^{(d)} = \{ ξ^λ ∈ M', |ξ^λ| = d \}$ and $T^{(d)} = TList^{(d)} \setminus M^{(d)}$. Then, elements of $Neighbor(T^{(d)})$ and $G'$ can be candidates of head terms in $H_F$.

Suppose that GList = $\{ G^{(d_1)}, \ldots, G^{(d_u)} \}$ and FL is a set of terms in $K[ξ]$ such that for all $ξ^λ ∈ FL$, λ is not in $Λ_F$ where $G^{(d_j)} = \{ ξ^γ ∈ G' | |ξ^γ| = d_j \}$ and $j ∈ \{1, \ldots, u\}$. Now, we introduce how to obtain a set of candidates of head terms in $H_F$ from $T^{(d)}$ and GList. In order to make the set of the candidates, the following four cases are considered.
Case (i) \( T^{(d)} = \emptyset \land \text{GList} = \emptyset \). Case (ii) \( T^{(d)} = \emptyset \land \text{GList} \neq \emptyset \).
Case (iii) \( T^{(d)} \neq \emptyset \land \text{GList} = \emptyset \). Case (iv) \( T^{(d)} \neq \emptyset \land \text{GList} \neq \emptyset \).

In case (i), our main algorithm terminates, because any candidates of the head terms can not be made by the sets. In case (ii), \text{Car}(\text{GList}) has to be considered as a set of the next candidates w.r.t. the term order. In case (iii), \text{NonMember}(\text{HLem}(T^{(d)}, \text{TList}^{(d)}), \text{FL}) has to be considered as a set of the next candidates whose total degree is \( d+1 \). In case (iv), for any \( \tau \in \text{Car}(\text{GList}) \), if \( |\tau| - d = 1 \), then \text{NonMember}(\text{HLem}(T^{(d)}, \text{TList}^{(d)}), \text{FL}) \cup \text{Car}(\text{GList}) \) has to be considered as a set of the next candidates, otherwise the next candidates is \text{NonMember}(\text{HLem}(T^{(d)}, \text{TList}^{(d)}), \text{FL})

Let us remark that the algorithm \text{BodySafe} decides head terms of bases of \( H_F \), from bottom to up with respect to the term order (total degree lexicographic term order). Therefore, the sets \( T^{(d)} \) and \( \text{TList}^{(d)} \) are already obtained when the following algorithm makes the set of the candidates whose total degree are \( d + 1 \).

\begin{algorithm}
\textbf{Algorithm 4. (HeadCand)}

\textbf{Specification:} \text{HeadCand}(T^{(d)}, \text{GList}, \text{TList}^{(d)}, \text{FL})
Making new candidates for head terms.

\textbf{Input:} \( T^{(d)}, \text{GList}, \text{TList}^{(d)}, \text{FL} \): described above.

\textbf{Output:} \( \text{CT} \): a set of new candidates for head terms (or \text{Car}(\text{GList})). \text{GList}: renewed \text{GList}; \( T^{(d)} \): renewed \( T^{(d)} \).

\textbf{BEGIN}
\begin{verbatim}
if \( T^{(d)} = \emptyset \land \text{GList} = \emptyset \) then /* case (i) */
  \text{CT} \leftarrow \emptyset ; \text{return}(\text{CT}, \text{GList}, T^{(d)})
else if \( T^{(d)} = \emptyset \land \text{GList} \neq \emptyset \) then /* case (ii) */
  \text{CT} \leftarrow \text{Car}(\text{GList}) ; \text{GList} \leftarrow \text{Cdr}(\text{GList}) ; \text{return}(\text{CT}, \text{GList}, T^{(d)})
else if \( T^{(d)} \neq \emptyset \land \text{GList} = \emptyset \) then /* case (iii) */
  \text{CT} \leftarrow \text{NonMember}(\text{HLem}(T^{(d)}, \text{TList}^{(d)}), \text{FL}) ; \ d \leftarrow d + 1 ; \ T^{(d)} \leftarrow \emptyset
  \text{return}(\text{CT}, \text{GList}, T^{(d)})
else if \( T^{(d)} \neq \emptyset \land \text{GList} \neq \emptyset \) then /* case (iv) */
  \ G \leftarrow \text{Car}(\text{GList}) ; \ \text{GL} \leftarrow \text{Cdr}(\text{GList}) ; \text{select } \xi^* \text{ from } G
  \text{if } |\xi^*| - d > 1 \text{ then}
    \text{CT} \leftarrow \text{NonMember}(\text{HLem}(T^{(d)}, \text{TList}^{(d)}), \text{FL}) ; \ d \leftarrow d + 1 ; \ T^{(d)} \leftarrow \emptyset
    \text{return}(\text{CT}, \text{GList}, T^{(d)})
  \text{end-if}
  \text{if } |\xi^*| - d = 1 \text{ then}
    \text{CT} \leftarrow \text{NonMember}(\text{HLem}(T^{(d)}, \text{TList}^{(d)}), \text{FL}) \cup G ; \ \text{GList} \leftarrow \text{GL}
    \text{return}(\text{CT}, \text{GList}, T^{(d)})
  \text{end-if}
\end{verbatim}
\textbf{END}
\end{algorithm}

The algorithm \text{BodySafe} consists of mainly two parts, computing candidates for head terms and lower terms. For each part, the algorithm makes use of sets as intermediate data. As this is a dynamic algorithm, each intermediate data is often renewed in the algorithm. As sets \text{SList}, \text{MList}, \text{LList}, \text{GList}, \text{CT}, \ T^{(d)}, \text{CL} are frequently used in algorithms on a stratum, we fix the meaning of the sets as follows.
Notation 14. SList := \{ \psi \in K(t)[\xi] \mid \psi \text{ is a linear combination element of a basis} \}.
MList := \{ \psi \in K[\xi] \mid \psi \text{ is a monic monomial element of a basis} \}.
LList := \{ \xi^\lambda \in K[\xi] \mid \xi^\lambda \text{ is a lower term of } \psi \text{ where } \psi \in \text{SList} \}.
CT := \{ \tau \in K[\xi] \mid \tau \text{ is a candidate for head terms of a basis} \}.
FL := \{ \tau \in K[\xi] \mid \tau \text{ is a failed candidate for head terms} \}.
GList := \bigcup \{ \{ \xi^\gamma \in G \mid |\xi^\gamma| = d_i \} \} \text{ described in the algorithm HeadCand.}
T^{(d)} := \{ \tau \in K[\xi] \mid \tau \text{ is a head term whose total degree is } d \}.
CL := \{ \xi^\lambda \in K[\xi] \mid \xi^\lambda \text{ is a candidate for lower terms for some } \tau \in \text{CT} \}.

As } F \text{ has parameters, when we compute bases of } H_F \text{ by the main algorithm ALCohomology, the parameter space } K^n \text{ is decomposed to suitable strata for the bases. Hence, on each stratum, the sets above are decided. Note that when the algorithm terminates, then a set SList } \cup \text{ MList becomes a basis of } H_F \text{ on each stratum.}

In the following two algorithms, sets EL, LL, UU, RR are used for algorithmic consistency, to decide lower terms. The sets will be explained in section 3.2.3.

The main algorithm ALCohomology consists of two parts for safe strata and danger strata. The first part an algorithm BodySafe for safe strata, is given in this section. The second part an algorithm BodyDanger for danger strata will be discussed in section 3.3.

Suppose that Q is a list. Then, Q[i] means the ith element of the list Q. For example, let Q = \{A, CT, GList\}, then Q[1] = A, Q[2] = CT and Q[3] = GList. In the following algorithms, lists Q, E and MList^{(d)} = \{ \tau \in \text{MList} \mid |\tau| = d \} play actively.

Algorithm 5. (ALCohomology)

**Specification:** ALCohomology(F, k)
Computing bases of a vector space H_F with parameters.

**Input:** F = \{f_1, \ldots, f_p\}: F \subset (K[t])[x] satisfying generically \{a \in X \mid f_1(a) = \cdots = f_p(a) = 0\} = \{O\} where X is a neighborhood of the origin O of K^n. \nu \in \mathbb{N}: an estimated bound of dimensions of the vector space H_F or a sufficient big number (see section 3.3).

**Output:** (S, D): S is a set of lists \{A, SList, MList, LLList, FL\} where SList } \cup \text{ MList is a basis of } H_F \text{ on } A, \text{ LLList is a set of lower terms of SList and FL is a set of failed candidates for head terms on } A.

**BEGIN**
CT \leftarrow \emptyset; SList \leftarrow \emptyset; LLList \leftarrow \emptyset; FL \leftarrow \emptyset; LL \leftarrow \emptyset; RR \leftarrow \emptyset; EL \leftarrow \emptyset
UU \leftarrow \emptyset; AC \leftarrow \emptyset; DL \leftarrow \emptyset; (Z, \mathcal{N}) \leftarrow \text{ZeroDimension}(F)

/* on safe strata */
while Z \neq \emptyset do
select Z_1 \text{ from } Z; Z \leftarrow \text{Z}\setminus\{Z_1\}; M \leftarrow \text{MonoSafe}(Z_1)
while M \neq \emptyset do
select (A, MList, G) \text{ from } M; M \leftarrow M\setminus\{(A, MList, G)\}
GList \leftarrow \bigcup \{ \{ \xi^\gamma \in G \mid |\xi^\gamma| = d_i \} \}; \tau \leftarrow \text{the smallest element in } G \text{ w.r.t. } \prec; d \leftarrow |\tau|
T^{(d)} \leftarrow \emptyset; Q \leftarrow \{A, CT, GList, T^{(d)}, SList, MList, LLList, FL, LL, EL, RR, UU]
AC \leftarrow AC \cup \{Q\}
end-while
end-while
Coho \leftarrow \text{BodySafe}(AC, F)
/*on danger strata */
while $\mathcal{N} \neq \emptyset$ do
select $N_1$ from $\mathcal{N}$; $\mathcal{N} \leftarrow \mathcal{N}\backslash\{N_1\}$; $\mathcal{M} \leftarrow \text{MonoDanger}(N_1)$
while $\mathcal{M} \neq \emptyset$ do
select $(A, \text{MList}, G)$ from $\mathcal{M}$; $\mathcal{M} \leftarrow \mathcal{M}\backslash\{(A, \text{MList}, G)\}$
if $\text{MList} \neq \emptyset$ then
$\text{GList} \leftarrow \bigcup_i \{\{\xi^* \in G | ||\xi^*|| = d_i\}\}$; $\tau \leftarrow$ the smallest element in $G$ w.r.t. $\prec$; $d \leftarrow |\tau|$
$T^{(d)} \leftarrow \emptyset$; $Q \leftarrow \{A, \text{CT}, \text{GList}, T^{(d)}, \text{SList}, \text{LList}, \text{MList}, \text{FL}, \text{LL}, \text{EL}, \text{RR}, \text{UU}\}$
$\mathcal{D}\mathcal{L} \leftarrow \mathcal{D}\mathcal{L} \cup \{Q\}$
else $D \leftarrow D \cup \{A\}$
end-if
end-while
end-while
$(\text{Co}, D_1) \leftarrow \text{BodyDanger}(\nu, \mathcal{D}\mathcal{L}, F)$
end-while

Algorithm 6. (BodySafe)

**Specification:** BodySafe($\mathcal{A}\mathcal{C}, F$)
Computing bases of algebraic local cohomology $H_F$ for $\mathcal{A}\mathcal{C}$.

**Input:** $\mathcal{A}\mathcal{C}$: a set of lists $[A, \text{CT}, \text{GList}, T^{(d)}, \text{SList}, \text{LList}, \text{MList}, \text{FL}, \text{LL}, \text{EL}, \text{RR}, \text{UU}]$.

**Output:** $S$: a set of lists $[A, \text{SList}, \text{MList}, \text{LList}, \text{FL}]$ where $\text{SList} \cup \text{MList}$ is a basis of $H_F$ on $A$, $\text{LList}$ is a set of lower terms of $\text{SList}$, and $\text{FL}$ is a set of failed candidates for head terms on $A$.

BEGIN
$S \leftarrow \emptyset$
while $\mathcal{A}\mathcal{C} \neq \emptyset$ do
select $\mathcal{E} = [A, \text{CT}, \text{GList}, T^{(d)}, \text{SList}, \text{LList}, \text{MList}, \text{FL}, \text{LL}, \text{EL}, \text{RR}, \text{UU}]$ from $\mathcal{A}\mathcal{C}$
$\mathcal{A}\mathcal{C} \leftarrow \mathcal{A}\mathcal{C} \backslash \{\mathcal{E}\}$
if $\text{CT} \neq \emptyset$ then $\xi^* \leftarrow \text{Car}(\text{CT})$; $\text{CT} \leftarrow \text{Cdr}(\text{CT})$
else $(\text{CT}, \text{GList}, T^{(d)}) \leftarrow \text{HeadCand}(T^{(d)}, \text{GList}, \text{MList}^{(d)} \cup T^{(d)}, \text{FL})$ ($\Diamond 1$)
if $\text{CT} \neq \emptyset$ then $\xi^* \leftarrow \text{Car}(\text{CT})$; $\text{CT} \leftarrow \text{Cdr}(\text{CT})$
else $S \leftarrow S \cup \{[A, \text{SList}, \text{MList}, \text{LList}, \text{FL}]\}$
end-if
end-if

$(\text{CL}, \text{UU}, \text{EL}) \leftarrow \text{LowCand}(\xi^*, \text{SList}, \text{MList}, \text{LList}, \text{LL}, \text{UU}, \text{RR}, \text{EL})$ ($\Diamond 2$)

$Q \leftarrow [\text{CT}, \text{GList}, \text{MList}, \text{UU}]$
$P \leftarrow \text{OneElement}(\xi^*, \text{CL}, A, T^{(d)}, \text{EL}, \text{FL}, \text{SList}, \text{LList}, Q, F)$ ($\Diamond 3$)
$S \leftarrow S \cup \text{BodySafe}($ $P$ $)$
end-while
return $S$
END
The algorithm **BodySafe** consists of three parts (1), (2) and (3). In (1), new candidates for head terms are computed. The part (1) was already described in the beginning of this section. In (2), candidates (CL) of $\xi$'s lower terms are computed. The part (2) will be described in section 3.3. Here, we do not explain the part (2), but by seeing the operation of CL, one can understand the flow of the algorithm **BodySafe**. In (3), an element $\xi + \sum_{\lambda \in CL} c_{\lambda} \xi^\lambda$ is tested whether it can be in $H_F$ or not. That is, linear combination elements are decided in the part (3). Note that in (3), a list $Q$ is not essentially used by the algorithm **OneElement**. The list $Q$ is just used in order to shorten the algorithm. The part (3) is given as follows.

### Algorithm 7. OneElement

**Specification:** **OneElement**($\xi$, CL, A, $T^{(d)}$, EL, FL, SList, LList, Q, $\{f_1, \ldots, f_p\}$)  
Testing whether $\xi + \sum_{\lambda \in CL} c_{\lambda} \xi^\lambda$ is in $H_F$ or not.

**Input:** $\xi$, CL, A, $T^{(d)}$, EL, FL, SList, LList, Q: described in the algorithm **BodySafe**.  
**Output:** $L$: a set of lists [A, CT, GList, $T^{(d)}$, SLList, MList, LList, FL, LL, EL, RR, UU].

**BEGIN**  
$L \leftarrow \emptyset$; $E \leftarrow \emptyset$  
$\psi \leftarrow \text{set } \xi + \sum_{\lambda \in CL} c_{\lambda} \xi^\lambda$ where $c_{\lambda}$'s are indeterminates  
for $i$ from 1 to $p$ do  
    $\psi \leftarrow f_i * \psi$  
    /*check $f_i * \psi = 0$. $f_i * \psi \in (K[t, c_{\lambda}])[\xi]$*/  
    while $\psi \neq 0$ do  
        $E \leftarrow E \cup \{\text{hc}(\psi) = 0\}$;  
        $\psi \leftarrow \psi - \text{hm}(\psi)$  
    end-while  
end-for  

$[(A_1, A_2)] \leftarrow \text{solve the system } E \text{ of parametric linear equations on } A$.  

(*1)

while $A_1 \neq \emptyset$ do  
    select an element $(A', [c_{\lambda}' \text{~s solutions}])$ from $A_1$:  
    $A_1 \leftarrow A_1 \setminus \{(A', [c_{\lambda}' \text{~s solutions}])\}$  
    $\psi' \leftarrow \text{substitute } c_{\lambda}' \text{~s solutions into } \psi$;  
    $\text{SList} \leftarrow \text{SList} \cup \{\psi'\}$;  
    $T^{(d)} \leftarrow T^{(d)} \cup \{\xi\}$  
    $(EL, LL, RR, LList) \leftarrow \text{renew}_\text{low}(1, EL, \psi' - \xi, LList)$  
    $L \leftarrow L \cup \{(A', Q[1], Q[2], T^{(d)}, \text{SList}, Q[3], LList, FL, LL, EL, RR, Q[4])\}$  
while-end  

while $A_2 \neq \emptyset$ do  
    select an element $A'$ from $A_2$:  
    $A_2 \leftarrow A_2 \setminus \{A'\}$;  
    $FL \leftarrow FL \cup \{\xi\}$  
    $(EL, LL, RR, LList) \leftarrow \text{renew}_\text{low}(0, EL, \xi, LList)$  
    $L \leftarrow L \cup \{(A', Q[1], Q[2], T^{(d)}, \text{SList}, Q[3], LList, FL, LL, EL, RR, Q[4])\}$  
while-end  

return $L$

**END**  

If $\psi = \xi + \sum_{\xi \in CL} c_{\lambda} \xi^\lambda$ is in $H_F$, then $\psi$ satisfies conditions $f_i \ast \psi = 0$ for each $i = 1, \ldots, p$. These conditions give us a set $E$ of $c_{\lambda}$'s linear equations. Thus, by solving the system $E$, we know whether $\psi$ is in $H_F$ or not. Namely, if solutions of $c_{\lambda}$'s exist, then $\psi \in H_F$, and if the solutions of $c_{\lambda}$'s do not exist, then $\psi \notin H_F$.

Let us remark that as the system of equations $E$ has parameters, the stratum $A$ has to be decomposed into suitable strata for the solutions. For instance, let $t$ be a parameter and $x, y$ be variables. Consider a system “$tx + y = 4, 3x + 2y = -9$” of parametric linear equations on $\mathbb{C} \setminus \mathbb{V}(t)$. Then, the system has the following solutions; if the parameter
\( t \) belongs to \( \mathbb{C} \setminus \mathcal{V}(t(3t + 4)(2t - 3)) \), then \( x = \frac{-17}{2t^3}, y = \frac{-9t - 12}{2t^3} \), if the parameter \( t \)
belongs to \( \mathcal{V}(3t + 4) \), then \( x = -3, y = 0 \), and if a parameter \( t \) belongs to \( \mathcal{V}(2t - 3) \), then \( E \) has no solution. There exist several algorithms for solving a system of parametric linear equations (Gao and Chou, 1992; Sit, 1992). In our implementation, we extend the Gaussian elimination method to handle parametric cases.

In the box (**1) of the algorithm **OneElement, \( A_1 \) means a set of pairs \((A', \{c_\lambda \text{'s solutions}\})\) and \( A_2 \) means a set of strata such that for any stratum of \( A_2 \), the system has no solution. The algorithm **OneElement** has a subalgorithm **renew\_low** which computes candidates of lower terms of \( \xi^g \) and is given in section 3.2.3.

**Theorem 15.** The first part of the algorithm **ALCohomology** (i.e., **BodySafe**) terminates and outputs a set \( \text{Coho} \) which has a list \([\bar{\alpha}, \text{SList}, \text{MList}, \text{LList}, \text{FL}]\) such that \( \text{SList} \cup \text{MList} \) is a basis of \( H_F \) on \( \bar{\alpha} \).

**Proof.** The algorithms **LowCand** and **renew\_low** are considered in section 3.2.3. and the termination and correctness are discussed in section 3.2.3. In the algorithm **ZeroDimension**, the parameter space \( \hat{K}^m \) is decomposed to a finite number of strata. As we described, in the algorithm **OneElement**, an algorithm for solving the system of parametric equations, outputs a finite number of strata (Gao and Chou, 1992; Sit, 1992). Since the algorithm **BodySafe** works on safe strata, \((F)\) is zero-dimensional on the strata. This means that \( H_F \) is a finite-dimensional vector space (Tajima and Nakamura, 2009; Tajima et al., 2009). Therefore, the first part of the algorithm **ALCohomology** (i.e., **BodySafe**) generates a finite number of strata. Thus, the algorithm terminates. Moreover, clearly all elements of \( \text{SList} \cup \text{MList} \) are linearly independent on \( \bar{\alpha} \), \( \text{SList} \cup \text{MList} \) is a basis of \( H_F \) on \( \bar{\alpha} \).

**Example 16.** Let \( f = x_1^3 + tx_1^2 x_2 + x_2^3 \in (\mathbb{C}[t])[x_1, x_2] \). Set \( F = \{ \frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2}\} \). Then, \( F \)
satisfies generically \( \{a \in X| \frac{\partial f}{\partial x_1}(a) = \frac{\partial f}{\partial x_2}(a) = 0\} = \{O\} \) where \( X \) is a neighborhood of the origin \( O \) of \( \mathbb{C}^2 \). The term order is the total degree lexicographic term order such that \( \xi_1 < \xi_2 \).

\[ (0) \quad \text{CT} = \emptyset, \text{SList} = \emptyset, \text{FL} = \emptyset. \]

**Case (1):** From Example 8, the output of **MonoSafe**(\( \mathcal{V}(t), \{x_1^3, x_2^3\} \)) is \( (\mathcal{V}(t), \text{MList}, G_1) \) where \( \text{MList} = \{1, \xi_1, \xi_2, \xi_1^2, \xi_1^2 \xi_2, \xi_1 \xi_2, \xi_1 \xi_2^2, \xi_1^2 \xi_2^2\} \) and \( G_1 = \{\xi_1^3, \xi_2^3\} \). Then, \( \text{GList} = \{\{\xi_1^3, \xi_2^3\}\} \) and the smallest element in \( G_1 \) is \( \xi_1^3 \). Since \( |\xi_1^3| = 3 \), set \( T^{(3)} = \emptyset \).

\[ (1-1) \text{ As } T^{(3)} = \emptyset, \text{GList} = \{\{\xi_1^3, \xi_2^3\}\} \text{ and } \text{CT} = \emptyset, \text{CT} \text{ and } \text{GList} \text{ are renewed as } \text{CT} = \text{Car}(\text{GList}) = \{\xi_1^3, \xi_2^3\} \text{ and } \text{GList} = \emptyset. \text{ So, } \text{Car} (\text{CT}) = \xi_1^3 \text{ and } \text{CT} = \text{Cdr}(\text{CT}) = \{\xi_2^3\}. \text{ Then, the algorithm **LowCand** outputs the empty set as the set of candidates of } \xi_2^3 \text{'s lower terms. This means that there is no candidate for lower terms of } \xi_1. \text{ Since } \frac{\partial f}{\partial x_1} \ast \xi_1^3 = 4, \frac{\partial f}{\partial x_2} \ast \xi_1^3 = 0, \text{ we obtain equations } 4 = 0 \text{ and } 0 = 0. \]

Clearly, \( 4 = 0 \) is false. Hence, \( \xi_1^3 \) can not be a member of \( H_F \). Renew FL as \( \{\xi_1^3\} \).

\[ (1-2) \text{ As } \text{CT} = \{\xi_2^3\}, \text{ the new candidate for head terms is } \xi_2^3. \text{ Renew CT as } \text{Cdr}(\text{CT}) = \emptyset. \]

Then, the algorithm **LowCand** outputs \( \{\xi_1^3\} \) as the set of candidates for lower terms. Set \( \xi_2^3 + c_{(3,0)} \xi_1^4 \) where \( c_{(3,0)} \) is an indeterminate. Since \( \frac{\partial f}{\partial x_1} \ast \{\xi_2^3 + c_{(3,0)} \xi_1^4\} = 4c_{(3,0)}, \frac{\partial f}{\partial x_2} \ast \{\xi_2^3 + c_{(3,0)} \xi_1^4\} = 4, \text{ we obtain equations } 4c_{(3,0)} = 0 \text{ and } 4 = 0. \text{ Clearly, } 4 = 0 \text{ is false. Hence, } \xi_2^3 \text{ can not be a head term in } H_F. \text{ Renew FL as } \{\xi_1^3, \xi_2^3\}. \text{ This process terminates, because } \text{CT} = \text{GList} = \emptyset. \]
Case (2): From Example 8, the output of MonoSafe(C \ V(t^2 - 4)), \{tx^2x_z + 2x^3, 2x^3 + txz^2, (t^2 - 4)x_z^2, (t^2 - 4)x_z^2\}, is (C \ V(t^2 - 4)), MLList, G_2) where MLList = \{1, ξ_1, ξ_2, ξ_4, ξ_1, ξ_2, ξ_3\} and G_2 = \{ξ_1, ξ_2, ξ_1, ξ_2, ξ_3, ξ_2\}. Then, GLList = \{\{ξ_1, ξ_2, ξ_3, ξ_1, ξ_2, ξ_3\}\} and the smallest element in G_2 is ξ_3. Since |ξ_3| = 3, set T^(3) = \∅.

(2-1) As T^(3) = \∅, GLList \neq \∅ and CT = \∅, CT and GLList are renewed as CT = Car(GLList) = \{ξ_1, ξ_2, ξ_3\} and GLList = \∅. So, Car(CT) = ξ_1 and CT = Cdr(CT) = \{ξ_1, ξ_2, ξ_3\}. By the same reasoning as in (1-1), ξ_1 can not be a member of H_F. Renew FL as \{ξ_4\}.

(2-2) As CT = \{ξ_1, ξ_2, ξ_3\}, the new candidate of a head term in H_F, is ξ_1. Renew CT as Cdr(CT) = \{ξ_4\}. Then, the algorithm LowCand outputs \{ξ_1\} as the set of candidates of ξ_3^3ξ_3^3ξ_3^3ξ_3^3\’s lower terms. Set ξ_3^3ξ_3^3ξ_3^3ξ_3^3 + c_{(3,0)}ξ_3^3 is an indeterminate. Since \( \frac{df}{dx^1} * (ξ_3^3ξ_3^3ξ_3^3ξ_3^3) = 4c_{(3,0)}, \frac{df}{dx^2} * (ξ_3^3ξ_3^3ξ_3^3ξ_3^3) = 2t \), a system of equations is “4c_{(3,0)} = 0, 2t = 0”. As we work on the stratum C \ V(t^2 - 4), 2t = 0 is false. Hence, ξ_3^3ξ_3^3ξ_3^3ξ_3^3 can not be a head term in H_F. FL = \{ξ_1\} ∪ \{ξ_2^3ξ_3^3\} = \{ξ_1, ξ_2, ξ_3\}.

(2-3) As CT = \{ξ_1, ξ_2, ξ_3\}, the next candidate is ξ_3^3ξ_3^3ξ_3^3. Renew CT as Cdr(CT) = \{ξ_4\}. Then, the algorithm LowCand outputs \{ξ_1, ξ_2, ξ_3\} as the set of candidates of ξ_3^3ξ_3^3ξ_3^3ξ_3^3\’s lower terms. Set ps = ξ_3^3ξ_3^3ξ_3^3 + c_{(2,1)}ξ_3^3ξ_3^3ξ_3^3ξ_3^3 + c_{(3,0)}ξ_3^3 where c_{(2,1)}, c_{(3,0)} are indeterminates. Since \( \frac{df}{dx^1} * ps = 4c_{(3,0)} + 2t, \frac{df}{dx^2} * ps = 2tc_{(2,1)} \), a system of equations is “4c_{(3,0)} + 2t = 0, 2tc_{(2,1)} = 0”. So the linear equations, then c_{(3,0)} = \frac{-2}{t} and c_{(2,1)} = 0. Hence, ξ_3^3ξ_3^3ξ_3^3ξ_3^3 - \frac{2}{t}ξ_3^3 is a member of a basis of H_F on C \ V(t^2 - 4). Thus, SLList = \{ξ_1, ξ_2, ξ_3\}, T^(3) = \{ξ_1, ξ_2\}.

(2-4) As CT = \{ξ_3\}, the next candidate is ξ_3^3ξ_3^3ξ_3^3ξ_3^3. Renew CT as Cdr(CT) = \{ξ_4\}. Then, the algorithm LowCand outputs \{ξ_1, ξ_2, ξ_3\} as the set of candidates of ξ_3^3ξ_3^3ξ_3^3ξ_3^3\’s lower terms. Set ps = ξ_3^3ξ_3^3ξ_3^3ξ_3^3 + c_{(2,1)}ξ_3^3ξ_3^3ξ_3^3ξ_3^3 + c_{(3,0)}ξ_3^3 where c_{(2,1)}, c_{(3,0)} are indeterminates. Since \( \frac{df}{dx^1} * ps = 4c_{(3,0)} + 2t, \frac{df}{dx^2} * ps = 2tc_{(2,1)} + 4 \), a system of equations is “4c_{(3,0)} + 2t = 0, 2tc_{(2,1)} = 0”. So the linear equations, then c_{(3,0)} = 0 and c_{(2,1)} = \frac{-4}{t}.

Hence, ξ_3^3 - \frac{4}{t}ξ_3^3ξ_3^3ξ_3^3ξ_3^3 is a member of a basis of H_F on C \ V(t^2 - 4). Thus, SLList = \{ξ_1, ξ_2, ξ_3\}, T^(3) = \{ξ_3\}. Now, as CT = \∅, the set CT should be renewed by the algorithm HeadCand. Since Neighbor(T^(3)) = \{ξ_3\} and ξ_3^3ξ_3^3ξ_3^3ξ_3^3 can not be in CT. Therefore, the renewed CT is \{ξ_1, ξ_2, ξ_3\}.

(2-5) As CT = \{ξ_1, ξ_2, ξ_3\}, the next candidate is ξ_3^3ξ_3^3ξ_3^3ξ_3^3. Renew CT as Cdr(CT) = \{ξ_4\}. Then, the algorithm LowCand outputs \{ξ_1, ξ_2, ξ_3\} as the set of candidates of ξ_3^3ξ_3^3ξ_3^3ξ_3^3\’s lower terms. Set ps = ξ_3^3ξ_3^3ξ_3^3ξ_3^3 + c_{(2,1)}ξ_3^3ξ_3^3ξ_3^3ξ_3^3 + c_{(3,0)}ξ_3^3 where c_{(2,1)}, c_{(3,0)} are indeterminates. Since \( \frac{df}{dx^1} * ps = (4c_{(4,0)} + 2tc_{(2,2)})ξ_1 + (4c_{(3,1)} + 2t)ξ_2 + 4c_{(3,0)}, \frac{df}{dx^2} * ps = (2tc_{(3,1)} + 4)ξ_1 + 2tc_{(2,2)}ξ_2 + 2tc_{(2,1)}, \) if ψ is in H_F, then ψ satisfies the conditions \( \frac{df}{dx^1} * p = 0, \frac{df}{dx^2} * p = 0 \). Hence, we have to check the five equations 4c_{(4,0)} + 2tc_{(2,2)} = 0, 4c_{(3,1)} + 2t = 0, 2tc_{(3,1)} + 4 = 0, 2tc_{(2,2)} = 0, 2tc_{(2,1)} = 0 on C \ V(t^2 - 4). The two equations 4c_{(4,0)} + 2t = 0 and 2tc_{(3,1)} + 4 = 0 hold only if t = ±2. Therefore, ψ can not be in H_F. FL = \{ξ_1, ξ_2\} ∪ \{ξ_3\} = \{ξ_1, ξ_2, ξ_3\}.

(2-6) The next candidate is ξ_3^3ξ_3^3 and CT = \∅. The algorithm LowCand outputs \{ξ_1, ξ_2, ξ_3\} as the set of candidates of ξ_3^3ξ_3^3\’s lower terms. Set ps = ξ_3^3 + c_{(3,1)}ξ_3^3ξ_3^3 + c_{(2,2)}ξ_3^3ξ_3^3 + c_{(3,1)}ξ_3^3ξ_3^3 + c_{(4,0)}ξ_3^3 + c_{(2,1)}ξ_3^3ξ_3^3 + c_{(3,0)}ξ_3^3 where c_{(1,3)}, c_{(3,1)},
\[ c_{(4,0)}, c_{(2,1)}, c_{(3,0)} \text{ are indeterminates.} \]

\[
\frac{\partial F}{\partial x_1} \ast \psi = (2tc_{(1,3)} + 2tc_{(2,2)} + 4c_{(4,0)})\xi_1 + 4c_{(3,1)}\xi_2 + 4c_{(3,0)}, \quad \frac{\partial F}{\partial x_2} \ast \psi = (4c_{(3,2)} + 2tc_{(3,1)})\xi_1 + (2tc_{(2,2)} + 4)c_{(4,0)}\xi_2 + 2tc_{(2,1)}. \]

Hence, we have to check the system of equations: 
\[ 2tc_{(1,3)} + 2tc_{(2,2)} + 4c_{(4,0)} = 0, \quad 4c_{(3,1)} = 0, \quad 4c_{(3,2)} + 2tc_{(3,1)} = 0, \quad 2tc_{(2,2)} + 4 = 0, \quad 2tc_{(2,1)} = 0. \]

Then, the solution is: 
\[ c_{(1,3)} = 0, c_{(2,2)} = 1, c_{(4,0)} = 1, c_{(2,1)} = 0, c_{(3,0)} = 0. \]

Hence, \( \xi_1^2 - \frac{1}{2}\xi_1^3\xi_2 + \xi_1^4 \) is a member of a basis of \( H_F \) on \( \mathbb{C} \setminus V(t(t^2 - 4)) \). Thus, 
\[
\text{SList} = \{ \xi_1\xi_2^2 - \frac{2}{3}\xi_1^3\xi_2, \xi_1^2\xi_2, \xi_1^3, \xi_1^4 \}, \quad \text{T}^{(4)} = \{ \xi_2^4 \}. \]

As \( \text{CT} = 0, \text{CT} \) can be renewed as \( \{ \xi_2^5 \} \).

(2-7) The next candidate is \( \xi_2^5 \) and \( \text{CT} = 0 \). The algorithm \textbf{LowCand} outputs \( \{ \xi_1^3, \xi_1^4, \xi_1^5, \xi_1^6, \xi_2^1, \xi_2^2, \xi_2^3, \xi_2^4 \} \) as the set of candidates of \( \xi_2^5 \)’s lower terms. Set \( \psi = \xi_2^5 + \frac{c(5,0)}{c(1,2)} + \frac{c(2,2)}{c(1,2)} + \frac{c(3,1)}{c(1,2)} + \frac{c(4,0)}{c(1,2)} + \frac{c(2,1)}{c(1,2)} + \frac{c(3,0)}{c(1,2)} \) where \( c(1,2) = 1, c(2,2) = 1, c(3,1) = 1, c(4,0) = 1, c(2,1) = 1, c(3,0) = 0 \) are indeterminates. In this case, there is no solution that satisfies the conditions \( \frac{\partial F}{\partial x_1} \ast \psi = 0 \) and \( \frac{\partial F}{\partial x_2} \ast \psi = 0 \). \( \text{FL} = \{ \xi_1^3, \xi_1^4, \xi_2^1, \xi_2^2, \xi_2^3, \xi_2^4 \} \). As \( \text{CT} = \text{GList} = 0, \) this process terminates.

We summarize the results as follows:

- If a parameter \( t \) belongs to \( V(t) \) (i.e., \( t = 0 \)), \( \{ 1, \xi_1, \xi_2, \xi_1^2, \xi_1^3, \xi_1^4, \xi_2^1, \xi_2^2, \xi_1\xi_2, \xi_1^2\xi_2, \xi_1^3\xi_2, \xi_2^2 \} \) is a basis of \( H_F \) (algebraic local cohomology classes).
- If a parameter \( t \) belongs to \( \mathbb{C} \setminus V(t(t^2 - 4)) \) (i.e., \( t \neq 0, t \neq \pm 2 \)), then \( \{ 1, \xi_1, \xi_2, \xi_1^2, \xi_1^3, \xi_1^4, \xi_2^1, \xi_2^2, \xi_1\xi_2, \xi_1^2\xi_2, \xi_1^3\xi_2, \xi_2^2 \} \) is a basis of \( H_F \).

In Fig. 4 and 5, we represent an element of MList as \( \bullet \) and an element of \( \text{ht}(\text{SList}) \) as \( \Delta \). Note that on each stratum, a basis of \( H_F \) is \( \text{MList} \cup \text{SList} \). As the set \( \text{FL} \) plays a key role to construct standard bases (see section 4), we specially give the elements of \( \text{FL} \) in the Figures.

3.2.3. Lower terms of linear combination elements

The aim of this section is to construct subalgorithms “\textbf{LowCand}” and “\textbf{renew\_low}” which are in the algorithms “\textbf{BodySafe}” and “\textbf{OneElement}”. Here, we discuss how to compute candidates of lower terms. The ideal for computing the candidates efficiently, is to use the information of the intermediate data SList, MList, LList, FL. Before describing the algorithms, we introduce the following useful lemma.

**Lemma 17.** (Tajima and Nakamura (2009)). Using the same notation as in Lemma 9, let \( \Delta_F \) denote the set of exponents of lower terms in \( H_F \) and \( \Delta_F^{(A)} \) denote a subset of
$\Delta_F : \Delta_F^{(\lambda)} = \{ \lambda' \in \Delta_F | \lambda' \prec \lambda \}$. If $\lambda \in \Delta_F$, then, for each $j = 1, 2, \ldots, n, (\lambda_1, \lambda_2, \ldots, 
abla_j - 1, \lambda_j - 1, \lambda_{j+1}, \ldots, \lambda_n)$ is in $\Delta_F^{(\lambda)} \cup \Delta_F^{(\lambda)}$, provided $\lambda_j \geq 1$.

The algorithm BodySafe computes linear combination elements of a basis of $H_F$ from bottom to up with respect to the term order. The next corollary shows a relation between the indeterminate data “SList, MList, LList” and new candidates of lower terms.

**Corollary 18.** Let $\lambda = (\lambda_1, \ldots, \lambda_n) \in \mathbb{N}^n$ and let SList, MList, LList be indeterminate data in the algorithm BodySafe. If $\xi^\lambda \in \text{LList}$, then, for each $j = 1, 2, \ldots, n$, the term $\xi^\lambda / \xi^i$ is in $\text{ht}(\text{SList}) \cup \text{MList} \cup \text{LList}$, provided $\lambda_j \geq 1$. Conversely, an element of Neighbor(\text{ht}(\text{SList}) \cup \text{MList} \cup \text{LList}) becomes a candidate for lower terms.

This corollary leads us to construct the following algorithm which is essentially same as the algorithm Hlem.

**Algorithm 8. (Llem)**

**Specification:** Llem(Ne, SList, MList, LList)  
Making candidates for lower terms from Ne.  
**Input:** Ne: a set of terms.  
**Output:** S: a set of new candidates for lower terms. 

**BEGIN**  
S ← ∅  
while Ne ̸= ∅ do  
select $\tau$ from Ne; Ne ← Ne\{τ\}  
for $i$ from 1 to $n$ do  
Flag ← 1  
if $\xi^i | \tau$ then  
if $\tau / \xi^i \notin \text{ht}(\text{SList}) \cup \text{MList} \cup \text{LList}$ then Flag ← 0; break  
end-if  
end-if  
end-for  
if Flag = 1 then S ← S ∪ \{τ\} end-if  
end-while  
return S  
**END**

Let us remark that if a lower term is in $\text{ht}(\text{SList}) \cup \text{MList}$, then the lower term can be reduced by elements of SList $\cup$ MList. Namely, LList obtained, becomes always a part of candidates for lower terms. Thus, a set of the candidates is

\[ \text{CL} = \{ \text{proper new candidates of lower terms} \} \cup \text{LList}. \]

As sets EL, LL, RR, UU are frequently used in the algorithms LowCand and re-new_low on a stratum, we fix the meaning of the sets as follows.

**Notation 19.** EL := \{ $\xi^\lambda \in K[\xi] | \xi^\lambda$ is a new candidate for lower terms. $\xi^\lambda \notin \text{LList}$ \}.  
LL := \{ $\xi^\lambda | \xi^\lambda$ is a proper new lower term which belong to EL \}.  
RR := EL \setminus LL.  
UU := \{ $\xi^\beta \in \text{Neighbor}(\text{LL}) | \xi^\gamma \prec \xi^\beta$, for some $\xi^\gamma \in \text{CT}$ \}.  
Note that a set EL $\cup$ LList becomes a set of candidates for lower terms.
As LL is a set of new lower terms, by Corollary 18, elements of \textbf{Neighbor}(LL) become candidates of lower terms. Furthermore, elements of \{\xi^\alpha | \xi^\alpha \prec \xi^\gamma, \xi^\alpha \in \text{UU}\} also become candidates of lower terms where \xi^\gamma is a candidate of a head term.

\begin{algorithm}
\textbf{Algorithm 9. (LowCand)}
\begin{flushleft}
\textbf{Specification:} \text{LowCand}(\xi^\gamma, \text{SList}, \text{MList}, \text{LList}, \text{LL}, \text{UU}, \text{RR}, \text{EL})
\end{flushleft}
\begin{flushleft}
Making candidates for lower terms of \xi^\gamma.
\end{flushleft}
\begin{flushleft}
\textbf{Input:} \xi^\gamma, \text{SList}, \text{MList}, \text{LList}, \text{LL}, \text{UU}, \text{RR}, \text{EL}: described in BodySafe.
\end{flushleft}
\begin{flushleft}
\textbf{Output:} (CL, UU, EL): elements of CL are candidates for \xi^\gamma’s lower terms. UU is a renewed set. EL is a renewed set.
\end{flushleft}
\begin{flushleft}
\textbf{BEGIN}
\begin{flushleft}
U \leftarrow \{\xi^\alpha | \xi^\alpha \prec \xi^\gamma, \xi^\alpha \in \text{UU}\}
\end{flushleft}
\begin{flushleft}
if LL = \emptyset then
\begin{flushleft}
LU \leftarrow \text{LLem}(U, \text{SList}, \text{MList}, \text{LList}); \text{UU} \leftarrow \text{UU} \setminus U
\end{flushleft}
\begin{flushleft}
EL \leftarrow \text{EL} \setminus \text{LU}; CL \leftarrow \text{LList} \cup \text{EL}
\end{flushleft}
\begin{flushleft}
return (CL, UU, EL)
\end{flushleft}
\end{flushleft}
\begin{flushleft}
else /* make EL, UU from RR, LL */
\begin{flushleft}
UU \leftarrow (\text{UU} \setminus U) \setminus \{\xi^\gamma\}; RR \leftarrow U \cup RR
\end{flushleft}
\begin{flushleft}
B \leftarrow \{\beta | \xi^\gamma \prec \xi^\beta, \beta \in \text{Neighbor}(\text{LL})\}; \text{UU} \leftarrow B \cup UU
\end{flushleft}
\begin{flushleft}
D \leftarrow \text{LLem}(\text{Neighbor}(\text{LL}) \setminus B, \text{SList}, \text{MList}, \text{LList})
\end{flushleft}
\begin{flushleft}
EL \leftarrow (D \setminus (D \cap \text{RR})) \cup \text{RR}; CL \leftarrow \text{EL} \cup \text{LList}
\end{flushleft}
\begin{flushleft}
return (CL, UU, EL)
\end{flushleft}
\end{flushleft}
\end{flushleft}
\textbf{END}
\end{algorithm}

Since the algorithm \textbf{OneElement} is dynamic, each intermediate data of \text{EL}, \text{LL}, \text{RR} and \text{LList}, is often renewed in the algorithm. If a system of linear equations has solutions (i.e., \(Z = 1\) in \textbf{renew}_\text{low}), then the proper new lower terms appear as \text{LL}. If a system of linear equations does not have any solution (i.e., \(Z = 0\) in \textbf{renew}_\text{low}), then the candidate of a head term becomes a candidate of lower terms because the candidate is always in \text{Neighbor}(ht(\text{SList}) \cup \text{MList} \cup \text{LList}). This observation makes the algorithm \textbf{renew}_\text{low}.

\begin{algorithm}
\textbf{Algorithm 10. (renew}_\text{low}\textbf{)}
\begin{flushleft}
\textbf{Specification:} \text{renew}_\text{low}(Z, \text{EL}, \psi, \text{LList})
\end{flushleft}
\begin{flushleft}
Renewing the sets \text{EL}, \text{LL} and \text{RR}.
\end{flushleft}
\begin{flushleft}
\textbf{Input:} Z: 0 or 1. \psi: a polynomial.
\end{flushleft}
\begin{flushleft}
\textbf{Output:} (\text{EL}, \text{LL}, \text{RR}, \text{LList}): renewed sets \text{EL}, \text{LL}, \text{RR}, \text{LList}.
\end{flushleft}
\begin{flushleft}
\textbf{BEGIN}
\begin{flushleft}
if \(Z = 0\) then \text{LL} \leftarrow \emptyset; \text{EL} \leftarrow \text{EL} \cup \{\psi\}; \text{RR} \leftarrow \emptyset
\end{flushleft}
\begin{flushleft}
else \text{LL} \leftarrow \text{ht}((\text{Mono}(\psi)) \cap \text{EL}); \text{LList} \leftarrow \text{LList} \cup \text{LL}
\end{flushleft}
\begin{flushleft}
if \text{LL} \neq \emptyset then \text{RR} \leftarrow \text{EL} \setminus \text{LL}; \text{EL} \leftarrow \emptyset
\end{flushleft}
\end{flushleft}
\textbf{END}
\end{algorithm}
Example 20. Let us consider Example 16, again. Here, we show the process for computing candidates for lower terms according to the algorithms LowCand and renew_low. Since a set of candidates for lower terms is CL, we mainly observe the set CL.

(0) LList = ∅, LL = ∅, RR = ∅, EL = ∅, UU = ∅.

Case (1): First, we start to discuss how to compute CL on V(t).

(1-1) Take ξ₁ as a candidate of a head term. The algorithm LowCand outputs the empty set as CL. By the algorithm renew_low, the set EL is renewed as {ξ₁}.

(1-2) Take ξ₂ as a candidate of a head term. According to the algorithm LowCand, CL = EL ∪ LList = {ξ₁}. In Example 16, ξ₂ can not be a head term in H_F. Hence, EL is renewed as {ξ₁, ξ₂}.

Case (2): Second, we discuss how to compute the set CL on C² \ V(t² – 4).

(2-1) Take ξ₁ as a candidate of a head term. The algorithm LowCand outputs the empty set as CL. By the algorithm renew_low, the set EL is renewed as {ξ₁}.

(2-2) Take ξ₁ξ₂ as a candidate of a head term. According to the algorithm LowCand, CL = EL ∪ LList = {ξ₁}. In Example 16, ξ₂ can not be a head term in H_F. Hence, EL is renewed as {ξ₁, ξ₂}.

(2-3) Take ξ₁ξ₂ as a candidate of a head term. According to the algorithm LowCand, CL = EL ∪ LList = {ξ₁, ξ₁ξ₂}. In Example 16, ξ₁ξ₂ is in H_F. By the algorithm renew_low, LL = {ξ₁}, LList = {ξ₁}, RR = EL \ LL = {ξ₁ξ₂} and CL is renewed as the empty set.

(2-4) Take ξ₂ as a candidate of a head term. Then, as Neighbor(LL) = {ξ₁, ξ₁ξ₂} and ξ₂ < ξ₁, ξ₂ < ξ₁ξ₂, we obtain UU = {ξ₁, ξ₁ξ₂} and EL = ∅ ∪ RR = {ξ₁ξ₂}. Hence, CL = EL ∪ LL = {ξ₁, ξ₁ξ₂}. Since ξ₂ < ξ₁ξ₂ and ξ₂ is in H_F by Example 16, then LL = {ξ₁ξ₂}, LList = {ξ₁, ξ₁ξ₂} and RR = EL \ LL = ∅.

(2-5) Take ξ₁ξ₂ as a candidate of a head term. Then, as Neighbor(LL) = {ξ₁, ξ₁ξ₂} and ξ₁ξ₂ < ξ₁, ξ₁ξ₂ < ξ₁ξ₂, we obtain D = {ξ₁ξ₂, ξ₁ξ₂}. Moreover, U = {ξ₁, ξ₁ξ₂}. UU is renewed as {ξ₁, ξ₁ξ₂} \ U = ∅ and RR is renewed as U \ UU = {ξ₁, ξ₁ξ₂}. As D ∩ RR = {ξ₁, ξ₁ξ₂}, EL = D ∪ RR = {ξ₁, ξ₁ξ₂, ξ₁ξ₂} and CL = EL ∪ LL = {ξ₁, ξ₁ξ₂, ξ₁, ξ₁ξ₂, ξ₁ξ₂}. Since ξ₁ξ₂ can not be a head term in H_F by Example 16, the set EL is renewed as EL \ {ξ₁, ξ₁ξ₂} = {ξ₁, ξ₁ξ₂, ξ₁ξ₂, ξ₁ξ₂}.

(2-6) Take ξ₂ as a candidate of a head term. By the algorithm LowCand, CL = EL ∪ LL = {ξ₁, ξ₁ξ₂, ξ₁, ξ₁ξ₂, ξ₁ξ₂, ξ₁ξ₂}. In Example 16, ξ₂ < ξ₁ξ₂ + ξ₁ is in H_F. By the algorithm renew_low, LL = {ξ₁, ξ₁ξ₂}, LList = {ξ₁, ξ₁ξ₂, ξ₁, ξ₁ξ₂}, RR = EL \ LL = {ξ₁ξ₂, ξ₁ξ₂} and EL is renewed as the empty set.

(2-7) Take ξ₂ as a candidate of a head term. Then, as Neighbor(LL) = {ξ₁, ξ₁ξ₂, ξ₁ξ₂, ξ₁ξ₂, ξ₁ξ₂} and ξ₁ξ₂ < ξ₁, ξ₁ξ₂ < ξ₁ξ₂, ξ₁ξ₂ < ξ₁ξ₂, EL = {ξ₁, ξ₁ξ₂, ξ₁ξ₂, ξ₁ξ₂} and CL is renewed as the empty set.

3.3. On danger strata

Here, we present an algorithm for computing bases of algebraic local cohomology classes H_F, on danger strata. Basically, we follow the first part of the main algorithm ALCohomology for danger strata. However, we can not directly follow it, because the termination of the algorithms MonoSafe and BodySafe, is not guaranteed beforehand. If ⟨GP⟩ is not a zero-dimensional ideal in (∗1) of MonoSafe, then a number of elements which do not belong to ⟨G⟩, may not be finite. In such a case, the algorithm does not terminate, and this means that ⟨F⟩ is not a zero-dimensional ideal in K[[x]]. In order
to resolve this matter, the following algorithm for danger strata is introduced instead of the algorithm **MonoSafe**. The termination of following algorithm is guaranteed by the same reason of the algorithm **MonoSafe**.

### Algorithm 11. (MonoDanger)

**Specification:** MonoDanger(\(\mathbb{A}, GP\))

Computing monomial elements of bases of \(H_F\) on a danger stratum \(\mathbb{A}\).

**Input:** \((\mathbb{A}, GP)\): a segment of a CGS of \(F\) s.t. for all \(\bar{a} \in \mathbb{A}\), \(\langle \sigma_{\bar{a}}(F) \rangle\) is non-zero-dimensional in \(K[x]\).

**Output:** \(M\) : a finite set of triples \((\mathbb{A}', M, G)\) where \(M, G \subset K[\xi]\). If \(\langle G \rangle\) is zero-dimensional in \(K[\xi]\), then the set \(M\) is MList of \(H_F\) on \(\mathbb{A}'\), otherwise, \(M = \emptyset\).

**BEGIN**

\[ M \leftarrow \emptyset; \quad B \leftarrow \text{compute a CGS of Mono(CV}(GP)) \text{ on } \mathbb{A} \text{ in } K[\xi] \]

while \(B \neq \emptyset\) do

select \((\mathbb{A}', GP')\) from \(B\); \(B \leftarrow B \setminus \{(\mathbb{A}', GP')\}; \quad G \leftarrow \text{ht}(GP')\)

if \(\dim(\langle G \rangle) = 0\) in \(K[\xi]\) then

\[ M \leftarrow \text{compute monomial elements which do not belong to } \langle G \rangle \]

\[ M \leftarrow M \cup \{(\mathbb{A}', M, G)\} \]

else

\[ M \leftarrow M \cup \{(\mathbb{A}', \emptyset, G)\} \]

end-if

end-while

**END**

The termination of the algorithm **BodySafe** is also a matter of grave concern on danger strata. We have two ideas to resolve this matter.

The first idea is preparing a natural number \(\nu\) which is an estimated bound of a dimension of the vector space \(H_F\). In many cases, a natural number \(\nu\) can be computed from the input \(F\). For instance, if \(f\) is a Newton non-degenerate polynomial defining an isolated singularity at the origin \(O\), a bound of the dimension \(H_F\) can be computed by the Kouchnirenko formula \([\text{Kouchnirenko}, 1976]\), where \(F = \{\frac{\partial f}{\partial x_1}, \ldots, \frac{\partial f}{\partial x_n}\}\). If a number of elements of MList \(\cup\) SList is bigger than and equal to \(\nu\), then \(\langle F \rangle\) is not zero-dimensional.

Otherwise, \(\langle F \rangle\) is zero-dimensional in \(K[[x]]\).

After deciding the number \(\nu\), we can compute bases of algebraic local cohomology \(H_F\) on danger strata as follows.

We name the same name (**BodyDanger**) to both Algorithm 12 and 13. By one’s strategy, one can select one of them.

### Algorithm 12. (BodyDanger) the first idea

**Specification:** BodyDanger(\(\nu, DL, F\))

Computing bases of a vector space \(H_F\) on danger strata

**Input:** \(DL\): a set of lists \(((\mathbb{A}, CT, GList, T^{(d)}, SLList, MLList, LLList, FL, LL, EL, RR, UU))\), \(\nu\): a natural number (an estimated bound).

**Output:** \((S, D)\): \(S = \bigcup_i \{[\mathbb{A}_i, SLList_i, MLList_i, FL_i]\} \) where \(SLList_i \cup MLList_i\) is a basis of \(H_F\) on \(\mathbb{A}_i\), and \(FL_i\) is a set of failed candidates for head terms on \(\mathbb{A}_i\). \(D\) is a set of stratum.

On a stratum of \(D\), \(F\) does not satisfy \(\{a \in X | f_1(a) = \cdots = f_p(a) = 0\} = \{O\}\).

**BEGIN**
\[ S \leftarrow \emptyset; \ \mathcal{D} \leftarrow \emptyset \]

while \( \mathcal{D} \mathcal{L} \neq \emptyset \) do

select \( \mathcal{E} = \{A, \text{CT}, \text{GList}, T^{(d)}, \text{SList}, \text{MList}, \text{LList}, \text{FL}, \text{LL}, \text{EL}, \text{RR}, \text{UU}\} \) from \( \mathcal{D} \mathcal{L} \)

\( \mathcal{D} \mathcal{L} \leftarrow \mathcal{D} \mathcal{L} \setminus \{E\} \)

\( N \leftarrow \) a number of elements of \( \text{SList} \cup \text{MList} \)

if \( k \geq N \) then

\((\Diamond 1)\) of \text{BodySafe}\n
\((\diamondsuit 2)\) of \text{BodySafe}\n
\((\diamondsuit 3)\) of \text{BodySafe}\n
\((S_1, D_1) \leftarrow \text{BodyDanger}(\nu, \mathcal{P}, F); \ S \leftarrow S \cup \{S_1\}; \ D \leftarrow D \cup \{D_1\}\n
end-if

while-end

return \((S, D)\)

END

The second ideal is the following. Let \( m \) be the maximal ideal at the origin \( O \) (i.e., \( m = \langle x_1, \ldots, x_n \rangle \)) and \( \nu \) be a sufficient big positive integer. Then, \( F_{m(\nu)} = \langle F \rangle + m^{(\nu)} \) is an ideal supported at the origin \( O \) where \( m^{(\nu)} = \langle x_1^{\nu}, x_2^{\nu}, \ldots, x_n^{\nu} \rangle \). Therefore, bases of the vector space \( H_{F_{m(\nu)}} \) can be computed by the algorithm \text{BodySafe}. If \( H_{F_{m(\nu)}} = H_{F_{m(\nu+1)}} \) on a stratum \( A \), it is obvious that \( \langle F \rangle = F_{m(\nu)} \) on \( A \). That is, if there exists \( \nu \in \mathbb{N} \) such that \( H_{F_{m(\nu)}} = H_{F_{m(\nu+1)}} \) on \( A \), then \( \langle F \rangle \) is zero-dimensional on \( A \). If \( H_{F_{m(\nu)}} \neq H_{F_{m(\nu+1)}} \) on \( A \), there exist some local cohomology classes in a basis of \( H_{F_{m(\nu)}} \) such that the local cohomology classes do not belong to \( H_{F_{m(\nu+1)}} \). By analyzing such local cohomology classes, we can easily guess and prove that \( H_{F} \) has infinite many (systematic) elements which are linearly independent, on \( A \). That is, in this case, \( \langle F \rangle \) is not zero-dimensional on \( A \).

\textbf{Algorithm 13.} (\text{BodyDanger}) the second idea

\textbf{Specification:} \text{BodyDanger}(\nu, \mathcal{D} \mathcal{L}, \{f_1, \ldots, f_p\})

\text{Computing bases of a vector space } H_{F} \text{ on danger strata}

\textbf{Input:} \( \mathcal{D} \mathcal{L} \): a set of lists \( \{[A, \text{CT}, \text{GList}, T^{(d)}, \text{SList}, \text{MList}, \text{LList}, \text{FL}, \text{LL}, \text{EL}, \text{RR}, \text{UU}]\} \), \( \nu \): a natural number (a sufficient big number).

\textbf{Output:} \( (S, D): S = \bigcup_i \{[A_i, \text{SList}_i, \text{MList}_i, \text{FL}_i]\} \) where \( \text{SList}_i \cup \text{MList}_i \) is a basis of \( H_F \) on \( A_i \) and \( \text{FL}_i \) is a set of failed candidates for head terms on \( A_i \). \( D \) is a set of stratum. On a stratum of \( D \), \( F \) does not satisfy \( \{a \in X \mid f_1(a) = \cdots = f_p(a) = 0\} = \{O\} \).

\text{BEGIN}

\( D \leftarrow \emptyset; \ F_{m(\nu)} \leftarrow \{f_1, \ldots, f_p, x_1^{\nu}, x_2^{\nu}, \ldots, x_n^{\nu}\}; \ F_{m(\nu+1)} \leftarrow \{f_1, \ldots, f_p, x_1^{\nu+1}, x_2^{\nu+1}, \ldots, x_n^{\nu+1}\}\n
\mathcal{H}_1 \leftarrow \text{SafeBody}(\mathcal{D} \mathcal{L}, F_{m(\nu)}); \ \mathcal{H}_2 \leftarrow \text{SafeBody}(\mathcal{D} \mathcal{L}, F_{m(\nu+1)}); \ S \leftarrow \mathcal{H}_1 \cap \mathcal{H}_2; \ D_1 \leftarrow \mathcal{H}_1 \setminus S\n
while \( D_1 \neq \emptyset \) do

select \( \mathcal{E} = [A', \text{SList}', \text{MList}', \text{FL}'] \) from \( \mathcal{D}_1 \); \( \mathcal{D}_1 \leftarrow \mathcal{D}_1 \setminus \{\mathcal{E}\}; \ D \leftarrow D \cup \{A'\}\n
end-while

return \((S, D)\)

END

We illustrate the second idea with the following example.
Example 21. Let us consider Example 4, again. The term order is the total degree lexicographic term order such that $\xi_1 \prec \xi_2$. If the parameter $t$ belongs to $\mathbb{V}(t-2)$ or $\mathbb{V}(t+2)$, the ideal $\langle F \rangle$ is not zero-dimensional in $K[x]$. Set $\nu = 4$ and $F_{m(4)} = \{ \frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2}, x_1^4, x_2^4 \}$ and $F_{m(5)} = \{ \frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2}, x_1^5, x_2^5 \}$. We apply the algorithm BodySafe for $\{ [V(t-2), CT, \{ \xi_1^2 \xi_2, \xi_1^2 \xi_2, \xi_1^2 \xi_2, \xi_1^2 \xi_2 \}], T \}$, SLList, MList, LList, LL, FL, EL, RR, UU $\}$ with $F_{m(4)}$, $F_{m(5)}$, where CT, T, SLList, MList, LList, LL, FL, EL, RR, UU are empty sets. Then, a set $G_1 = \{ 1, \xi_2, \xi_1, \xi_2, \xi_1 \xi_2, \xi_1^2 \xi_2 - \xi_1 \xi_2, \xi_2^2 - \xi_1 \xi_2, \xi_1 \xi_2 - \xi_1 \xi_2, \xi_1 \xi_2 - \xi_1 \xi_2 \}$ is a basis of the vector space $H_{F_{m(4)}}$, a set $G_2 = \{ 1, \xi_2, \xi_1, \xi_2, \xi_1 \xi_2, \xi_1^2 \xi_2 - \xi_1 \xi_2, \xi_2^2 - \xi_1 \xi_2, \xi_1 \xi_2 - \xi_1 \xi_2, \xi_1 \xi_2 - \xi_1 \xi_2 \}$ is a basis of the vector space $H_{F_{m(5)}}$ and $G_1 \neq G_2$.

Our implementation can compute bases of $H_{F_{m(6)}}$ and of $H_{F_{m(7)}}$, too. One can find some systematic elements based on a certain rule from these bases, and guess that the following four sets
\[
\{ \sum_{i=0}^{k/2} (-1)^i \xi_1^{k-2i} \xi_2^i | k = 2n + 4, n \in \mathbb{N} \}, \{ \sum_{i=0}^{k/2} (-1)^i \xi_1^{k-2i} \xi_2^i | k = 2n + 4, n \in \mathbb{N} \},
\{ \sum_{i=0}^{k/2} (-1)^i \xi_1^{k-2i} \xi_2^i | k = 2n + 4, n \in \mathbb{N} \}, \{ \sum_{i=0}^{k/2} (-1)^i \xi_1^{k-2i} \xi_2^i | k = 2n + 4, n \in \mathbb{N} \},
\]
are included in a basis of $H_F$ on $\mathbb{V}(t-2)$. This can be easily proved. Therefore, $\langle F \rangle$ is not zero-dimensional on $\mathbb{V}(t-2)$. One can also easily verify the non-zero-dimensionality of $\langle F \rangle$ on $\mathbb{V}(t+2)$.

In Fig. 6, we represent an monomial element of $H_F$ as $\bullet$ and an elements of head terms of the systematic elements as $\triangle$.

Example 22. Let $f_1 = x_1^2 + x_2^3 + s x_1 x_3 + t x_2 x_3^2$, $f_2 = x_1^3 + x_3^3$. It is described in [Aleksandrov, 1983] that $f_1 = f_2 = 0$ defines a quasi-homogeneous complete intersection isolated singularity provided that the parameters $s, t$ do not belong to $\mathbb{V}((s+t)^3+(s+1)^3)$ and the Milnor number is equal to 16.

Let $f_3 = 3x_2^2 x_3^2 + 2sx_2 x_3^3 + x_1 x_3^2 - sx_1^2 - 2tx_2 x_3$, $f_4 = x_1 x_2 x_3$, $f_5 = x_1 x_2^2$, and set $F = \{ f_1, f_2, f_3, f_4, f_5 \}$. Since $f_1, f_2$ are quasi-homogeneous, a result of [Greuel, G.-M., 1978] on Milnor number and the Grothendieck local duality theorem ([Grothendieck, 1967]) imply that $H_F$ is a vector space of dimension 16 provided $f_1 = f_2 = 0$ has an isolated singularity at the origin. However, the algorithm ZeroDimension outputs $\mathbb{V}(s-t-1) \setminus \mathbb{V}(t^3 + 2t^2 + 2t + 1, s-t-1)$ as a danger stratum and BodyDanger (our implementation) judges $\{ a \in X | f_1(a) = f_2(a) = \cdots = f_5(a) = 0 \} \neq \{ 0 \}$ on the stratum. One can check the fact $\mathbb{V}(s-t-1) \setminus \mathbb{V}(t^3 + 2t^2 + 2t + 1, s-t-1) \subseteq \mathbb{V}((s+t)^3+(s+1)^3)$. For instance, take $(s, t) = \left( \frac{1}{2}, -\frac{1}{2} \right) \in \mathbb{V}(s-t-1) \setminus \mathbb{V}(t^3 + 2t^2 + 2t + 1, s-t-1)$, then $\left( \frac{1}{2}, -\frac{1}{2} \right) \not\in \mathbb{V}((s+t)^3+(s+1)^3)$ and $\{ a \in X | \sigma_{(\frac{1}{2}, -\frac{1}{2})}(f_1(a) = \cdots = \sigma_{(\frac{1}{2}, -\frac{1}{2})}(f_5)(a) = 0 \} \neq \{ 0 \}$.

The algorithm BodyDanger works powerfully to find strata on which $\{ a \in X | f_1(a) = \cdots = f_p(a) = 0 \} \neq \{ 0 \}$.

24
We conclude this section by briefly discussing the effectiveness of the proposed method. In order to detect unnecessary strata on which \( F \) is not zero-dimensional in \( K[[x]] \), first, the algorithm \textbf{ZeroDimension} decomposes the parameter space \( \mathring{K}^m \) into safe strata and danger strata. If there exist danger strata, second, the algorithm \textbf{BodyDanger} detects unnecessary strata. After that if there still exist undeterminable strata, finally, the algorithm \textbf{BodyDanger} actually computes local cohomology classes of \( H_F \) on the strata. The final step is a practical method for detecting unnecessary strata. Note that if we compute a parametric local cohomology system without the algorithm \textbf{ZeroDimension}, then the algorithm \textbf{BodyDanger} (the general case is the second idea) has to be always performed because all strata of \( \mathring{K}^m \) are regarded as danger. As we described above, \textbf{BodyDanger} actually computes local cohomology classes several times. Thus, in this case, the computational complexity increases. To avoid an increase in computation cost, we have innovated the algorithm \textbf{ZeroDimension}. As we described in Example 22, the algorithm \textbf{ZeroDimension} powerfully helps for checking unnecessary strata, and makes the computational method of a parametric local cohomology system, more effective in computational speed and complexity.

4. Parametric standard bases

Here, we introduce an algorithm for computing parametric standard bases of zero-dimensional ideals by using bases of algebraic local cohomology classes.

**Definition 23** (inverse orders). Let \( \prec \) be a local or global term order. Then, the inverse order \( \prec^{-1} \) of \( \prec \) is defined by \( x^\alpha \prec x^\beta \iff x^\beta \prec^{-1} x^\alpha \).

If \( \prec \) is a global term order (1 is the minimal term), then \( \prec^{-1} \) is the local term order (1 is the maximal term). Conversely, if \( \prec \) is a local term order, then \( \prec^{-1} \) is the global term order.

4.1. Parametric standard bases

**Definition 24.** Let \( F \) be a subset of \((K[t]][[x]], A_i \) a stratum in \( \mathring{K}^m \), \( S_i \) a subset of \( K[t][[x]] \) and \( \prec \) a local term order where 1 \( \leq \) \( i \leq \) \( l \). A finite set \( S \) = \{ \( (A_1, S_1), \ldots, (A_l, S_l) \} \) of pairs is called a \textbf{parametric standard basis} on \( A_1 \cup \cdots \cup A_l \) for \( F \) w.r.t. \( \prec \) if \( \sigma_\alpha(S_i) \) is a standard basis of the ideal \( \langle \sigma_\alpha(F) \rangle \) in \( K[[x]] \) w.r.t. \( \prec \) for each \( i = 1, \ldots, l \) and \( \bar{a} \in A_i \).

Let \( F = \{f_1, \ldots, f_p\} \) be a set of polynomials in \( (K[t]][[x]] \) such that \textbf{generically} \( \{a \in X| f_1(a) = \cdots = f_p(a) = 0\} = \{O\} \) where \( X \) is a neighborhood of the origin \( O \) of \( K^n \). Then, by utilizing the information of bases of \( H_F \), one can obtain parametric standard bases of \( \langle F \rangle \) in \( K(t)[[x]] \).

Let us recall that there is a natural pairing, denote by \( \text{res}_{\langle O \rangle}( , , ) \), between the quotient space \( K[[x]]/\langle P \rangle \) and the vector space \( H_P \) where \( \langle P \rangle \subseteq K[[x]] \) is a zero-dimensional ideal. \[ \text{res}_{\langle O \rangle}( , , ) : K[[x]]/\langle P \rangle \times H_P \rightarrow K. \]

Since the pairing is non-degenerate according to the Grothendieck local duality theorem [Grothendieck 1957], we have the following result.
Lemma 25 (Tajima and Nakamura 2009). Let $P = \{g_1, \ldots, g_d\}$ be a set of polynomials in $K[x]$ such that $\{a \in X \mid g_1(a) = \cdots = g_d(a) = 0\} = \{O\}$. Then, a given formal power series $h \in K[[x]]$ is in the ideal $\langle P \rangle$ if and only if for all $\varphi \in \Psi$, $h$ satisfies $\text{res}_i(h, \varphi) = 0$ where $\Psi$ is a basis of the vector space $H_P$.

One can extend this fact into the parametric cases. The next theorem gives us the relation between bases of $H_F$ and parametric standard bases of $\langle F \rangle$.

Notation 26. Let $\text{SList}$ be a set of polynomials in $(K(t))[\xi]$ and $\text{LList}$ be a set of lower terms of all elements of $\text{SList}$. Suppose that there is no monomial in $\text{SList}$, and $\text{SList}$ has an element whose form is $\xi^\lambda + \sum_{\kappa < \lambda} c_{(\lambda, \kappa)}\xi^\kappa$ where $c_{(\lambda, \kappa)} \in K(t)$. Then, the transfer $\text{SB}_{\text{SList}, \text{LList}}(\xi^\lambda)$ is defined by the following:

$$\begin{cases}
\text{SB}_{\text{SList}, \text{LList}}(\xi^\lambda) = x^\lambda - \sum_{\xi^\kappa \in \text{ht}(\text{SList})} c_{(\kappa, \lambda)}x^\kappa \quad \text{in } K(t)[x] \quad \text{if } \xi^\lambda \in \text{LList}, \\
\text{SB}_{\text{SList}, \text{LList}}(\xi^\lambda) = x^\lambda \quad \text{in } K(t)[x] \quad \text{if } \xi^\lambda \notin \text{LList}.
\end{cases}$$

Let $G$ be a set of terms in $K[\xi]$. Then, the set $\text{SB}_{\text{SList}, \text{LList}}(G)$ is also defined by $\text{SB}_{\text{SList}, \text{LList}}(G) = \{\text{SB}_{\text{SList}, \text{LList}}(\xi^\lambda) \mid \xi^\lambda \in G\}$.

Theorem 27. Let $\prec$ be a global total degree lexicographic term order (Definition 1). Let $(\mathcal{S}, \mathcal{D})$ be an output of $\text{ALCohomology}(F)$ and a list $[\mathcal{A}, \text{SList}, \text{MList}, \text{LList}, \text{FL}]$ is in $\mathcal{S}$. Then, for all $\bar{a} \in \mathcal{A}$, $\sigma_{\bar{a}}(\text{SB}_{\text{SList}, \text{LList}}(\text{FL}))$ is the reduced standard basis of $\langle \sigma_{\bar{a}}(F) \rangle$ w.r.t. $\prec^{-1}$ (the local total degree lexicographic term order), in $\bar{K}[[x]]$. Namely, $\{([\mathcal{A}], \text{SB}_{\text{SList}, \text{LList}}(\text{FL}))\}$ is a parametric standard basis on $\mathcal{A}$ for $F$. (The notation $\sigma$ is from Section 3.1.)

Proof. Since the algorithm $\text{BodySafe}$ decides linear combination elements of a basis of $H_F$ from bottom to up w.r.t. $\prec$ and $(F)$ is zero-dimensional on $\mathcal{A}$, the set $\text{CV}^{-1}(\text{FL})$ (failed candidates of head terms) becomes a set of head terms of the standard basis w.r.t. $\prec^{-1}$, on $\mathcal{A}$. By Lemma 25 (and Theorem 7, Proposition 8 and Theorem 9 of the paper Tajima and Nakamura 2009), for all $\bar{a} \in \mathcal{A}$, it is obvious that if $\xi^\lambda \in \text{FL}$ is not in $\text{LList}$, then the monomial $x^\lambda$ itself is in the ideal $\langle \sigma_{\bar{a}}(F) \rangle$ in $\bar{K}[[x]]$, and if $\xi^\lambda \in \text{FL}$ is in $\text{LList}$,

then $\sigma_{\bar{a}}\left(x^\lambda - \sum_{\xi^\kappa \in \text{ht}(\text{SList})} c_{(\kappa, \lambda)}x^\kappa\right)$ is also in $\langle \sigma_{\bar{a}}(F) \rangle$ and $\xi^\lambda$ is not in $\text{ht}(\text{SList})$ w.r.t. $\prec$. Hence, for all $\bar{a} \in \mathcal{A}$, $\sigma_{\bar{a}}(\text{SB}_{\text{SList}, \text{LList}}(\text{FL}))$ is the reduced standard basis of $\langle \sigma_{\bar{a}}(F) \rangle$ w.r.t. $\prec^{-1}$ on $\mathcal{A}$. \qed

This theorem leads us to construct the following algorithm for computing parametric standard bases.

Algorithm 14. (StandardBases1)

**Specification: StandardBases1($F$)**

Computing a parametric standard basis for a zero-dimensional ideal $\langle F \rangle$.

**Input:** $F \in (K[t])[x]$, $\prec$: a global total degree lexicographic term order.

**Output:** $(\mathcal{S}, \mathcal{A}_2)$: $\mathcal{S}$ is a set of pairs $(\mathcal{A}, E)$ such that for all $\bar{a} \in \mathcal{A}$, $\sigma_{\bar{a}}(E)$ is the reduced standard basis of $\langle \sigma_{\bar{a}}(F) \rangle$ w.r.t. $\prec^{-1}$. $\mathcal{A}_2$ is described in the algorithm $\text{ALCohomology}$. 26
In case (ii), each element of $FL$ is transformed as follows:

$$x \rightarrow \text{neighborhood of the origin} s,t$$

with parameters

- If the parameters belong to $V(t^2 - 4)$, $S\leftarrow S\cup\{(s, t)\}$, $SList = \{\xi^3, \xi^2, \xi, \xi^{-1}\}$, $SList = \{\xi^3, \xi^2, \xi, \xi^{-1}\}$ and $MList = \{\xi^3, \xi^2, \xi, \xi^{-1}\}$ and $FL = \{\xi^3, \xi^2, \xi, \xi^{-1}\}$.

Example 28. Let $f = x_1^4 + tx_1^3x_2 + x_1^4$ be a polynomial with a parameter $t$ in $(\mathbb{C}[t])[x_1, x_2]$ and $\prec$ be the global total degree lexicographic term order such that $\xi_1 \prec \xi_2$. Set $F = \{x_1, x_2\}$. The output of $\text{ALCohomology}(F)$, is already given in Example 16.

(i) On $V(t)$, $SList = \emptyset$, $MLList = \{1, \xi_1, \xi_2, \xi_3, \xi_4, \xi_5, \xi_6, \xi_7, \xi_8, \xi_9, \xi_{10}\}$, $MList = \emptyset$ and $FL = \{\xi_3, \xi_2\}$.

(ii) On $\mathbb{C}^2 \setminus V(t^2 - 4)$, $SList = \{\xi_1, \xi_2, \xi_3, \xi_4, \xi_5, \xi_6, \xi_7, \xi_8, \xi_9, \xi_{10}\}$, $MLList = \{1, \xi_1, \xi_2, \xi_3, \xi_4, \xi_5, \xi_6, \xi_7, \xi_8, \xi_9, \xi_{10}\}$ and $FL = \{\xi_1, \xi_2, \xi_3, \xi_4\}$.

In case (i), $SB_{\text{(SLList,MLList)}}(FL) = \{x_1, x_2\}$ is the reduced standard basis of $(F)$ w.r.t. $\prec$.

In case (ii), each element of $FL$ is transformed as follows:

$$\xi^3 \rightarrow x_1^3 + x_1^3x_2^2, \quad \xi_2^3 \rightarrow x_1^3x_2^2 + x_1^3x_2^2, \quad \xi_1^3 \rightarrow x_1^3x_2^3, \quad \xi_2^3 \rightarrow x_1^3x_2^3$$

Therefore, $\langle x_1^3 + \frac{1}{2}x_1x_2^3, x_1^3x_2^3 + \frac{1}{2}x_1^3x_2^3, x_1^3x_2^3 \rangle$ is the reduced standard basis of $(F)$ w.r.t. $\prec$.

Let us remark that if $t = \pm 2$, then $(F)$ is not zero-dimensional in $K[x]$.

All algorithms of this paper have been implemented in the computer algebra system Risa/Asir by the authors. In the following example, we give an output of our implementation.

Example 29. Let $F = \{3sx_1^2 + x_1^3 + tx_1^3x_2^2 + x_1^3 + 5x_1^3 + 3tx_1^3x_2^3\}$ be a set of polynomials with parameters $s, t$ in $(\mathbb{C}[s, t])[x_1, x_2]$, and $\prec$ be the global total degree lexicographic term order such that $x_1 \prec x_2$. Generically, $F$ has only the point $O$ in $X$ where $X$ is a neighborhood of the origin $O$ of $\mathbb{C}^2$. The variables $\xi_1, \xi_2$ are corresponding to variables $x_1, x_2$. Our implementation outputs bases of the vector space $H_F$ and standard bases of $(F)$ on $\mathbb{C}^2$ w.r.t. $\prec$.

- If the parameters belong to $V(s)$, then $(F)$ is not zero-dimensional.

- If the parameters belong to $V(s)^{\mathbb{C}} \setminus V(s(15s + 2t))$, then a set $\{1, \xi_1, \xi_2, \xi_3, \xi_4, \xi_5\}$ is a basis of $H_F$. Hence, $\langle s^2tx_1^3 + \frac{1}{2}t(15s + 2t)x_1^3x_2, s^2tx_1^3x_2^2, s^2tx_1^3x_2^3 \rangle$ is a parametric standard basis w.r.t. $\prec$.

- If the parameters belong to $V(15s + 2t) \setminus V(s)$, then a set $\{1, \xi_1, \xi_2, \xi_3\}$ is a basis of $H_F$. Hence, $\langle s^2tx_1^3x_2, s^2tx_1^3x_2^2, s^2tx_1^3x_2^3 \rangle$ is a parametric standard basis w.r.t. $\prec$.

- If the parameters belong to $V(t) \setminus V(s)$, then a set $\{1, \xi_1, \xi_2, \xi_3\}$ is a basis of $H_F$. Hence, $\langle s^2tx_1^3x_2, s^2tx_1^3x_2^2, s^2tx_1^3x_2^3 \rangle$ is a parametric standard basis w.r.t. $\prec$.
Note that in case $V(t) \setminus V(s,t)$, the dimension of the vector space $H_F$ is 8, but in cases $\mathbb{C}^2 \setminus V(st(-15s+2t))$ and $V(-15s+2t) \setminus V(s,t)$, the dimension of the vector spaces $H_F$ are 7. Our implementation tells us this deference.

4.2. Other local term orders

The algorithm AL Cohomology has been constructed based on a global total degree lexicographic term order $\prec_1$. That’s why reduced standard bases w.r.t. $\prec_1^{-1}$, are directly obtained by outputs of the algorithm AL Cohomology. Here, we describe how to compute standard base w.r.t. other local term orders.

Let $(S,D)$ be an output of AL Cohomology($F$) and $\prec$ be a global term order in $K[x]$. Suppose that $[A, SList, MList, LList, FL] \in S$, $SList = \{\psi_1, \ldots, \psi_p\} \subset K[x]$ and the list $\{\xi_1, \xi_2, \ldots, \xi_r\}$ is lined up all elements of Mono($SList$) in order of $\prec$ where $\xi_r \prec \xi_{r-1} \cdots \prec \xi_1$. Moreover, let $M$ the coefficient matrix of $SList$ w.r.t. the vector $\{\xi_1, \xi_2, \ldots, \xi_r\}$ (i.e., $\bar{M} = M^{\xi_1, \xi_2, \ldots, \xi_r}$) where $\bar{M} = \bar{M}^{\xi_1, \xi_2, \ldots, \xi_r}$.) Then, it is possible to compute the row reduced echelon matrix of $M$ on $A$, like a method for solving the system of parametric linear equations. Let $\{(A_1, M'_1), (A_2, M'_2), \ldots, (A_l, M'_l)\}$ be a set of pairs such that for each $1 \leq i \leq l$, $M'_i$ is the row reduced echelon matrix of $M$ on $A_i$ and $A = A_1 \cup \cdots \cup A_l$. Then, we have the following theorem.

Theorem 30. Using the same notation as in above discussion, let $\bar{M}^{\xi_1, \xi_2, \ldots, \xi_r} = M'_i = M'_{\xi_1, \xi_2, \ldots, \xi_r}$ where $1 \leq i \leq l$. Suppose that $\pi L = \{\psi_1, \psi_2, \ldots, \psi_p\}$, $L = Mono(SList) \setminus ht(SL), T = ht(SL) \cup MList$ and the reduced Gröbner basis of $\langle \text{Neighbor}(T) \setminus T \rangle$ is FL$\prec$ w.r.t. $\prec$. Then, for all $\bar{a} \in \bar{A}$, $\sigma_\bar{a}(SB_{(SL, L)}(FL_\prec))$ is the reduced standard basis of $\langle \sigma_\bar{a}(F) \rangle$ w.r.t. $\prec^{-1}$ in $K[[x]]$. (The transfer $SB_{(SL, L)}$ is from Notation 26.)

Proof. As $SList \cup MList$ is a basis of $H_F$ on $A$, it is obvious that $SList \cup MList$ is a basis of $H_F$ on $A_i$, too. $L$ is a set of lower terms of $SList$ w.r.t. $\prec$. Since $M'_i$ is the row reduced echelon matrix of $M$ w.r.t. the vector $\bar{M}^{\xi_1, \xi_2, \ldots, \xi_r}$ on $A_i$, the set $\mathcal{C}V^{-1}(FL_\prec)$ becomes a set of head terms of the standard basis w.r.t. $\prec^{-1}$ on $A_i$. By this observation and Theorem 27, this theorem holds. $\Box$

This theorem leads us to construct the following algorithm for computing parametric standard bases w.r.t. any local term order.

Algorithm 15. (StandardBases2)

**Specification:** StandardBases2($F, \prec$)

Computing a parametric standard basis for $\langle F \rangle$ w.r.t. $\prec$.

**Input:** $F \subset (K[t])[x], \prec$: a local term order.

**Output:** $(S, A_2)$: $S$ is a set of pairs $(A, E)$ such that for all $\bar{a} \in \bar{A}$, $\sigma_\bar{a}(E)$ is the reduced standard basis of $\langle \sigma_\bar{a}(F) \rangle$ w.r.t. $\prec$. $A_2$ is described in the algorithm AL Cohomology.

**BEGIN**

$S \leftarrow \emptyset; (A_1, A_2) \leftarrow$ AL Cohomology($F$)

**while** $A_1 \neq \emptyset$ **do**

**select** $B = [A, SList, MList, LList, FA] \text{ from } A_1; A_1 \leftarrow A_1 \setminus \{B\}$

$v \leftarrow \text{Line up all elements of Mono}(SList) \text{ w.r.t. } \prec^{-1}$.

**END**
$M \leftarrow $ Make the coefficient matrix of SLList w.r.t. $v$
$\mathcal{A}M \leftarrow $ Compute the row reduced echelon matrix of $M$ on $\mathbb{A}'$
while $\mathcal{A}M \neq \emptyset$
do
select $(\mathbb{A}'',M')$ from $\mathcal{A}M$; $\mathcal{A}M \leftarrow \mathcal{A}M\setminus\{(\mathbb{A}'',M')\}$
(where $M'$ is the row reduced echelon matrix of $M$ on $\mathbb{A}'$.)
$t(\varphi_1,\varphi_2,\cdots,\varphi_\rho) \leftarrow M'\ tv$; $SL \leftarrow \{\varphi_1,\varphi_2,\cdots,\varphi_\rho\}$
$L \leftarrow \text{Mono}(SL)\setminus \text{ht}(SL)$; $T \leftarrow \text{ht}(SL)\cup\text{MList}$
$\text{FL}_\prec \leftarrow$ the reduced Gröbner basis of $\langle \text{Neighbor} (T)\setminus T \rangle$
$S \leftarrow S\cup\{(\mathbb{A}'',SB_{(SL,L)}(\text{FL}_\prec))\}$
end-while
end-while
\return $(S,A_2)$
\END

\textbf{Example 31.} Let $f = x_1^4+tx_2^2x_3^2+x_3^4$ be a polynomial with a parameter $t$ in $(\mathbb{C}[t])[x_1,x_2]$. Set $F = \left\{ \frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2} \right\}$. The output of \texttt{ALCohomology}(F), is already given in Example 16.

If a parameter $t$ belongs to $\mathbb{C}\setminus V(t(t^2-4))$, then $\{1,\xi_1,\xi_2,\xi_3,\xi_1\xi_2,\xi_1\xi_3,\xi_2\xi_3,\xi_1\xi_2\xi_3\}$ is a basis of $H_F$. Let $\prec$ be the local lexicographic term order such that $x_1 \prec x_2$ and $SL = \{\xi_1\xi_2^2,\xi_1^2\xi_3,\xi_1^2\xi_2,\xi_1^2-\xi_1^2\xi_2\xi_3,\xi_1^2\xi_2^2\xi_3\}$. We compute a parametric standard basis of $\langle F \rangle$ w.r.t. $\prec$ on $\mathbb{C}\setminus V(t(t^2-4))$. First, we line up all elements of Mono(SLList) w.r.t. $\prec^{-1}$ (the global lexicographic term order), then we get the vector $v = t(\xi_1,\xi_1^2,\xi_1^2\xi_2,\xi_1^2\xi_3,\xi_1^2\xi_2\xi_3)$. The coefficient matrix of SLList w.r.t. $v$ is $M$, and the row reduced echelon matrix of $M$ is $M'$:

\[
M = \begin{pmatrix}
\xi_1^4 & \xi_1^3 & \xi_1^2\xi_2 & \xi_1^2\xi_3 & \xi_1\xi_2^2 & \xi_1\xi_2\xi_3 & \xi_1^2 \xi_2^2 \\
0 & -1/2t & 0 & 0 & 1 & 0 \\
0 & 0 & -1/2t & 0 & 0 & 1 \\
1 & 0 & -1/t & 0 & 0 & 1
\end{pmatrix}, \quad M' = \begin{pmatrix}
1 & 0 & -1/t & 0 & 0 & 1 & 0 \\
0 & 1 & 0 & -2t & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & -2t
\end{pmatrix}.
\]

Then, $M'\ tv = t(\xi_1^4-\xi_1^3\xi_2^2,\xi_1^3-2t\xi_1^2\xi_3,\xi_1^2\xi_2^2-2t\xi_1^2\xi_2).$ Hence, $SL = \{\xi_1^4-\xi_1^3\xi_2^2,\xi_1^3-2t\xi_1^2\xi_3,\xi_1^2\xi_2^2-2t\xi_1^2\xi_2\},$ $\text{ht}(SL) = \{\xi_1^4,\xi_1^3\xi_2,\xi_1^2\xi_3\},$ $L = \text{Mono}(SL)\setminus \text{ht}(SL) = \{\xi_1^3\xi_2,\xi_1^2\xi_3,\xi_1^2\xi_2^2\}$ and $T = \text{ht}(SL)\cup\text{MList}$. Since the set $\text{FL}_\prec = \{\xi_1^3\xi_2,\xi_1^2\xi_3,\xi_1^2\xi_2^2\}$ is the reduced Gröbner basis of $\langle \text{Neighbor} (T)\setminus T \rangle$, the parametric standard basis of $\langle F \rangle$ w.r.t. $\prec$ on $\mathbb{C}\setminus V(t(t^2-4))$ is $SB_{(SL,L)}(\text{FL}_\prec) = \{x_1^5,\xi_1^3\xi_2,\xi_1^2\xi_3,\xi_1^2\xi_2^2\xi_3\}.$

In Fig. 7, we represent an element of MList as $\bullet$, an element of $\text{ht}(SL)$ as $\triangle$. As the set $\text{FL}_\prec$ plays a key role to construct standard bases, we give the elements of $\text{FL}_\prec$ in the figure.

\caption{Fig. 7}
\end{figure}
5. Conclusions

We have described algorithms for computing parametric local cohomology systems, and given a new algorithm for computing parametric standard bases as an application. The algorithm for computing parametric standard bases, has the following advantages.

- The algorithm always outputs a “reduced” standard basis. The computer algebra system Singular has a command that outputs a (non-parametric) standard basis. Singular does not have this property.
- The substantial computation consists of only linear algebra computation.
- We do not need Mora’s reduction (tangent cone algorithm (Mora, 1982)) for computing standard bases.
- The algorithm outputs a nice decomposition of the parameter space depending on the structure of standard bases w.r.t. a local total degree lexicographic term order.

All algorithms of this paper, have been implemented in the computer algebra system Risa/Asir. Actually, there does not exist any implementation for computing “parametric” standard bases, except for our implementation. Only our implementation exists for them. Our implementation is useful for studying and analyzing singularities.
