Abstract

The beta polytope $P_{n,d}^{\beta}$ is the convex hull of $n$ i.i.d. random points distributed in the unit ball of $\mathbb{R}^d$ according to a density proportional to $(1 - \|x\|^2)^\beta$ if $\beta > -1$ (in particular, $\beta = 0$ corresponds to the uniform distribution in the ball), or uniformly on the unit sphere if $\beta = -1$. We show that the expected normalized volumes of high-dimensional beta polytopes exhibit a phase transition and we describe its shape. We derive analogous results for the intrinsic volumes of beta polytopes and, when $\beta = 0$, their number of vertices.

Keywords. Beta distribution, convex hull, expected volume, phase transition, random polytopes.

1 Introduction

In the last few years there has been an increasing interest in the study of high-dimensional random convex hulls, see \cite{2,4,6,8,17} for example. A common way to construct such objects is described by the following general principle. For every couple of natural numbers $d$ and $n$ with $n > d$, and any measure $\mu$ with compact support on $\mathbb{R}^d$, we consider the convex hull $P_{n,d}^\mu$ of $n$ i.i.d. random points distributed with respect to $\mu$. Clearly $P_{n,d}^\mu \subseteq \text{conv}(\text{supp}(\mu))$, where $\text{conv}$ denotes the convex hull operator and $\text{supp}(\mu)$ the support of $\mu$. Therefore, if $n = n(d)$ and $\mu = \mu(d)$, then the sequence of expected normalised volumes

$$\frac{\mathbb{E}\text{vol}_d(P_{n,d}^\mu)}{\text{vol}_d(\text{conv}(\text{supp}(\mu)))}, \quad d \in \{2, 3, \ldots\}, \quad (1)$$

takes values in the interval $[0, 1]$.

It is clear that if $n$ grows extremely slowly, the slowest being $n = d + 1$, then the expectation of the above ratio tends to 0, and that on the other hand it will go to 1 if $n$ grows sufficiently fast. Thus, between these extreme regimes there is a family of regimes where a transition happens. An interesting problem is to identify them. Namely, one would like to answer the following questions:

(Q1) What are the regimes $n = n(d)$ where the transition happens?

(Q2) For such regimes, what is the shape of the transition?
The first question has been answered for a variety of families of distributions. Dyer, Füredi and McDiarmid considered in [6] the setting where \( \mu \) if the uniform discrete measure on the \( 2^d \) vertices of the unit cube \([-1,1]^d\) and showed that such regimes satisfy \( n^{1/d} \to 2/\sqrt{e} \), meaning that if \( n^{1/d} < 2/\sqrt{e} - \varepsilon \) (resp. \( > 2/\sqrt{e} + \varepsilon \)), for all \( d \) sufficiently large and for a fixed \( \varepsilon > 0 \), then the sequence \((\varepsilon)\) tends to 0 (resp. 1). Gatzouras and Giannopoulos extended this result in [8] to the general setting where \( \mu \) is the product \( \mu_1^\otimes d \) of \( d \) copies of a fixed symmetric measure \( \mu_1 \) with compact support in \( \mathbb{R} \). The criterion in this setting has the same form, namely \( n^{1/d} \to c \) where \( c > 0 \) is a constant which can be expressed in term of \( \mu_1 \). In [17], Pivovarov proved that if \( \mu \) is the uniform distribution on the unit ball \( \mathbb{B}^d \), then the regimes answering \((Q1)\) satisfy

\[
\frac{\log n}{d \log d} \to \frac{1}{2}.
\]

The latter result has been extended in [2] to the class of so-called beta distributions which have recently attracted a considerable attraction in stochastic geometry \([1, 3, 5, 9, 10, 11, 12, 13, 14, 15, 16, 18]\). These distributions are described by their density, which is proportional to \((1-\|x\|^2)^\beta 1(\|x\|<1)\), where \( \|\cdot\| \) denotes the Euclidean norm and where \( \beta > -1 \) is a parameter which might depend on \( d \). For example, \( \beta = 0 \) generates the uniform distribution on the Euclidean unit ball. We extend this family of distributions by defining the beta distribution with \( \beta = -1 \) to be the uniform distribution on the unit sphere. For such distributions, that we denote here by \( \mu_\beta \), it was shown in [2] that

\[
\frac{\log n}{(d + 2\beta) \log d} \to \frac{1}{2}
\]

is a criterion answering \((Q1)\). In particular, for any \( \varepsilon > 0 \),

\[
\lim_{d \to \infty} \frac{\mathbb{E} \text{vol}_d(P_{n,d}^\beta)}{\text{vol}_d(\mathbb{B}^d)} = \begin{cases} 
0 & \text{if } n \leq \exp(\varepsilon)(\frac{d}{2} + \beta) \log d), \\
1 & \text{if } n \geq \exp(\varepsilon)(\frac{d}{2} + \beta) \log d),
\end{cases}
\]

where we use \( P_{n,d}^\beta \) as a shorthand for \( P_{n,d}^{\mu_\beta} \). This threshold phenomenon was obtained by generalizing Pivovarov’s arguments. In the present paper we use instead an integral representation of the expected volume of beta polytopes obtained by Kabluchko, Temesvari and Thäle in [14], see Theorem 2.1 below for a statement of this formula. By studying carefully this integral we will be able to refine (2) by also answering \((Q2)\) for the beta polytopes model.

Namely, we will show that whenever \( x \) is a positive constant and the number \( n \) of random points grows like \( \exp(\varepsilon)(\frac{d}{2} + \beta) \log d) \), then

\[
\frac{\mathbb{E} \text{vol}_d(P_{n,d}^\beta)}{\text{vol}_d(\mathbb{B}^d)} \to e^{-x} \in (0,1),
\]

as \( d \) tends to infinity.

The rest of the paper is structured as follows. In the next section we introduce the required notation and present some preliminaries. In Section 3 we state the main theorem and derive some simple but interesting corollaries. Finally, Section 4 is dedicated to the proof of the theorem and its corollaries.

## 2 Notation and preliminaries

For \( d \in \mathbb{N} \geq 2 \), we denote by \( \mathbb{B}^d \) the Euclidean unit ball in \( \mathbb{R}^d \) and by \( \mathbb{S}^{d-1} \) its boundary. We denote by \( \text{vol}_d \) the Lebesgue measure on \( \mathbb{R}^d \) and we write \( \kappa_d := \text{vol}_d(\mathbb{B}^d) = \pi^{d/2}/\Gamma(1+d/2) \).
For two sequences \( a(d) \) and \( b(d) \) we use the notation \( a \sim b \), respectively \( a = o(b) \), to mean that the ratio \( a(d)/b(d) \) tends to 1, respectively 0, as \( d \to \infty \).

Given a convex body \( K \subset \mathbb{R}^d \) and a number \( k \in \{0, \ldots, d\} \), the \( k \)-th intrinsic volume of \( K \), denoted by \( V_k(K) \), is the geometric functional defined by means of the Steiner formula, namely

\[
\text{vol}_d(K + t\mathbb{B}^d) = \sum_{k=0}^{d} t^{d-k} \kappa_{d-k} V_k(K),
\]

for every \( t \geq 0 \). In particular, it holds that \( V_d = \text{vol}_d \) and that \( V_{d-1}(K) \) is half the surface area of \( K \). Moreover, whenever \( K \) is a polytope, i.e. the convex hull of a finite number of points, then we indicate with \( f_0(K) \) the number of its vertices.

We call beta distribution with parameter \( \beta > -1 \) the continuous probability measure on \( \mathbb{R}^d \) with density

\[
x \mapsto \frac{\Gamma\left(\frac{d}{2} + \beta + 1\right)}{\pi^{\frac{d}{2}} \Gamma(\beta + 1)} (1 - \|x\|^2)^\beta, \quad \|x\| < 1,
\]

and 0 everywhere else. In particular, the beta distribution with \( \beta = 0 \) is just the uniform distribution in the Euclidean unit ball. We also say that the beta distribution with parameter \( \beta = -1 \) is the uniform distribution on the Euclidean sphere \( \mathbb{S}^{d-1} \); this is justified by the fact that the beta distributions with parameters \( \beta > -1 \) converge weakly to the uniform probability distribution on the sphere as \( \beta \to -1 \) (a proof of this fact can be found in [14]).

Let \( X_1, \ldots, X_n \) be i.i.d. random points in \( \mathbb{R}^d \) distributed according to the beta distribution with parameter \( \beta \). We construct the beta-polytope \( P_{\beta}^{n,d} \) as

\[
P_{\beta}^{n,d} := \text{conv}(\{X_1, \ldots, X_n\}) \subset \mathbb{B}^d.
\]

We introduce the non-negative quantities

\[
F_{z-1}(h) := 2z c_z \int_{-1}^{h} (1 - s^2)^{z-1} ds, \quad h \in [-1, 1], z > 0.
\]

Note that \( F_{z-1} \) takes values in \([0, 1]\).

An explicit representation of the expected volume of \( P_{\beta}^{n,d} \) was proved in [14, Theorem 2.1 for the case \( \beta > -1 \) and Corollary 3.9 for \( \beta = -1 \)] and can be stated as follows.

**Theorem 2.1.** Let

\[
K_{\beta}^{n,d} = \frac{(d+1)\kappa_d}{2d^d n^{\frac{d}{2}}} \left( \frac{n}{d+1} \right)^{\beta + \frac{d}{2}} \left( \frac{\Gamma\left(\frac{d}{2} + \beta\right)}{\Gamma\left(\frac{d+1}{2} + \beta\right)} \right)^{d+1}
\]

and \( q = (d+1)(\beta - \frac{1}{2}) + \frac{d}{2}(d+3) \). Then,

\[
E \text{vol}_d(P_{\beta}^{n,d}) = K_{\beta}^{n,d} \int_{-1}^{1} (1 - h^2)^q F_{\beta + \frac{d}{2}}^{\frac{d}{2}}(h)^{n-d-1} dh.
\]

### 3 The main result and related corollaries

We want to prove the following statement.
Theorem 3.1. Fix \( x \in (0, +\infty) \) and consider any sequence \( \beta = \beta(d) \geq -1 \). Let \( n = n(d) \) be a sequence of natural numbers of the form

\[
 n = \left( \frac{d}{2x + o(1)} \right)^{d/2+\beta},
\]

where \( o(1) \) is a sequence converging to 0 as \( d \to \infty \). Then,

\[
 \lim_{d \to \infty} \frac{E \text{vol}_d(P_{n,d}^\beta)}{\text{vol}_d(B^d)} = e^{-x}.
\]

Remark 1. Taking into account both Theorem 3.1 and the threshold established in [2], we can state that, for any sequence of natural numbers \( n = n(d) \),

\[
 \lim_{d \to \infty} \frac{E \text{vol}_d(P_{n,d}^\beta)}{\text{vol}_d(B^d)} = \lim_{d \to \infty} \exp\left( -\frac{d}{2} \exp\left( -\frac{2\log n}{d + 2\beta} \right) \right),
\]

whenever the right hand side exists.

The first consequence of Theorem 3.1 that we mention is about the ratio of expected intrinsic volumes of \( P_{n,d}^\beta \).

Corollary 3.2. Under the same hypotheses of Theorem 3.1 on \( x \) and \( \beta \), let \( k = k(d) \in \{1, \ldots, d\} \) be a diverging sequence of natural numbers as \( d \to \infty \) and \( n = n(d) \) be a sequence of natural numbers of the form

\[
 n = \left( \frac{k}{2x + o(1)} \right)^{d/2+\beta},
\]

where \( o(1) \) is a sequence converging to 0 as \( d \to \infty \). Then,

\[
 \lim_{d \to \infty} \frac{E V_k(P_{n,d}^\beta)}{V_k(B^d)} = e^{-x}.
\]

The second consequence provides an exact asymptotics on the expected number of vertices that the beta-polytope has in the phase transition.

Corollary 3.3. Under the same assumptions as in Theorem 3.1, fix \( \beta = 0 \). Then the asymptotic behavior of the expected number of vertices \( P_{n,d}^0 \) is given by

\[
 E f_0(P_{n,d}^0) \sim n(1 - e^{-x}),
\]

as \( d \to \infty \).

4 Proofs

In view of formula (4), it is convenient for our purposes to change the variables \( d \) and \( n \) in the following way:

\[
 D := \frac{d + 1}{2} \in \{3/2, 2, \ldots\}, \\
 N := n - d - 1 \in \{0, 1, \ldots\}.
\]

This makes the constant in front of the integral (4) become

\[
 K := K_{N+2D,2D-1} = 4D(D + \beta) \binom{N + 2D}{2D} c_{2D+\beta}^{2D+\beta} K_d,
\]

(7)
while the integral itself is given by

$$\int_{1}^{1} (1 - h^2)^{2D(D+\beta)-1} F_{D+\beta-1}(h)^N \, dh.$$ 

We study the behaviour of integrals of the form

$$I^b_a = I^b_a(N, D, \beta) := \int_{a}^{b} (1 - h^2)^{2D(D+\beta)-1} F_{D+\beta-1}(h)^N \, dh,$$

for $a, b \in [-1,1]$ and $\beta \geq -1$, and $D$ diverges. Indeed, Theorem 2.1 can be reformulated as

$$\mathbb{E} \text{vol}_d(P^\beta n,d) = K I_{+1}^{\pm 1}.$$ (9)

We start by reducing the problem to the study of a more precise speed of growth of the number of random points.

**Lemma 4.1.** It is sufficient to prove Theorem 3.1 for all the integers $N = N(D)$ such that

$$N \sim \left(\frac{D}{x}\right)^{D+\beta} \sqrt{1 + \frac{\beta}{D}},$$

as $D \to \infty$, with $x \in (0, +\infty)$ and $\beta = \beta(D) \in [-1, +\infty)$.

**Proof.** Assume that if $N \sim D^{+\beta}x^{-D-\beta} \sqrt{1 + \beta/D}$ then, for $d = 2D - 1$ and $n = N + d + 1$, it holds

$$\lim_{d \to \infty} \frac{\mathbb{E} \text{vol}_d(P^\beta n,d)}{\text{vol}_d(\mathbb{B}^d)} = e^{-x}.$$ 

Notice that if $n$ is as in Equation (5), then

$$N = \left(\frac{2D - 1}{2x + o(1)}\right)^{D+\beta-1/2} - 2D = \left(\frac{D}{x + o(1)}\right)^{D+\beta-1/2},$$

where the equalities above follow, respectively, from the definition of $N$ and $D$, and trivial simplifications. Therefore

$$N = \left(\frac{D}{x + o(1)}\right)^{1/(D+\beta)} \left(\sqrt{\frac{x/D}{1 + \beta/D}}\right)^{D+\beta} \sqrt{1 + \frac{\beta}{D}} = \left(\frac{D}{x + o(1)}\right)^{D+\beta} \sqrt{1 + \frac{\beta}{D}}.$$ 

Now, fix an arbitrary small constant $\varepsilon > 0$. There exists $D$ large enough such that:

$$N^- = \left[\left(\frac{D}{x + \varepsilon}\right)^{D+\beta} \sqrt{1 + \frac{\beta}{D}}\right] \leq N \leq \left[\left(\frac{D}{x - \varepsilon}\right)^{D+\beta} \sqrt{1 + \frac{\beta}{D}}\right] = N^+.$$ 

Using $N^-$ and $N^+$ gives $e^{-x-\varepsilon}$ and $e^{-x+\varepsilon}$, for the respective limits of the ratio, by hypothesis. This allows us to deduce the claimed statement, because of the monotonicity of $n \mapsto \mathbb{E} \text{vol}_d(P^\beta n,d)$ for any $d$ fixed, the arbitrariness of $\varepsilon$ and the continuity of the exponential map.

In view of (9) and Lemma 4.1, we want to show that

$$\lim_{d \to \infty} \frac{K I_{+1}^{\pm 1}}{K_d} = e^{-x},$$

whenever

$$N \sim \left(\frac{D}{x}\right)^{D+\beta} \sqrt{1 + \frac{\beta}{D}}.$$ (11)
Our strategy is to find convenient \( a = a(d) \), \( b = b(d) \) \( \in (0, 1) \) in such a way that

\[
\lim_{d \to \infty} \frac{K_1^{a}}{\kappa_d} = 0, \quad \lim_{d \to \infty} \frac{K_1^{b}}{\kappa_d} = e^{-x} \quad \lim_{d \to \infty} \frac{K_1^{1}}{\kappa_d} = 0.
\]

In order to do so, we first gather some useful facts in the next four Lemmas. We start with an inequality on the ratio of Gamma functions due to Wendel [19].

**Lemma 4.2.** For \( z > 0 \) it holds that

\[
\frac{1}{\sqrt{z + 1/2}} \leq \frac{\Gamma(z + 1/2)}{\Gamma(z + 1)} \leq \frac{1}{\sqrt{z}}.
\]

By the previous lemma, it holds

\[
c_{D+\beta} \leq \frac{1}{2 \sqrt{\pi(D + \beta)}} \quad \text{and} \quad c_{D+\beta} \sim \frac{1}{2 \sqrt{\pi(D + \beta)}},
\]

as \( D \to \infty \). Notice that this implies that if \( N \) is chosen as in Lemma 4.1, then

\[
2\sqrt{\pi N c_{D+\beta}} \sim D^{D+\beta-\frac{1}{2}} x^{-D-\beta}. \tag{12}
\]

**Lemma 4.3.** For all \( m \geq 1 \) and all \( y \in (-\infty, m) \):

\[
\exp \left( - \frac{y^2}{m - y} \right) \leq e^y \left( 1 - \frac{y}{m} \right)^m \leq 1. \tag{13}
\]

In particular, if \( y = y(m) \) is such that \( y^2/m \to 0 \) as \( m \to \infty \), then

\[
\left( 1 - \frac{y}{m} \right)^m \sim e^{-y}, \tag{14}
\]

as \( m \to \infty \).

**Proof.** It is well known that

\[
\frac{z}{1 + z} \leq \log(1 + z) \leq z, \quad z \in (-1, \infty).
\]

We use it with \( z = -y/m > -1 \). Applying the increasing mapping \( \exp(m \cdot) \) on both sides of the inequality we get:

\[
\exp \left( - \frac{my}{m - y} \right) \leq \left( 1 - \frac{y}{m} \right)^m \leq \exp(-y).
\]

The fact that \( \frac{my}{m-y} = y + \frac{y^2}{m-y} \) yields the result. \( \square \)

**Lemma 4.4.** For \( D \) large enough, \( \frac{K}{\kappa_d} \leq (D/x)^{2D(D+\beta)} \).

**Proof.** Recall from (7) that

\[
\frac{K}{\kappa_d} = 4D(D + \beta) \left( \frac{N + 2D}{2D} \right)^{2D(D+\beta)}.
\]

We start by bounding the binomial coefficient. Using the bounds \( \binom{k+\ell}{k} \leq (k + \ell)^k/k! \) and \( k! \geq (k/e)^k \), with \( k = 2D \) and \( \ell = N \), we note that

\[
\binom{N + 2D}{2D} \leq \left( \frac{e(N + 2D)}{2D} \right)^{2D} = \left( \frac{eN}{2D} \right)^{2D} e^{o(1)},
\]
where the last equality is due to the RHS inequality of eq. (13). Indeed
\[ 1 \leq \left( \frac{N + 2D}{N} \right)^{2D} = \left( 1 + \frac{o(1)}{2D} \right)^{2D} \leq e^{o(1)}. \]

Also by Lemma 4.2, we know that \( c_{D+\beta} \leq 1/(2\sqrt{\pi(D + \beta)}) \).
Thus for \( N = (D/x)^{D+\beta}e^{o(1)} \sqrt{1 + \beta/D} \) we get
\[
\frac{K}{K_d} \leq 4D(D + \beta) \left( \frac{e(D/x)^{D+\beta}e^{o(1)}}{4D\sqrt{\pi(D + \beta)}} \right)^{2D} \leq \frac{e^{1+o(1)}}{4D\sqrt{\pi}} \frac{4D}{(D + \beta)^{D-1}} \left( \frac{D}{x} \right)^{2D(D+\beta)},
\]

where the last bound holds for \( D \) large enough. This gives the conclusion. \( \square \)

The following inequality provides a useful approximation of the functions \( F_{z-1} \).

**Lemma 4.5.** For any \( h \in (0, 1) \) and \( z > 0 \),
\[
1 - \frac{1 - h^2}{2h^2(z + 1)} \leq \frac{h(1 - F_{z-1}(h))}{cz(1 - h^2)^z} \leq 1.
\]

**Proof.** Recall that for \( h \in (0, 1) \), the function \( F_{z-1}(h) \) is defined by
\[
F_{z-1}(h) = 2cz \int_{-1}^{h} (1 - s^2)^{z-1} \, ds
\]
and in particular for \( h = 1 \) this simplifies as \( F_{z-1}(1) = 1 \). Thus
\[
\frac{1 - F_{z-1}(h)}{cz} = 2z \int_{h}^{1} (1 - s^2)^{z-1} \, ds.
\]

We apply the substitution \( t = \frac{s^2 - h^2}{1 - h^2} \) to get
\[
\frac{1 - F_{z-1}(h)}{cz} = 2z \int_{0}^{1} \left[ 1 - h^2 - (1 - h^2)t \right]^{z-1} \frac{1 - h^2}{2\sqrt{h^2 + (1 - h^2)t}} \, dt.
\]

Multiplying by \( h/(1 - h^2)^z \) gives
\[
\frac{h(1 - F_{z-1}(h))}{cz(1 - h^2)^z} = z \int_{0}^{1} (1 - t)^{z-1} \frac{1}{\sqrt{1 + \frac{h^2 t}{h^2 t}}} \, dt.
\]

The fraction in the last integrand makes the computation delicate and this is the step where we introduce the approximation given by
\[
1 - \frac{1 - h^2}{2h^2 - t} \leq \frac{1}{\sqrt{1 + \frac{h^2 t}{h^2 t}}} \leq 1, \quad h, t \in (0, 1).
\]

These bounds follow from the fact that for any \( u \geq 0 \), \((1 + u)^{-1/2} \geq 1 - u/2 \).

We get the upper bound of Lemma 4.5 by plugging the upper bound of (16) in (15) and using the fact that \( \int_{0}^{1} (1 - t)^{z-1} \, dt = 1/z \).

It remains to show the lower bound of the lemma. Using the lower bound of (16) and (15), we get
\[
\frac{h(1 - F_{z-1}(h))}{cz(1 - h^2)^z} \geq z \int_{0}^{1} (1 - t)^{z-1} \, dt - \frac{1 - h^2}{2h^2} z \int_{0}^{1} (1 - t)^{z-1} \, dt.
\]

The two last integrals evaluate nicely. As we have already mentioned, the first equals \( 1/z \). The second is the beta function \( B(z, 2) = \Gamma(z)\Gamma(2)/\Gamma(z + 2) = 1/[z(z + 1)] \). The lower bound of lemma follows directly. \( \square \)
We are now ready to prove the main result.

**Proof of Theorem 3.1.** Choosing \( z = D + \beta \) in Lemma 4.5, we get that for any \( a, b \in (0, 1) \) with \( a < b \), and any \( h \in [a, b] \), it holds that

\[
1 - Ac_{D+\beta}(1 - h^2)^{D+\beta} \leq F_{D+\beta-1}(h) \leq 1 - Bc_{D+\beta}(1 - h^2)^{D+\beta},
\]

where \( A := \frac{1}{a} \) and \( B := \frac{1}{b}(1 - \frac{a^2}{2\alpha(D+\beta)}) \). This inequality can be used to bound \( I_a^b \) on both sides. On the left-hand side we perform the change of variable

\[
t = NAc_{D+\beta}(1 - h^2)^{D+\beta}.
\]

The Jacobian of this transformation is such that

\[
(1 - h^2)^{2(D+\beta)-1} dh = \frac{(1 - h^2)^{(2D-1)(D+\beta)}}{2h(D+\beta)Na_{D+\beta}} dt = \frac{t^{2D-1}}{-2h(D+\beta)(NAc_{D+\beta})^{2D}} dt.
\]

We perform an analogous change of variable on the right-hand side, this time replacing \( A \) by \( B \). We also use \( 1/b \leq 1/h \leq 1/a \). Hence, we get

\[
\frac{1}{2b(D+\beta)(NAc_{D+\beta})^{2D}} \int_N^{Na(D+\beta)/(1-b^2)^{D+\beta}} t^{2D-1} \left( 1 - \frac{t}{N} \right) dt
\]

\[
\leq 1_a^b
\]

\[
\leq \frac{1}{2a(D+\beta)(NBc_{D+\beta})^{2D}} \int_{NBc_{D+\beta}(1-b^2)^{D+\beta}}^{NBc_{D+\beta}(1-a^2)^{D+\beta}} t^{2D-1} \left( 1 - \frac{t}{N} \right) dt,
\]

therefore, multiplying all terms by \( K/k_d \), we get

\[
\frac{1}{bA^{2D}} \left( \frac{N + 2D}{2D} \right)^{2D} \int_N^{Na(D+\beta)/(1-b^2)^{D+\beta}} t^{2D-1} \left( 1 - \frac{t}{N} \right) dt
\]

\[
\leq \frac{Kt^b}{k_d}
\]

\[
\leq \frac{1}{aB^{2D}} \left( \frac{N + 2D}{2D} \right)^{2D} \int_{NBc_{D+\beta}(1-b^2)^{D+\beta}}^{NBc_{D+\beta}(1-a^2)^{D+\beta}} t^{2D-1} \left( 1 - \frac{t}{N} \right) dt.
\]

(17)

By Lemma 4.3 and the fact that the mapping \( t \mapsto e^{-t^2} \) is decreasing for \( t \in (0, N) \), we get that for \( t \in [NBc_{D+\beta}(1-b^2)^{D+\beta}, NA_{D+\beta}(1-a^2)^{D+\beta}] \),

\[
r_{N,D,a} := \exp\left( -N \cdot \frac{t^2}{1 - Ac_{D+\beta}(1 - a^2)^{D+\beta}} \right) \leq e^t \left( 1 - \frac{t}{N} \right)^N \leq 1,
\]

provided that \( Ac_{D+\beta}(1-b^2)^{D+\beta} < 1 \), which will be justified later with a particular choice of \( a \) and \( b \).

Using the last two facts, from (17) we get

\[
1 \leq (2D-1)! \left( \frac{N + 2D}{2D} \right)^{2D} \leq \left( 1 + \frac{2D}{N} \right)^{2D} =: s_{N,d}
\]

Hence, we get from (17)

\[
\frac{r_{N,D,a}}{bA^{2D}} \left( \frac{N + 2D}{2D} \right)^{2D} \int_N^{Na(D+\beta)/(1-b^2)^{D+\beta}} t^{2D-1} e^{-t} dt \leq \frac{Kt^b}{k_d}
\]

\[
\leq \frac{s_{N,D}}{aB^{2D}} \left( \frac{N + 2D}{2D} \right)^{2D} \int_{NBc_{D+\beta}(1-b^2)^{D+\beta}}^{NBc_{D+\beta}(1-a^2)^{D+\beta}} t^{2D-1} e^{-t} dt.
\]

(18)
Now note that \( t^{2D-1}e^{-t}/(2D-1)! \) is the probability density function of random variable with a \( \Gamma(2D,1) \) probability distribution, hence also of a sum of \( 2D \) independent copies \( (E_i)_{i=1}^{2D} \) of an exponentially distributed random variable with mean 1. Therefore, by the weak law of large numbers,

\[
\lim_{D \to \infty} \frac{1}{(2D-1)!} \int_{NAC_{D+\beta}(1-a^2)^{D+\beta}}^{} t^{2D-1}e^{-t} \, dt = \lim_{D \to \infty} P \left( NAC_{D+\beta}(1-b^2)^{D+\beta} \leq \sum_{i=1}^{2D} E_i \leq NAC_{D+\beta}(1-a^2)^{D+\beta} \right) = 1
\]

granted that there exists an \( \varepsilon > 0 \) such that definitely

\[
NAC_{D+\beta}(1-a^2)^{D+\beta} > (1+\varepsilon)2D, \\
NAC_{D+\beta}(1-b^2)^{D+\beta} < (1-\varepsilon)2D.
\]  

(19)

Now assume without loss of generality that \( D > x \) and define the following quantities in \((0,1)\):

\[
a := \sqrt{1 - x D \left( 1 + \log \left( \frac{D^2(D+\beta)}{D+\beta} \right) \right)}, \\
b := \sqrt{1 - x D}.
\]

Since \( a^{2D} = \left(1 - \frac{\beta}{D} \left(1 + \log \left( \frac{D^2(D+\beta)}{D+\beta} \right) \right)\right)^D \) and \( x \left(1 + \frac{\log(D^2(D+\beta))}{D+\beta}\right) \to x \) as \( D \to \infty \) then, by (14),

\[a^{2D} \sim e^{-x}.
\]

Analogously, \( b^{2D} \sim e^{-x} \), as \( D \to \infty \). Moreover

\[(1-a^2)^{D+\beta} = \left( \frac{x}{D} \right)^{D+\beta} \left(1 + \log \left( \frac{D^2(D+\beta)}{D+\beta} \right) \right)^{D+\beta}.
\]

Using \( m = D + \beta \) and \( y = -\log \left( D^2(D+\beta) \right) \) in Lemma 4.3, since \( y^2/m \to 0 \) as \( D \to \infty \), we get

\[
\left(1 + \frac{\log(D^2(D+\beta))}{D+\beta}\right)^{D+\beta} \sim e^{\log(D^2(D+\beta))} = D^2(D+\beta),
\]

as \( D \to \infty \).

Summing up what we just computed above, we get for \( D \to \infty \),

\[
(1-a^2)^{D+\beta} \sim x^{D+\beta} D^{2-D-\beta}(D+\beta), \\
(1-b^2)^{D+\beta} \sim x^{D+\beta} D^{-D-\beta}.
\]

(21)

Recall that \( A = 1/a \to 1 \) and \( N_{CD+\beta} \sim D^{D+\beta-\frac{1}{2}}/(2\sqrt{\pi}x^{D+\beta}) \), as noted in equation (12). Thus,

\[
NAC_{D+\beta}(1-a^2)^{D+\beta} \sim \frac{1}{2\sqrt{\pi}} D^{3/2}(D+\beta), \\
NAC_{D+\beta}(1-b^2)^{D+\beta} \sim \frac{1}{2\sqrt{\pi}} D^{-1/2},
\]

(22)

and, in particular, the assumptions (19) are verified.
Moreover, in such a case, as $D \to \infty$,
\[
  r_{N,D,a} A^{-2D} = r_{N,D,a} a^{2D} \sim 1 \cdot e^{-x} = e^{-x},
\]
where the asymptotics $r_{N,D,a} \sim 1$ is a consequence of (21).

We proved that if assumptions (11) and (20) are satisfied then the left hand side of (18) tends to $e^{-x}$. It is a simple check to see that everything holds in the same way for the right-hand side, since we only replace $A$ by $B$. Indeed, as far as the prefactor of the integral is concerned,
\[
  s_{N,D} B^{-2D} = \left( 1 + \frac{2D}{N} \right)^{2D} b^{2D} \left( 1 - \frac{1 - a^2}{2a^2(D + \beta)} \right)^{-2D} \sim 1 \cdot e^{-x} \cdot 1 = e^{-x},
\]

since $\frac{1-a^2}{2a^2} = o(1)$. Hence, both the upper and the lower bound for $K_{I_1} / \kappa_d$ have the same asymptotics, which allows to conclude that
\[
  \frac{K_{I_1}}{\kappa_d} \sim e^{-x},
\]
as $d \to \infty$.

With Lemmas 4.6 and 4.7 below we have that under the same conditions,
\[
  \frac{K_{I_1}}{\kappa_d} \to 0 \quad \text{and} \quad \frac{K_{I_1}}{\kappa_d} \to 0,
\]
as $d \to \infty$, which yields Equation (10).

**Lemma 4.6.** If $a$ is chosen as in (20), then $\frac{K_{I_1}}{\kappa_d} \to 0$ as $d \to \infty$.

**Proof.** Since $F_{D+\beta-1}$ is increasing, then
\[
  I_{-1}^{a} \leq \int_{-1}^{1} (1 - h^2)^{2D(D+\beta)-1} dh F_{D+\beta-1}(a)^N
  = \sqrt{\pi} \left( \frac{\Gamma(2D(D+\beta))}{\Gamma(2D(D+\beta)+1/2)} \right) F_{D+\beta-1}(a)^N \leq F_{D+\beta-1}(a)^N,
\]
where the last equation holds for every $D$ large enough. By Lemma 4.5,
\[
  F_{D+\beta-1}(a) \leq 1 - \frac{cD+\beta}{a} (1 - a^2)^{D+\beta} \left( 1 - \frac{1 - a^2}{2a^2(D + \beta + 1)} \right)
\]
so that
\[
  F_{D+\beta-1}(a)^N \leq \exp \left( -N \frac{cD+\beta}{a} (1 - a^2)^{D+\beta} \left( 1 - \frac{1 - a^2}{2a^2(D + \beta + 1)} \right) \right). \tag{23}
\]
Recall that $a \to 1$, thus (22) gives us that
\[
  N \frac{cD+\beta}{a} (1 - a^2)^{D+\beta} \left( 1 - \frac{1 - a^2}{2a^2(D + \beta + 1)} \right) \sim \frac{1}{2\sqrt{\pi}} D^{3/2}(D + \beta).
\]
Combining the above estimates with the bound of $K/\kappa_d$ obtained in Lemma 4.4, we get that, for an arbitrary positive constant $c$ at most $1/(2\sqrt{\pi})$ and $D$ large enough,
\[
  \frac{K_{I_1}}{\kappa_d} \leq \exp \left( -D(D + \beta) \left( cD^{1/2} - 2 \log \left( \frac{D}{\pi} \right) \right) \right),
\]
which goes to zero. This concludes the proof.
Lemma 4.7. If $b$ is chosen as in (20), then $\frac{K_{11}}{\kappa_d} \to 0$ as $d \to \infty$.

Proof. We bound $F_{D+\beta-1} \leq 1$ so that

$$
1^b \leq \int_b^1 (1 - h^2)^{2D(D+\beta)-1} dh = \int_0^{1-b^2} \frac{s^{2D(D+\beta)-1}}{2\sqrt{1-s}} ds
$$

$$
\leq \frac{(1 - b^2)^{2D(D+\beta)}}{4bD(D + \beta)} = \frac{1}{4bD(D + \beta)} \left( \frac{x}{D} \right)^{2D(D+\beta)},
$$

where we used the fact that $1 - b^2 = x/D$. By Lemma 4.4 it follows that

$$
\frac{K_{11}}{\kappa_d} b \leq \frac{1}{4bD(D + \beta)},
$$

which tends to 0 as $D$ tends to infinity.

Proof of Corollary 3.2. First of all, note that from the definition of intrinsic volume we get that

$$
V_k(B^d) = \binom{d}{k} \frac{\kappa_d}{\kappa_{d-k}},
$$

Indeed, by plugging $K = B^d$ into (3), we get for every $t > 0$,

$$
\text{vol}_d(B^d) \sum_{k=0}^d \binom{d}{k} t^{d-k} = \text{vol}_d((1 + t)B^d) = \sum_{k=0}^d \kappa_{d-k} V_k(B^d) t^{d-k},
$$

which yields the required identity by comparing the coefficients of the two polynomials.

Moreover, Proposition 2.3 in [14] states that

$$
\mathbb{E} V_k(P_{n,d}^\beta) = \binom{d}{k} \frac{\kappa_d}{\kappa_{k\kappa_{d-k}}} \mathbb{E} \text{vol}_k(P_{n,k}^{\beta'})
$$

with $\beta' := \frac{d-k}{2} + \beta$. Together with the previous identity this implies that

$$
\frac{\mathbb{E} V_k(P_{n,d}^\beta)}{V_k(B^d)} = \frac{\mathbb{E} \text{vol}_d(P_{n,d}^{\beta'})}{\text{vol}_d(B^d)}
$$

with $d' := k$. We can thus apply Theorem 3.1 to the RHS with

$$
n = \left( \frac{d'}{2x + o(1)} \right)^{d'/2 + \beta'} = \left( \frac{k}{2x + o(1)} \right)^{d/2 + \beta},
$$

which proves the claim, since $d'$ also diverges by hypotheses.

Proof of Corollary 3.3. The expected number of vertices of $P_{n,d}^0$ is given by

$$
\mathbb{E} f_0(P_{n,d}^0) = n \mathbb{P}(X_n \text{ is a vertex of } P_{n,d}^0).
$$

Observe that the latter event is the complement of $\{X_n \in P_{n-1,d}^0\}$, whose probability is $\mathbb{E} \text{vol}_d(P_{n-1,d}^0)/\text{vol}_d(B^d)$ because $X_n$ is uniformly distributed, since $\beta = 0$. Collecting these observations provides the so-called Efron’s equality, see [7],

$$
\frac{\mathbb{E} f_0(P_{n,d}^0)}{n} = 1 - \frac{\mathbb{E} \text{vol}_d(P_{n-1,d}^0)}{\text{vol}_d(B^d)}.
$$

Combining this equation with the conclusion of Theorem 3.1 yields the proof.
