Urticaria is a disease characterized by erythematous, edematous, itchy and transient urticarial plaques, and covering the skin and mucous membranes. Also known as hives among people. It is a very common entity. 8.8–20% of individuals in the community experience an attack of urticaria at least once in their lifetime [1]. It can be seen in all ages and sexes but is slightly more common in young adults. In 40–50% of the patients, urticaria and angioedema are seen in combination, only urticaria or angioedema is seen in 40% and 20% of the people, respectively [2].

Classification (Table 1)

Acute spontaneous urticaria
It lasts <6 weeks [3].

Chronic spontaneous urticaria (CSU)
It recurs at least twice a week and lasts >6 weeks [3].

Physical urticaria (chronic inducible urticaria)
It emerges due to etiological factors as dermographism, cold, hot, vibration, pressure, and solar factors. It constitutes 20–30% of chronic urticaria [4].

Episodic chronic urticaria
It lasts >6 weeks but recurs <2 times per week [5].

It should be kept in mind that CSU and physical urticaria can be seen together. CSU is most commonly associated with dermatographic urticaria and late pressure urticaria [2].

Pathogenesis
The main mechanism in the formation of urticaria is the release of various mediators from mast cells. Type 1 immunoglobulin (Ig) E-dependent hypersensitivity reaction is seen in acute urticaria. The antigen entering the body binds to specific antibodies on mast cells and ba-
sophils, causing the release of many mediators, primarily histamine. As a result, edema due to erythema and increased permeability secondary to vasodilatation [6]. Mast cells cannot be restimulated until regranulation after degranulation, which explains why the urticaria plate does not reappear for several days on the region.

In chronic urticaria, the antigen entering the body binds to the IgE high affinity (FceRIα) Fc receptor located on the mast cells and circulating basophils in the skin and degranulation from these cells occurs. When the same antigen is encountered for the 2nd time, these IgE antibodies that are already present on the mast cells and basophils immediately bind to the antigen and develop an allergic reaction more quickly [7]. This shows us that autoimmunity is also important in chronic urticaria.

### Etiology

Many factors may be responsible in the etiology of the disease. Often, encountered factors include:

1. Medications: Any drug may cause urticaria. However, the most commonly encountered ones are penicillin, aspirin, nonsteroidal anti-inflammatory drugs, sulfonamides, thiazide diuretics, oral contraceptives, angiotensin-converting enzyme inhibitors, vitamins, codeine, morphine, curare and its derivatives, synthetic adrenocorticotropic hormone, and radiocontrast substances. It may manifest from 1–2 h to 15 days after oral intake. Urticaria related to the drugs given intravenously will occur immediately. While the drugs generally cause acute urticaria, they may cause emergence or exacerbation of CSU [8].

2. Foods: Foods often encountered as causes of urticaria include nuts, eggs, fish, seafood, chocolate, meat, cow’s milk, fruits (citrus fruits, grapes, plums, pineapples, bananas, apples, and strawberries), vegetables (tomatoes, garlic, onions, peas, beans, and carrots), mushrooms, fermented foods, spices, and spirits. Preservatives such as azo dyes, benzoic acid derivatives, and salicylates and food dyes are also important causative factors. Urticaria is usually seen 1–2 h after ingestion. Food-related urticarial rashes are more common in children [9]. Although it is accepted that foods have a place in the etiology of acute urticaria, their roles in the etiology of CSU have been not proven yet. It is thought that mostly pseudoallergens are involved in CSU, and therefore, diet is recommended for these patients [10].

3. Respiratory allergens: Pollen, mold spores, mites, animal dandruff, and hairs may cause urticaria when taken through the respiratory tract [11]. Smoking is also an important factor since it contains many chemicals and can worsen the urticaria, hives should be advised to stop smoking. Urticaria caused by respiratory allergens usually occurs immediately after contact.

4. Infections: Respiratory infections such as sinusitis, tonsillitis, dental abscesses, urinary tract infections, hepatitis, infectious mononucleosis, and parasites may cause urticaria [12]. Parasitoses are the cause of urticaria, especially in children.

5. Contact urticaria: Latex, cosmetics, and chemicals may cause urticaria by contact [13].

---

### Table 1. Classification of urticaria

| Type                                | Duration            | Characteristic features                                      |
|-------------------------------------|---------------------|--------------------------------------------------------------|
| Acute urticaria                     | Less than 6 weeks   | Recurs at least 2 times a week.                              |
| Chronic spontaneous urticaria       | More than 6 weeks   | Subtypes of urticaria according to triggering factors        |
| Chronic inducible urticaria (chronic physical urticaria) | More than 6 weeks | - Dermatographic urticaria                                   |
|                                     |                     | - Cold urticaria                                             |
|                                     |                     | - Heat urticaria                                             |
|                                     |                     | - Delayed pressure urticaria                                 |
|                                     |                     | - Solar urticaria                                            |
|                                     |                     | - Vibration urticaria                                        |
|                                     |                     | - Aquagenic urticaria                                        |
|                                     |                     | - Contact urticaria                                          |
|                                     |                     | - Cholinergic urticaria                                      |
| Episodic chronic urticaria          | Lasts more than 6 weeks | Recurs at least 2 times a week.                              |
6. Insect bites: They should be questioned, especially in children [14].

7. Psychogenic factors: Reasons such as stress, sadness, and depression may aggravate the preexisting urticaria and also induce urticaria [15].

8. Systemic diseases: They may cause especially chronic urticaria. The presence of thyroid diseases and rheumatic diseases such as systemic lupus erythematosus, lymphoma, leukemia, and carcinomas may be investigated as required. It should be noted that urticaria may occur also in pregnant women [11].

9. Physical factors: Urticaria may develop due to external factors such as pressure, hot, cold, and dermographism [13]. Urticaria secondary to pressure generally manifests an average of 3–4 h after exposure to pressure. Therefore, they are termed as delayed pressure urticaria.

10. Hereditary: Hereditary urticaria is seen in types of urticaria as angioedema and familial cold urticaria.

11. Idiopathic urticaria without any known cause may be also seen.

**Clinic Manifestations**

The urticarial plaque has three characteristics as characteristic redness, blistering, and itching. Sometimes, a burning sensation may accompany. Lesions can occur anywhere in the body and recover in approximately 2–3 h without leaving a trace. This spontaneous recovery can sometimes last up to 1 day.

In angioedema, especially in areas such as eyelid and lip mucosae, there is a sudden-onset skin swelling. Pain and burning sensation may be at the forefront rather than pruritus. The lesions regress spontaneously in about 72 h [16].

Dermographism is an erythema and edema occurring about 10–20 min after applying mechanical trauma to the skin. While this situation may be encountered in almost half of the population, if this region is itchy, then this entity is called dermatographic urticaria. This condition is seen in about 4% of the society [13].

**Diagnosis and Differential Diagnosis**

It is quite easy to diagnose based on clinical appearance and anamnesis. However, it is also sometimes confused with drug eruptions, viral rashes, connective tissue diseases, photosensitive diseases, urticaria pigmentosa, urticarial vasculitis, and a number of syndromic diseases [17].

It is very important to obtain detailed anamnesis from the urticaria patient to reach the etiology. The patient should be asked about the time of onset, development, localization of lesions, systemic complaints, food intake, stress, and regular or occasional medication use. There is no need for routine laboratory tests and allergy tests in acute urticaria. In a guideline published in the United States, it has been reported that if there is no evidence to support a diagnosis, then there is no need for laboratory examinations [3]. Just 25% of acute urticaria cases become chronic in time [18].

**Treatment**

**Basic steps in the treatment**

Elimination of detectable etiologic causes and avoiding triggers constitute the first step of treatment. If the patient expresses that the lesions occur in any condition, such as after a drug or food intake, he must avoid this situation. If there is a noticeable infectious condition, it should be treated.

In an important subgroup of patients with chronic urticaria, exacerbations triggered by physical stimuli occur. Training patients can help them avoid these stimuli or understand their symptoms. As an example, heat (hot showers and excessive humidity) is the common trigger of many people. Tight clothing or rubber bands may exacerbate symptoms. On the other hand, physical urticaria (dermographism, cold, hot, solar, cholinergic, pressure urticaria, etc.) developed with the stimuli of physical factors should be properly diagnosed and the stimulant should be eliminated.

Many drugs, especially aspirin and nonsteroidal anti-inflammatory drugs, may worsen symptoms. It is best to stay away from these drugs during this period [19].

A 4-week elimination diet is recommended for pseudoallergens thought to induce urticaria. Alcohol consumption is not recommended [20].

Concomitant stress, sleep disturbance, infections, premenstruation, and irregular antihistamine use may also aggravate the disease [15].

Rarely reported triggers are cigarette smoke, house dust mites, pollens, molds, and spores, and the patient should be informed about all these possible irritants [11].

After warning the patient about these issues, it is necessary to control the symptoms by suppressing the mediator release as the second step of the treatment.

In the treatment of urticaria (with or without angioedema), the focus should be on the immediate relief of pruritus and angioedema, if any. Approximately two-thirds of the cases of acute urticaria may be spontaneously confined and recover spontaneously.
H1 antihistamines
Antihistamines bind to histamine receptors and prevent the formation of pruritus and urticarial plaques [19]. The old generations of antihistamines are called the first generation and the new generations are called the second generation as follows:
1. First-generation agents (e.g., diphenhydramine, chlorpheniramine, hydroxyzine, cyclizine, dimenhydrinate, doxepin, doxamine, meclizine, promethazine, etc.)
2. Second-generation agents (cetirizine, loratadine, fexofenadine, desloratadine, levocetirizine, ebastine, and bilastine).

In the treatment, the second-generation H1 antihistamines are preferred. The first-generation H1 antihistamines are less preferred due to their significant sedation and side effects and short duration of action [21].

Antihistamines should be used on a daily basis but not in case of need. There is not yet sufficient data to suggest the most effective antihistamine in the treatment of CSU. The response to antihistamines and the possible side effects may vary from person to person.

The second-generation agents are more often preferred for both adults and children due to their low side effects, less drug-drug interaction, anticholinergic effects, longer duration of action, and higher safety [22].

Some patients may need higher dosages (up to 4 times) than standard doses for the control of urticarial symptoms and may experience drowsiness and sedation as side effects at high doses.

H2 antihistamines
Combination of H1 and H2 antihistamines may be more effective for acute urticaria than H1 antihistamines alone. However, the use of H2 in recent years has been removed from some guidelines [23]. H2 antihistamine options include ranitidine, nizatidine, famotidine, and cimetidine; however, cimetidine may increase levels of other drugs so it should be used with caution.

Systemic corticosteroids
Glucocorticoids do not inhibit mast cell degranulation, but they probably act by suppressing various inflammatory mechanisms. Glucocorticoids are not considered necessary for isolated urticaria. However, systemic glucocorticoids should be considered in cases with significant angioedema or if the symptoms persist for more than a few days and cannot be controlled by antihistamines. To control persistent and severe symptoms, systemic glucocorticoids may be added to antihistaminic therapy for a short period of time [19]. In adults, prednisone is given for an average of 5–10 days at daily doses of 30–60. In children, daily dose of prednisolone is 0.5–1 mg/kg (maximum 60 mg/day) which is tapered and discontinued within 5–7 days.

Cyclosporine
Compared with systemic corticosteroids, cyclosporine (5 mg/kg/day) has been reported to cause a more rapid and long-term remission. Clinical response rates are between 64% and 95%. When the duration of the treatment is completed, 50% of the patients may have remissions up to 9 months, but in some patients, relapses may occur after discontinuation of the treatment. In this case, maintenance therapy can be maintained at doses of 1.5–2 mg/kg/day for up to 2 years. The longer the duration of use, the higher the risk of side effects. It is used as an off-label drug for the treatment of CSU [24]. Although cyclosporine is a highly effective agent in the treatment of CSU, it should be preferred in patients with chronic urticaria resistant to high-dose antihistamines and omalizumab treatment, especially due to the risk of side effects that may occur during long-term use.

Omalizumab
Omalizumab, a monoclonal antibody (anti-IgE IgG) against IgE, is safe and effective for many patients, but it is too expensive and does not appear to have long-term disease-improving effects. Omalizumab reduces mast cell function and induces eosinophil apoptosis. It reduces cytokine release from basophils and migration of immune cells to tissue [25]. There are no studies directly comparing omalizumab with other treatments for resistant chronic urticaria.

There is no need for laboratory tests before and during the treatment. It is administered subcutaneously at a dose of 300 mg every 28 days for 6 months. It is effective in >80% of the patients. Omalizumab has also been reported to be effective in the treatment of other forms of urticaria, such as cold urticaria, solar urticaria, cholinergic urticaria, symptomatic dermatograph, and urticarial vasculitis [26].

Omalizumab is the only approved, effective, and reliable treatment option for CSU patients with persistent symptoms despite high-dose antihistamine therapy. In case of recurrence after 6 months of use, it can be used again without loss of efficacy [27].

Leukotriene receptor antagonists (LTRAs)
Zafirlukast and montelukast have not been studied in the treatment of acute urticaria. There is no double-
blind, placebo-controlled study with LTRAs. Systematic reviews indicate that they are more effective than placebo, but they are not highly recommended except for aspirin-induced urticaria cases. These drugs can be added to the treatment in step 2 and 3 [28].

**Other treatments**
The studies performed on the effectiveness of anti-inflammatory drugs such as dapsone, sulfasalazine, hydroxychloroquine, and colchicine, and studies on the effectiveness of immunosuppressive drugs such as methotrexate, mycophenolate mofetil, azathioprine, tacrolimus, mizoribine, and cyclophosphamide have low level of evidence [29, 30].

Several algorithms have been developed for the treatment of urticaria, which are summarized in Tables 2 and 3.

**Table 2.** Treatment algorithm for urticaria recommended by EAACI, GA2LEN, EDF, WAO [3]

| Step                  | Description |
|-----------------------|-------------|
| First-line            | Second-generation H1 antihistamines |
|                       | If symptoms persist more than 2 weeks |
| Second-line           | Increase the dose of second-generation antihistamines up to 4 times |
|                       | If symptoms persist for additional 1-4 weeks |
| Third-line            | Add omalizumab, montelukast or cyclosporine |
|                       | If symptoms cannot be controlled, corticosteroid therapy may be used for up to 10 days. |

**Table 3.** Treatment algorithm recommended by the Dermato-allergy Working Group of the Turkish Society of Dermatology and the Turkish Dermato-immunology and Allergy Association [8]

| Step | Description |
|------|-------------|
| 1    | Start with standard doses of second-generation antihistamines |
| 2    | If not under control 1-2 weeks later, increase the dose up to 4 times |
| 3    | If not under control 1-2 weeks later, switch to another antihistamine and use complete dose of the drug |
| 4    | If not under control 1-2 weeks later, switch to omalizumab for up to 24 weeks |
| 5    | If not under control 24 weeks later, increase the dose of omalizumab, switch to cyclosporine, or add to the existing treatment |
| 6    | If symptoms are still not under control 12 weeks later, other agents may be tried |

In selected cases, a leukotriene receptor antagonist may be added in Steps 2 and 3. During attacks, 0.5-1 mg/kg prednisolone or the equivalent systemic steroid may be prescribed.

**Treatment of urticaria in children**
New generation H1 antihistamines are recommended as the first choice in the treatment of urticaria as long-term safety profiles are better. The first-generation H1 antihistamines should not be used because they have strong sedative effects and decreased psychomotor ability of the children. Antihistaminic doses can be increased up to 2 times by taking the body weight of the children into account in cases refractory to standard doses [32].

There are no sufficient data on the use of LTRAs, cyclosporine, and omalizumab in the treatment of urticaria in children. Based on the treatment of adult urticaria, these agents may be used in addition to antihistamines in the third step of treatment. Evidence for the effectiveness and safety of omalizumab is increasing in children over 7 years of age. Pediatric patients who very well tolerated to monthly doses of 150–300 mg have been reported in the literature [33].

Cyclosporine has been used in children who are unresponsive to antihistaminic therapy as in adults and has been found to be highly effective [34].

Systemic corticosteroids can be used for a maximum of 10 days in pediatric patients experiencing angioedema attacks or widespread severe urticaria.

**Treatment of urticaria during pregnancy and lactation**
In the latest treatment guidelines, it is stated that the classical treatment algorithm proposed in the treatment of urticaria in pregnancy can be applied [8]. The pregnancy category B is indicated for chlorpheniramine, loratadine, cetirizine and levocetirizine is the pregnancy and category C for all other antihistamines. Immediate use of the first-generation H1 antihistamines with sedative effect has been found to be inconvenient as it causes
respiratory depression in the infant. All current guidelines emphasize that new generation antihistamines are more reliable in the treatment of urticaria in pregnant patients [8].

Pregnancy categories B and C are, respectively, assigned for LTRAs and cyclosporine.

There is no experience in the use of omalizumab in pregnancy. While using omalizumab, 169 pregnancies were reported in asthmatic patients, without increase in major anomalies. The FDA classified omalizumab in pregnancy category B [35].

Loratadine and cetrizine may be preferred during the breastfeeding period because they are found in very low amounts in breast milk [8].

Treatment of angioedema

Angioedema is not only seen as swelling in the skin and lips but sometimes also causes swelling in the tongue and larynx and may be life threatening. Therefore, treatment of angioedema is important. First of all, make sure that the patient’s airway is open and he/she is breathing comfortably. The standard treatment for patients without respiratory distress is H1 and H2 antihistamines and systemic corticosteroids [36]. If the patient has airway constriction or hypotension, the epinephrine should be administered intramuscularly at a dose of 0.2–0.5 mg [37]. The patient with respiratory distress should be immediately referred to a more experienced medical center after taking the necessary precautions.

Conclusion

Urticaria is an acute and chronic itchy rash that can be quite irritating. Angioedema may accompany urticaria, and rarely, it may be fatal. Although many etiologic factors such as infections, drugs, and foods are blamed in their etiology, they are often idiopathic. In the treatment of patients, if there is a detectable etiologic or trigger factor, it should be avoided and the patient should be warned for the possible existence of physical urticaria. Although antihistamines are used in the first step treatment, a wide variety of agents have been used, including corticosteroids, omalizumab, and cyclosporine. In medicine, there is no disease, there is a patient, and every patient should be treated with appropriate care. Nevertheless, it should be kept in mind that it is still a challenging disease for both the patient and the physician.
