Abstract

Background: Choline is an indispensable vitamin of fish; which deficiency affects fish health. Fish health is affected by skin immune function. Hence, the present study was conducted to investigate the effects of dietary choline on skin immune function as well as underlying mechanisms of juvenile grass carp (*Ctenopharyngodon idella*).

Results: The results exhibited that dietary choline (1) advanced the content of phosphatidylcholine (PC), betaine, and choline in grass carp skin (*P* < 0.05), up-regulated the mRNA abundance of choline transporter CHT1, CTL5, and CTL1 indicating that dietary choline could increase the contents of choline might be connected with choline transporters in the grass carp skin; (2) receded skin lesion and increased the level of IgM, C4, C3, and the activities of acid phosphatase (ACP) and lysozyme activity (LZ), raised mucin2, β-defensin, hepcidin, and LEAP-2B mRNA abundance (rather than LEAP-2A), down-regulated pro-inflammatory cytokines mRNA abundance (IFN-γ, IL-15, TNF-α, IL-6, IL-12P40, and IL-1β) in skin of juvenile grass carp (*P* < 0.05), up-regulated anti-inflammatory cytokines mRNA abundance (IL-10, IL-4/13A, TGF-β1, IL-11, and IL-4/13B) in grass carp skin (*P* < 0.05) demonstrating that choline enhanced the skin immune function; (3) down-regulated the mRNA abundance of IKKγ, NF-κBp52, c-Rel, NF-κBp65, STAT3b2, STAT3b1, JAK1, and JAK2 as well as protein level of NF-κBp65 and p-STAT3 Tyr705 in nucleus, inhibited the mRNA and protein level of IkBα (*P* < 0.05), indicating that choline enhanced immune function might be relevant to JAK/STAT3 and NF-κB signaling pathway in fish skin.

Conclusions: In conclusion, choline enhanced the skin immune function might be relate to JAK/STAT3 and NF-κB signaling molecules in fish. Furthermore, based on immune indices of grass carp (9.28-108.97g) skin (C3 and IgM contents as well as ACP activities), the choline requirements were estimated to be 1475.81, 1364.24, and 1574.37 mg/kg diet, respectively.

1. Introduction

Intensive aquaculture increases diseases infection risk of fish[16]. Improving immunity is crucial for the prevention and control of diseases in fish[2]. Skin is a crucial immune organ in fish[3], whose health is important for fish growth and diseases resistance[4]. Fish skin immune function is tightly correlated with specific immune factors like immunoglobulins and nonspecific immune factors like LZ [5]. Furthermore, fish skin immunity is closely related to the cytokines. Murray (2008) found that anti-inflammatory cytokines could be regulated by STAT3 as well as upstream signaling molecule Janus kinases (JAK) in humans [6], while pro-inflammatory cytokines expression could be mediated by NF-κB[7]. Vitamin B like biotin (VB7) could enhance the immune function of grass carp skin[8]. However, as a vitamin B, no researches regarding the effect of choline on fish skin immunologic function and potential mechanisms. Choline enters the cell via choline transporters and produce corresponding metabolite to play biological functions[9]. Betaine as one of vital metabolite, which could decrease the content of tumor necrosis factor-α (TNF-α) in rat liver[10, 11]. In mouse brain, choline enhanced the acetylcholine (ACh) level which could activate JAK2/STAT3 signaling pathway in mouse PC12 cells[12, 13]. In human, choline synthesis PC which restrained NF-κBp65 protein level in rat IEC-6 cells[14, 15]. Thus, there might be a relationship between immune function and choline, which may be related to JAK/STAT3 and NF-κB signaling pathway in fish skin. This research is of great value.

Most researches of vitamins concentrated on liver health and nutritional requirements [16, 17]. So far, scattered reports regarding the impacts of vitamin on fish skin immunity. And there still remain following restrictions: 1) in limited researches, we found that those researches are not deeply and systematically enough. Most studies mainly focused on the antibiotic substance contents and the inflammatory factors gene expression, did not investigate the involved mechanisms[8, 18]. 2) the in-depth mechanisms of various vitamin on fish skin immune function are contrasting. Such as, dietary VB7 supplement enhanced skin immune function might be connected with key enzymes activity such as
In current study, the growth trial was selfsame to our prior study. The study determines the dietary choline enhanced fish growth performances [19] which were influenced by the skin immune function[20]. Grass carp are the world’s most farmed fish [21]. Hence, we explored the influences of choline on fish skin immune function, which partially declared the impact of choline on skin immune function and underlying mechanisms in fish. Simultaneously, vitamin requirements based on fish production performance are lower than the immune function of juvenile grass carp [18, 22], so we determined the optimum choline requirements depend on the immune indicator for juvenile grass carp, which may provide basis for production practice.

2. Material And Methods

2.1. Experiments and feeding management

The current study used the selfsame animal trial as our prior research [19]. The feed formula showed in Table 1, which was commensurate with prior research. Fishes were fed with 6 various gradient choline dietary for 70 days. The choline levels were 142.2 (0), 407.4 (400), 821.6 (800), 1215.8 (1200), 1589.3 (1600) and 1996.6 (2000) mg kg\(^{-1}\) in 6 diets, respectively (The value in front of the brackets is the measured value, and the value in the brackets is the design value). The actual choline level was determined by the way from Ding and Mou [23],
Table 1  
Composition and nutrients of basal diet.

| Ingredients                                         | %     | nutrients   | %     |
|-----------------------------------------------------|-------|-------------|-------|
| Fish meal                                           | 3.97  | Crude protein$^d$ | 31.92 |
| Casein                                              | 28.27 | Crude lipid$^d$  | 4.22  |
| Gelatin                                             | 7.00  | n-3 Fatty$^e$  | 1.04  |
| α-starch                                            | 24.00 | n-6 Fatty$^e$  | 0.96  |
| Corn starch                                         | 18.72 | Available phosphorus | 0.84  |
| Fish oil                                            | 2.63  |              |       |
| Soybean oil                                         | 1.80  |              |       |
| Microcrystalline cellulose                          | 5.00  |              |       |
| Ca(H$_2$PO$_4$)$_2$                                  | 3.30  |              |       |
| Choline-free vitamin premix $^a$                    | 1.00  |              |       |
| Mineral premix $^b$                                  | 2.00  |              |       |
| Choline chloride premix $^c$                         | 2.00  |              |       |
| DL-Met(99%)                                         | 0.26  |              |       |
| Ethoxyquin (30%)                                     | 0.05  |              |       |

$^a$ Per kilogram of choline-free vitamin premix (g kg$^{-1}$): retinyl acetate (1000,000 IU g$^{-1}$), 0.400; cholecalciferol (500,000 IU g$^{-1}$), 0.320; DL-a-tocopherol acetate (50%), 40.000; menadione (96%), 0.198; cyanocobalamin (1%), 0.940; D-biotin (2%), 0.750; folic acid (95%), 0.379; thiamine nitrate (98%), 0.133; ascoryl acetate (95%), 4.737; niacin (99%), 2.576; meso-inositol (97%), 22.062; calcium-D-pantothenate (90%), 2.778; riboflavin (80%), 0.775; pyridoxine hydrochloride (98%), 0.011. All ingredients were diluted with corn starch to 1 kg.

$^b$ Per kilogram of mineral premix (g kg$^{-1}$): MnSO$_4$.H$_2$O (31.8% Mn), 3.098; MgSO$_4$.H$_2$O (15.0% Mg), 237.840; FeSO$_4$.H$_2$O (30.0% Fe), 15.000; ZnSO$_4$.H$_2$O (34.5% Zn), 7.860; CuSO$_4$.5H$_2$O (25.0% Cu), 0.600; CaI$_2$ (3.2% I), 1.560; Na$_2$SeO$_3$ (44.7% Se), 0.132. All ingredients were diluted with corn starch to 1 kg.

$^c$ Per kilogram of choline chloride premix (g/kg): premix was added to obtain graded level of choline. Each choline chloride mixture was diluted with corn starch to 1 kg referenced to Wu et al. (2010)

$^d$ Crude protein and crude lipid contents were measured values.

$^e$ n-3 and n-6 were calculated by NRC (2011) contents were referenced to Zeng et al. (2016).

$^f$ Available phosphorus were calculated according to NRC (2011).

All experimental procedures were approved by Animal Protection Advisory Committee of Sichuan Agricultural University [24]. Fishes were purchased from the fishery (Chengdu, China). Before the experiment, 4-weeks feeding was to adapt to the environment. After that 1440 fishes with average weight of 9.29 g were randomly assigned to 36 aquariums (0.144 m$^3$). The same continuous aeration and recirculating water was maintained to each aquarium [25]. During
growth experiment, the dissolved oxygen level ranged from 6.2 mg/L to 7.0 mg/L, pH was measured at 7.0 ± 0.3 and water temperature at 28 ± 2 °C. Fishes were fed 4 times every day[24, 26].

2.2. Challenge test

The bacteria were supplied by college of Veterinary Medicine, Sichuan Agricultural University. Prior to initiation of the challenge test, based on skin lesion morbidity, we determined appropriate challenge concentration after injection graded levels of *A. hydrophila* in fish. After 70 days of feeding, 42 fishes with similar body weight were intraperitoneal challenge injection with $2.1 \times 10^6$ CFU/ml *A. hydrophila*. After injection for 6 days[27], put the skin of each group into liquid nitrogen, and reserved in -80 °C.

2.3. Measurement of choline metabolite contents and immune parameters activities

10% fish tissue homogenate was prepared to detected the caspase activities and choline metabolite level as described [1]. Using commercial assay kits (Nanjing Jiancheng Bioengineering Institute) to detected the IgM, C4, C3 ACP and LZ levels according to Takemura et al. (1993), Huang et al. [28, 29].The level of ACh, betaine, PC, and choline were determined by ELISA kits (Shanghai Kexing Trading Co., Ltd, China). The level of ACh, betaine, PC, and choline were calculated on the basis of standard curves.

2.4. Quantitative real-time PCR

The skin total RNA was extract using RNAiso Plus kit (TaKaRa Bio Inc., Japan) following the specification. Thenceforth, referring the instruction to synthase cDNA by PrimeScript™ RT reagent Kit (TaKaRa). The qRT-PCR primers were referred to the published sequences of grass carp in our lab prior study, which were shown in Table 2. The gene amplification efficiency was measured by melting curve. Using $2^{-\Delta\Delta CT}$ method to calculate the gene expression as described by Hu et al [30].

### 2.5. Western blotting

Using lysis buffer and protease inhibitor cocktail to prepare skin homogenate[7]. The protein level was determined by BCA assay kit (Beyotime Biotechnology Inc.). β-action, laminB1, p-STAT3Tyr705, NF-κBp65, and IkBα antibodies are same to our early research [27, 31]. LaminB1 and β-Actin were used as control proteins for nuclei and cells total protein, respectively. protein samples were separated by DS-PAGE and shift to PVDF membrane. Using 5% BSA to blocked PVDF membrane. After incubation the antibodies, using electrochemiluminescence (ECL) Kit to exposure. Finally, using Image Lab 5.1 software analyse western bands.

### 2.6. Statistical analysis

Using Shapiro–Wilk and Levene's tests to test the homogeneity and normal distribution of variance by SAS 8.1 (SAS Institute), respectively. Using one-way variance (ANOVA) to analysis data[32]. The significant differences between every treatment means were contrasted by Duncan's multiple range tests (significant difference at the 5% level of significance, $P<0.05$[33]). The choline requirement and correlations were estimated by broken-line mode and Pearson's correlation, respectively [24].

### 3. Results

#### 3.1. The contents of choline and its metabolites and the gene expression of choline transporter

As shown in Table 3, the level of PC, betaine, and choline were raised with dietary choline up to 1589.3, 1589.3, and 1215.8 mg/kg ($P<0.05$), and then plain, respectively. However, the content of ACh did not change with the increase of choline content ($P>0.05$). Choline transporter mRNA abundance of skin were exhibited in Fig. 2, CTL2 and CTL5 mRNA abundance were raised with dietary choline add to 1215.8, and 1589.3 mg/kg ($P<0.05$), respectively, then flat. HCT1 mRNA abundance was slowly increased with dietary choline addition ($P<0.05$). Dietary choline did not change the mRNA abundance of CTL1 and CTL4 in fish skin ($P>0.05$).

¹ Values are means ± SD (n = 6), and different superscripts in the same row are significantly different (P < 0.05).

3.2. Skin rot morbidity and activities of immune parameters in grass carp skin.

Choline insufficiency caused skin rot symptom, as shown in Fig. 1. As exhibited in Table 4, the activities of ACP and LZ in grass carp skin was ascend as dietary choline level increased to 1215.8 g/kg (P < 0.05), then plateaued. The level of C3, IgM, and C4 in the skin was ascend as dietary choline supplements to 1589.3, 821.6, and 1215.8 g/kg (P < 0.05), respectively, then all plateaued. The antibacterial peptides mRNA abundance of skin was presented in Table 3A, mucin2, and LEAP-2B mRNA abundance was raised with dietary choline level add to 1215.8, and 821.6 mg/kg (P < 0.05), respectively, then flat. The mRNA levels of hepcidin, and β-defensin-1 was raised with choline supplements to 1589.3 mg/kg (P < 0.05), then decreased. Nevertheless, mRNA abundance of LEAP-2A did not influence by choline (P > 0.05). As exhibition in Fig. 3B, the mRNA abundance of TNF-α, IL-15, IL-6, IL-12p40, and IL-1β in skin of juvenile grass carp were descend with dietary choline level increased to 821.6, 1215.8, 1589.3, 1215.8, and 1215.8 mg/kg, respectively (P < 0.05), and then flat. The mRNA abundance of IFN-γ2 in skin of juvenile grass carp were descend with dietary choline addition (P < 0.05). In Fig. 3C, the mRNA abundance of anti-inflammatory cytokine IL-4/13B, IL-10, IL-11, and IL-4/13A in skin of fish (P < 0.05) were elevated with choline level increased to 1589.3, 1215.8, 1589.3, and 1589.3 mg/kg, respectively (P < 0.05). TGF-β1 mRNA abundance in fish skin was elevated with dietary choline addition (P < 0.05). Remarkably, the mRNA abundance of IL-17D, TGF-β2, IL-12p35 did not impact by dietary choline (P > 0.05).
Table 4

Effects of dietary choline (mg/kg diet) on immune parameters in juvenile grass carp (Ctenopharyngodon idella) skin.1

| Dietary choline levels (mg/kg diet) | 142.2  | 407.4  | 821.6  | 1215.8 | 1589.3 | 1996.6 |
|-------------------------------------|--------|--------|--------|--------|--------|--------|
| C3                                 |        |        |        |        |        |        |
| 11.08 ± 1.00^a                      | 15.25 ± 1.29^b | 16.62 ± 1.63^b | 19.24 ± 0.91^c | 20.97 ± 1.06^d | 20.33 ± 1.75^cd |
| C4                                 |        |        |        |        |        |        |
| 1.20 ± 0.12^a                       | 1.98 ± 0.14^b | 3.07 ± 0.24^c | 4.07 ± 0.30^d | 3.51 ± 0.32^d | 3.40 ± 0.31^d |
| IgM                                |        |        |        |        |        |        |
| 31.60 ± 3.05^a                      | 30.53 ± 2.97^a | 40.94 ± 3.95^b | 42.02 ± 2.53^b | 43.13 ± 2.38^b | 41.79 ± 4.18^b |
| ACP                                |        |        |        |        |        |        |
| 66.83 ± 7.15^a                      | 87.72 ± 8.36^b | 88.47 ± 7.70^b | 101.58 ± 11.17^c | 117.07 ± 7.53^c | 111.39 ± 9.66^c |
| LZ                                 |        |        |        |        |        |        |
| 81.01 ± 8.34^a                      | 107.51 ± 9.83^b | 114.73 ± 10.49^b | 136.99 ± 14.68^b | 139.07 ± 15.07^c | 128.97 ± 6.95^c |

1 Values are means ± SD (n = 6), and different superscripts in the same row are significantly different (P < 0.05). Lysozyme activity (U/mg protein); ACP, acid phosphatase (U/mg protein); C3, complement 3 (mg/g protein); C4, complement 4 (mg/g protein); IgM, immunoglobulin M (mg/g protein).

3.3. JAK/STAT3 signaling pathways and NK-κB signaling pathways mRNA abundance in fish skin

As exhibition in Fig. 4, in juvenile grass carp skin, the mRNA abundance of IKK-γ, NF-κB p65, c-Rel, NF-κB p52, and IKK-β were descend with dietary choline level to 1589.3, 1215.8, 1215.8, 1589.3, and 1589.3 mg/kg, respectively (P < 0.05), and then plateaued. IκBα mRNA levels was increased with dietary choline level up to 1589.3 (P < 0.05), and then flat. In Fig. 5, the mRNA abundance of JAK1, JAK2, STAT3b1, and STAT3b2 were elevated with choline add to 1215.8, 1589.3, 1589.3, and 1589.3 mg/kg, respectively (P < 0.05), and then plateaued. Tyk2 mRNA levels was highest in 407.4 mg/kg choline diet (P < 0.05). However, dietary choline had no influence on mRNA abundance of IKKα, JAK3, and STAT3a in skin of juvenile grass carp. As shown in Fig. 6, NF-κB p65 protein level in the nucleus was descend with choline supplements to 1215.8 mg/kg (P < 0.05) then plateaued. The IκBα protein level and p-STAT3 Tyr705 protein level in the nucleus were elevated with dietary choline addition to 1589.5 mg/kg, respectively (P < 0.05).

4. Discussion

This research used a growth experiment selfsame to our earlier study [19], which found choline improved fish growth performances of juvenile grass carp[19]. Furthermore, fish growth performances were deeply related to the immune function of immune organs[27], Hence, we explored how choline impact the skin immune function of fish in this study.

4.1. Dietary choline increased the content of choline and its metabolites and up-regulated the gene expression of choline transporter in skin

Dietary choline was absorbed by guts and through blood travels to different tissues where it can be oxidized, phosphorylated, acetylated and produce corresponding metabolite, such as betaine, PC, and ACh. In our research, dietary choline could increase the content of betaine, PC, and choline in fish skin. Results commend that the optimal choline increased choline content and corresponding metabolite in fish skin. In mammal enterocytes, choline can be transported though transport systems [9]. Such as, choline transporter-like proteins (CTLs) and high-affinity choline transporters (CHT1) [9]. In this research, we found that optimal dietary choline up-regular the mRNA level of CTL2, CTL5, and HCT1, which indicated that skin absorbed choline through choline transporter CTL2, CTL5, and HCT1. Base on choline content and choline transporters mRNA abundance, the positive correlation was found in Table 5, we
conjectured that the up-regular of those choline transporters mRNA abundance might be related to the increase of choline contents in fish skin.
Table 5
Correlation analysis of parameters in the skin of juvenile grass carp (*Ctenopharyngodon idella*)

| Independent parameters | Dependent parameters | Correlation coefficients | P    |
|------------------------|----------------------|--------------------------|------|
| choline                | CTL2                 | 0.981                    | < 0.01 |
|                        | CTL5                 | 0.959                    | < 0.01 |

### Table 1: Correlation coefficients between independent and dependent parameters

| Independent parameters | Dependent parameters | Correlation Coefficients | P  |
|------------------------|----------------------|---------------------------|----|
| IL-4/13B               |                      | 0.981                     | < 0.01 |
| STAT3b2                | TGF-β1               | 0.829                     | 0.042 |
| IL-10                  |                      | 0.95                      | < 0.01 |
| IL-11                  |                      | 0.879                     | 0.021 |
| IL-4/13A               |                      | 0.96                      | < 0.01 |
| JAK1                   | STAT3b1              | 0.937                     | < 0.01 |
| JAK1                   | STAT3b2              | 0.966                     | < 0.01 |
| JAK2                   | STAT3b1              | 0.92                      | < 0.01 |
| JAK2                   | STAT3b2              | 0.968                     | < 0.01 |

Striking, choline has no impact on the fish skin CTL4 mRNA abundant, which might be associated with ACh. CTL4 involved in the synthesis ACh in animals [34]. However, in our research, choline did not influence the ACh content of grass carp skin, which provides an important basis for our hypothesis.

### 4.2. Dietary choline reduced skin lesion morbidity and enhanced immune function in the fish skin

*A. hydrophila* is a potentially pathogenic bacteria that can cause fish skin lesion and even lead to death. [33]. Hence, after growth trail using *A. hydrophila* trail to study the skin lesion degree. Challenge with *A. hydrophila*, we found that dietary choline deficiency lead to the peak skin lesion morbidity (28.17%), whereas sufficient choline abundance decreased skin lesion morbidity (8.45%) in grass carp. Furthermore, the skin lesion resistance partially relies on skin immune response in fish [34]. These results declared that sufficient dietary choline reduced skin lesion morbidity. In fish, the immune function was mainly influenced by antimicrobial peptides such as LEAP-2 and hepcidin and humoral components like C4 and IgM [35]. The above results indicated that optimal dietary choline enhanced the ACP and LZ activities, C3, IgM, and C4 contents and increased mucin2, β-defensin LEAP-2B, and hepcidin mRNA abundance in the fish skin. These results investigated that choline addition heightened the immune function in fish. The concentration of C4 in the optimal choline supplementation group was 3.39- fold that of the 142.2 mg/kg choline group, which was significantly higher than other enzyme activities and C3 content (1.36- to 1.89- fold). This indicates that the regulation of C4 by choline is more active and effective.

Interesting, considering the differences between the vitamins mentioned in the introduction, we compared choline with VB7 and α-lipoic acid[8, 36]. Unlike two other vitamins, choline deficiency did not affect LEAP-2A mRNA level, which might be partly relevant to IKKα. IKKα improved IL-22 level in mice[37], which enhanced LEAP-2A mRNA abundance in rainbow trout splenocytes[38]. However, in this research, choline supplementation did not affect IKKα mRNA abundance in fish skin, which might support our hypothesis. Moreover, these data also illustrated that LEAP-2A might be higher conscious by VB7, and α-lipoic acid in fish skin than dietary choline.

### 4.3. Dietary choline enhanced immune function referring to the mRNA abundance of inflammatory factors in the fish skin
Inflammation is a host defense mechanism, but overregulation of the inflammatory response disrupts the balance of immune function, leading to the deterioration of human diseases [37]. Morimoto et al. observed that the inflammatory function of fish immune organs was affected by inflammatory cytokines [39]. However, no research has studied the impacts of choline addition on inflammatory response in fish skin. In this research, we were the first time investigated that choline addition decreased the mRNA level of proinflammatory cytokines IFN-γ2, TNF-α, IL-15, IL-12p40, IL-6, and IL-1β and up-regulated the mRNA abundance of anti-inflammatory cytokines TGF-β1, IL-11, IL-10, and IL-4/13A in the grass carp skin. In short, all of the above results illustrated that dietary choline supplement improved the immune function in fish skin.

Interesting, the potential reasons for differential result are discussed as follows. First, our previous research found that appropriate dietary VB7 could descend the mRNA abundance of IL-12p35 (rather than IL-12p40)[8]. While, in our study, appropriate choline increased of fish skin IL-12p40 (not IL-12p35) mRNA abundance. This result might be related to TNF-α. In this research, appropriate dietary choline downregulated TNF-α mRNA levels in grass carp skin. In Atlantic salmon HK cells, TNF-α could increase the IL-12p40 (not IL-12p35) gene level [40], which supports our speculation. Moreover, these data also indicated that choline and VB7 had different regulatory mechanism between different subtypes of the same gene (such as IL-12p35 and IL-12p40). Second, dietary α-lipoic acid and VB7 decreased the mRNA abundant of IL-17D, but dietary choline did not influence the IL-17D mRNA abundant in fish skin was might be relevant to tryptophan. Tryptophan catabolites could inhibit the production of IL-17 in mice[41]. Previous studies have found that choline did not affect the content of tryptophan in the intestine[19], which might support our hypothesis and needs further investigation. In addition, these data also indicated that IL-17D is more easily regulated by dietary choline rather than α-lipoic acid and VB7 in fish skin. Third, choline insufficient did not influence the TGF-β2 mRNA abundant in fish skin, which might be partly related to methionine. Methionine regeneration was mediated by choline in bovine neonatal hepatocytes [42]. Methionine dipeptide supplementation has no impact on the TGF-β2 mRNA abundance of grass carp intestine[43], which needs further study. Moreover, previous studies found that dietary α-lipoic acid could up-regulate the mRNA abundant of TGF-β2, indicated that TGF-β2 is more easily regulated by dietary α-lipoic acid rather than choline in fish skin.

4.4. Dietary choline enhanced immune function referring to JAK/STAT3 and NF-κB signaling molecules in the fish skin

A previous study had found that inflammatory response is related to the mRNA expression of proinflammatory cytokines in fish[44]. Proinflammatory cytokines were regulated by the transcription factor NF-κB, like NF-κB p65 and p52 were inhibited by IκBα in mammalian cells[45]. Our data showed that the proinflammatory cytokines (IFN-γ2, IL1β, IL-6, TNF-α, IL-12p40, and IL-15) mRNA abundance was down-regulated by optimal dietary choline in grass carp skin, implying that optimal dietary choline enhanced inflammatory function in fish skin. Furthermore, optimal dietary choline restrained the NF-κB signaling pathway by activated the IκBα protein level and decrease nuclear NFκBp65 protein level, as well as c-Rel, IKKβ, NF-κBp65, IKKy, and NF-κBp52 (not IκBa) mRNA abundance in grass carp skin. C-Rel, NF-κB p52, and NF-κBp65 mRNA abundance was positively correlated with the pro-inflammatory cytokines mRNA abundance which showed in Table 5. As the same time, c-Rel, NF-κB p52, and NF-κB p65 mRNA abundance was positively related with IKKβ and IKKy mRNA abundance, which were inverse correlation with the IκBα mRNA abundance. These data elucidated that the optimal dietary choline down-regulated the proinflammatory cytokines mRNA abundance might be relevant to IKKβ and IKKy/IκBα/NF-κB signaling in the fish skin.

STAT3 signaling pathway plays an important role in promoting the gene expressions of anti-inflammatory cytokines in humans[6]. STAT3 is also a member of the STAT family, which can be activated by the upstream signaling molecule Janus kinases (e.g., JAK2)[46]. In this research, we were the first time investigated that choline addition increased the mRNA abundance of STAT3b1, STAT3b2, JAK1, and JAK2, as well as p-STAT3 Tyr705 protein level in fish skin (Fig. 5), which implying that dietary choline up-regulated most of anti-inflammatory cytokines might be partly related to STAT3.
signaling pathway. Correlation analyses (Table 5) showed that anti-inflammatory cytokines (IL-10, TGF-β1, IL-4/13A, IL-11, and IL-4/13B) were positively correlated with the STAT3b1 and STAT3b2 mRNA abundance in fish skin. Our data showed that weaken effect of the anti-inflammatory by dietary choline might be relevant to JAK1, JAK2/STAT3 signaling in grass carp skin.

Interestingly, choline has no impact on IKKα mRNA abundant of grass carp skin, which may be relevant to IFN-γ. This research indicated that dietary choline deficiency increased fish skin IFN-γ mRNA abundance. In U937 cells, IFN-γ enhanced protein kinase Cζ level[47], which increased IKKβ and IKKγ (not IKKα) gene abundance in Kupffer cells [48]. Further research is needed to confirm this hypothesis. Similar phenomena were discovered in VB7, and α-lipoic acid from our previous research in grass carp skin, which may illustrate that vitamins B is not sensitivity enough to IKKα in skin. Moreover, in human myeloid cells, macrophage colony stimulating factor (GM-CSF) could activate STAT3b (rather than STAT3a)[49]. However, choline supplementation had no effect on GM-CSF concentrations in rat placenta[50]. Therefore, we speculated that choline deficiency down-regulated STAT3b1/b2 rather than STAT3a gene expressions in fish skin may be caused by the decrease of GM-CSF. Further research is needed to confirm this hypothesis.

4.5. Choline requirements based on immune indices

Appropriate choline group advanced most of inflammatory indicators and receded skin lesion. Further, based on the skin immune indices (C3 and IgM contents as well as ACP activities) the choline requirements for grass carp (9.28-108.97 g) were estimated to be 1475.81, 1364.24, and 1574.37 mg/kg diet, respectively. The requirements for the majority of the skin immune index were higher than those for the growth (feed efficiency 1283.4 mg/kg diet) [19]. Similar results was found in other vitamins like VB7 and VC in grass carp [8, 18]. This result may illustrate that more choline or metabolites was needed for fish to resistance to bacterial infection.

5. Conclusions

Summary above, we reveal four primaries, innovative, and interesting results. The results exhibited that dietary choline (1) advanced contents of choline, betaine, and PC (not ACh) in grass carp skin (P < 0.05), down-regulated the mRNA abundance of choline transporter CHT1, CTL1, and CTL5 (rather than CTL2 and CTL4) indicating that dietary choline could increase the contents of choline and its metabolites as well as choline transporters expression in the skin; (2) reduced skin lesion and increased the contents of C3, IgM, C4, and the activities of ACP and LZ, advanced mucin2, LEAP-2B, hepcidin, and β-defensin mRNA abundance (rather than LEAP-2A), up-regulated the mRNA abundance of IL-1β, IFN-γ2, TNF-α, IL-6, IL-12P40, and IL-15 (rather than IL-12P35 and IL-17) in skin of juvenile grass carp (P < 0.05), down-regulated the mRNA abundance of TGF-β1, IL-4/13A, IL-4/13B IL-11 and IL-10 (rather than TGF-β2) in grass carp skin (P < 0.05) showed that choline enhanced the immune function of the skin; (3) down-regulated the mRNA abundance of IKKγ, IKKβ, c-Rel, NF-κBp65, and NF-κBp52 as well as protein level of NF-κBp65 in nucleus, up-regulated the mRNA and protein level of IkBα, advanced the mRNA abundance of STAT3b1, STAT3b2, JAK1, and JAK2 (rather than JAK3, STAT3a) as well as p-STAT3 Tyr705 protein level in grass carp skin (P < 0.05), indicating that choline protected immune function might relate to JAK/STAT3 and NF-κB singaling pathway in fish skin; In conclusion, choline enhanced the skin immune function be relevant to JAK/STAT3 and NF-κB signaling molecules in fish. Furthermore, based on the skin immune indices (C3 and IgM contents as well as ACP activities) the choline requirements for grass carp (9.28-108.97 g) were estimated to be 1475.81, 1364.24, and 1574.37 mg/kg diet, respectively.

Abbreviations

PC: phosphatidylcholine; ACP: acid phosphatase; LZ: lysozyme activity; JAK: Janus kinases; STAT: signal transducer and activator of transcription; IgM: Immunoglobulin M; ACP: Acid phosphatase; TNF-α: tumor necrosis factor-α; ACh:
acetylcholine; NF-κB: nuclear factor kappa-B; ECL: electrochemiluminescence; LEAP2: liver-expressed antimicrobial peptide2; IFN-γ: interferon γ; TGF-β: transforming growth factor-β; CTLs: choline transporter-like proteins; CHT1: high-affinity choline transporter; GM-CSF: macrophage colony stimulating factor;

Figures
Figure 1

Effects of dietary choline level (mg/kg diet) on skin rot morbidity of juvenile grass carp, Ctenopharyngodon idella, after infection with A. hydrophila. (A) 142.2 mg/kg diet. (B) 1589.3 mg/kg diet. *P-values underlined with a solid line indicate a significant linear dose response relationship (P < 0.05). Values are means, and standard error of the mean represented by vertical bars. N = 6*5 for each choline level. Values having different letters are significantly different (P < 0.05).

Figure 2

Effects of dietary choline on choline transporter gene level in the intestine of juvenile grass carp (Ctenopharyngodon idella) after infection with A. hydrophila. Data represent means of six fish in each group, error bars indicate S.D. Values having different letters are significantly different (P < 0.05).
Figure 3

Effects of dietary choline on parameters mRNA levels in the skin of grass carp after infection with A. hydrophila. This analysis was repeated 6 times with similar results. Data represent means of six fish in each group, error bars indicate S.D. Values having different letters are significantly different (P < 0.05).

Figure 4

Effects of dietary choline level (mg/kg diet) on relative expression of NF-κB signaling molecules in skin of juvenile grass carp (Ctenopharyngodon idella) after infection with A. hydrophila. Data represent means of six fish in each group, error bars indicate S.D. Values having different letters are significantly different (P < 0.05).
Figure 5

Effects of dietary choline level (mg/kg diet) on relative expression of JAK/STAT3 in skin of juvenile grass carp (Ctenopharyngodon idella) after infection with A. hydrophila. Data represent means of six fish in each group, error bars indicate S.D. Values having different letters are significantly different (P < 0.05).

Figure 6

Western blot analysis of p-STAT3Tyr705, NF-κBp65, and IκBα protein level in the skin of juvenile grass carp fed diet containing different levels of choline after infection with A. hydrophila. Values are means (6 replicates per group), and standard error represented by vertical bars. a,b,c Mean values with unlike letters were significantly different between treatments (P < 0.05)
Figure 7

Broken-line analysis of C3(A), IgM (B), and ACP content (C) in skin for grass carp (Ctenopharyngodon idella) fed diets containing graded levels of choline after infection with A. hydrophila.
