Abstract
Loop corrections to the gravitational potential are usually inferred from scattering amplitudes, which seems quite different from how the linearized Einstein equations are solved with a static, point mass to give the classical potential. In this study we show how the Schwinger–Keldysh effective field equations can be used to compute loop corrections to the potential in a way which parallels the classical treatment. We derive explicit results for the one-loop correction from the graviton self-energy induced by a massless, minimally coupled scalar.

1. Introduction

Everyone who has studied general relativity is familiar with solving the linearized Einstein equations to derive the first correction due to a point particle. One expands the full metric about flat space,

\[
d^2 x = [\eta_{\mu\nu} + h_{\mu\nu}(t, \vec{x})] \, dx^\mu \, dx^\nu = -c^2 \, dt^2 + d\vec{x} \cdot d\vec{x} + h_{\mu\nu}(t, \vec{x}) \, dx^\mu \, dx^\nu. \tag{1}
\]

Linearizing the full Einstein equation gives

\[
R^{\mu\nu} - \frac{1}{2} g^{\mu\nu} R = \frac{8 \pi G}{c^2} \times T^{\mu\nu} \implies \mathcal{D}^{\mu\nu\rho\sigma} h_{\rho\sigma}(t, \vec{x}) = \frac{8 \pi G}{c^2} \times M \delta_0^{\mu} \delta_0^{\nu} \delta^3(\vec{x}), \tag{2}
\]

where the flat space Lichnerowicz operator is

\[
\mathcal{D}^{\mu\nu\rho\sigma} = \frac{1}{2} [\eta^{\mu\rho} \eta^{\nu\sigma} \partial^2 - \partial^\mu \partial^\nu \eta^{\rho\sigma} - \eta^{\mu\nu} \partial^\rho \partial^\sigma - \eta^{\rho\nu} \eta^{\mu\sigma} \partial^2 + 2 \partial^{(\mu} \eta^{\nu)(\rho} \partial^{\sigma)}]. \tag{3}
\]

Up to a linearized gauge transformation, the solution is

\[
\begin{align*}
h_{00} &= \frac{2GM}{c^2 r}, & h_{0i} &= h_{i0} = 0, & h_{ij} &= \frac{2GM}{c^2 r} \, \vec{r}^i \vec{r}^j,
\end{align*}
\tag{4}
\]

where \( r \equiv |\vec{x}| \) and \( \vec{r}^i \equiv x^i / r \).
This is simple to understand and easy to extend to more complicated sources which can even change with time. Yet we are told that a completely different technique must be employed in order to include quantum corrections. Instead of solving the effective field equations, one computes the gravitational contribution to the amplitude for 2-particle scattering. Then the inverse scattering problem is used to reconstruct the potentials. For matter particles one only needs to correct the graviton propagator, which was done long ago for vectors [1, 2], spin-$\frac{1}{2}$ fermions [3] and scalars [4]. The general result for the long range Newtonian potential is [5–7]

$$h_{00} \rightarrow \frac{2GM}{c^2r} \left( 1 + \left[ N_{0,c} + \frac{9}{4} N_{0,m} + 3 N_1 + 12 N_1 \right] \frac{hG}{45 \pi c^3 r^2} + O(G^2) \right),$$

(5)

where $N_s$ indicates the number of particles of spin $s$ contributing to the graviton self-energy, with $N_{0,c}$ and $N_{0,m}$ denoting the number of conformally and minimally coupled scalars, respectively. Including gravitons is very much harder and has been the work of decades because one must also correct the vertices [1, 6, 8–11]. The generally accepted result seems to be [12]

$$h_{00} \rightarrow \frac{2GM}{c^2r} \left( 1 + \frac{41hG}{10\pi c^3 r^2} + O(G^2) \right).$$

(6)

There have also been results for gravitational quantum corrections to the potentials for charged [13] and spinning sources [14].

The scattering amplitude technique is certainly correct, although there have been many disputes about its application to graviton corrections [11]. What bewilders is the contrast between it and the classical procedure. Why must we do an asymptotic scattering experiment to infer the gravitational force in quantum field theory when we can observe orbits over finite times to get it classically? And what would we do for a dynamic source which was evolving? The notion of quantum-corrected, effective field equations is more than half a century old [15]; why is there not some way of solving them in analogy to the classical computation?

In fact there is such a technique, and we will employ it here to solve for the one-loop change in the gravitational potentials due to a massless, minimally coupled scalar field. The results for massless particles have long been known for flat space [5–7], but the method we describe can be used as well in de Sitter background, for which the absence of an $S$-matrix [16, 17] precludes the scattering amplitude technique. This paper will serve as a warm-up exercise for that more challenging computation, as well as an important correspondence limit.

Section 2 is devoted to explaining the general formalism. The actual computation is done in section 3. Our results are summarized and discussed in section 4.

2. Schwinger–Keldysh effective field equations

The graviton self-energy $-i^{\mu\nu} \Sigma^{\rho\sigma}(x; x')$ is the one-particle-irreducible (1PI) 2-point function for the graviton field $h_{\mu\nu}(t, \vec{x})$. It serves to quantum correct the linearized Einstein equation (2):

$$\mathcal{D}^{\mu\nu\rho\sigma} h_{\rho\sigma}(x) + \int d^4x' [^{\mu\nu} \Sigma^{\rho\sigma}](x; x') h_{\rho\sigma}(x') = \frac{8\pi G}{c^2} M \delta_0^x \delta_0^{x'} \delta^3(\vec{x}).$$

(7)

However, this equation suffers from two embarrassments:

- it is not causal because the in-out self-energy is nonzero for points $x'^\mu$ which are spacelike separated from $x^\mu$, or lie to its future; and
- it does not produce real potentials $h_{\mu\nu}$ because the in-out self-energy has an imaginary part.
One can get the right result for a static potential by simply ignoring the imaginary part [5, 7, 9], but circumventing the limitations of the in-out formalism becomes more and more difficult as time-dependent sources and higher order corrections are included, and these techniques break down entirely for the case of cosmology in which there may not even be asymptotic vacua. It is not that the in-out self-energy is somehow ‘wrong’. In fact, it is exactly the right thing to correct the Feynman propagator for asymptotic scattering computations in flat space. The point is rather that equation (7) does not provide the generalization we seek of the classical field equation (2).

The better technique is known as the Schwinger-Keldysh formalism [18]. It provides a way of computing true expectation values that is almost as simple as the Feynman diagrams which produce in-out matrix elements. The Schwinger-Keldysh rules are best stated in the context of a scalar field \( \phi(x) \) whose Lagrangian (the space integral of its Lagrangian density) at time \( t \) is \( L[\phi(t)] \). Suppose we are given a Heisenberg state \( |\Psi\rangle \) whose wave functional in terms of the operator eigenkets at time \( t_0 \) is \( \Psi[\phi(t_0)] \), and we wish to take the expectation value, in the presence of this state, of a product of two functionals of the field operator: \( A[\phi] \), which is anti-time-ordered, and \( B[\phi] \), which is time-ordered. The Schwinger-Keldysh functional integral for this is [19]

\[
\langle \Psi | A[\phi] B[\phi] | \Psi \rangle = \left[ [\delta \phi_+] [\delta \phi_-] \delta[\phi_-(t_1) - \phi_+(t_1)] \right]
\times A[\phi_-] B[\phi_+] \Psi^* \left[ \phi_0(t_0) \right] e^{\int_{t_0}^{t_1} dt \left[ L[\phi(t)] - L[\phi_+(t)] \right]} \Psi[\phi_+(t_0)].
\]

The time \( t_1 \) > \( t_0 \) is arbitrary as long as it is later than the latest operator which is contained in either \( A[\phi] \) or \( B[\phi] \).

The Schwinger-Keldysh rules can be read off from its functional representation (8). Because the same field operator is represented by two different dummy functional variables, \( \phi_\pm(x) \), the endpoints of lines carry a + polarity. External lines associated with the anti-time-ordered operator \( A[\phi] \) have the + polarity, whereas those associated with the time-ordered operator \( B[\phi] \) have the - polarity. Interaction vertices are either all +, or all -. Vertices with + polarity are the same as in the usual Feynman rules, whereas vertices with the - polarity have an additional minus sign. If the state \( |\Psi\rangle \) is something other than free vacuum then it contributes additional interaction vertices on the initial value surface [20].

Propagators can be +, +, -- or --. All four polarity variations can be read off from the fundamental relation (8) when the free Lagrangian is substituted for the full one. It is useful to denote canonical expectation values in the free theory with a subscript 0. With this convention we see that the - propagator is just the ordinary Feynman propagator:

\[
i\Delta_{++}(x; x') = \langle \Omega | T(\phi(x)\phi(x')) | \Omega \rangle_0 = i\Delta(x; x'),
\]

where \( T \) stands for time-ordering and \( \overline{T} \) denotes anti-time-ordering. The other polarity variations are simple to read off and to relate to the Feynman propagator:

\[
i\Delta_{+-}(x; x') = \langle \Omega | \phi(x)\phi(x') | \Omega \rangle_0 = \theta(t - t')i\Delta(x; x') + \theta(t' - t)[i\Delta(x; x')]^*,
\]

\[
i\Delta_{-+}(x; x') = \langle \Omega | \phi(x')\phi(x) | \Omega \rangle_0 = \theta(t - t')i\Delta(x; x')^* + \theta(t' - t)i\Delta(x; x'),
\]

\[
i\Delta_{--}(x; x') = \langle \Omega | \overline{T}(\phi(x)\phi(x')) | \Omega \rangle_0 = [i\Delta(x; x')]^*.
\]

Therefore, we can get the four propagators of the Schwinger-Keldysh formalism from the Feynman propagator once that is known.

Because external lines can be either + or -- in the Schwinger-Keldysh formalism, every 1PI N-point function of the in-out formalism gives rise to \( 2^N \) 1PI N-point functions in the
Schwinger–Keldysh formalism. For every classical field \( \phi(x) \) of an in-out effective action, the corresponding Schwinger–Keldysh effective action must depend upon two fields—call them \( \phi_+(x) \) and \( \phi_-(x) \)—in order to access the appropriate 1PI function [21]. For the scalar paradigm we have been considering, this effective action takes the form

\[
\Gamma[\phi_+, \phi_-] = S[\phi_+] - S[\phi_-] - \frac{1}{2} \int d^4x \int d^4x' \times \left\{ \phi_+(x) M^{++}_{++}(x; x') \phi_+(x') + \phi_+(x) M^{++}_{+-}(x; x') \phi_-(x') + \phi_-(x) M^{++}_{-+}(x; x') \phi_+(x') + \phi_-(x) M^{++}_{--}(x; x') \phi_-(x') \right\} + O(\phi^3), \tag{13}
\]

where \( S \) is the classical action. The effective field equations are obtained by varying with respect to \( \phi_+ \) and then setting both fields equal [21]:

\[
\frac{\delta \Gamma[\phi_+, \phi_-]}{\delta \phi_+(x)} \bigg|_{\phi_=\phi} = [\beta^2 - m^2] \phi(x) - \int d^4x' \left[ M^{++}_{++}(x; x') + M^{++}_{--}(x; x') \right] \phi(x') + O(\phi^2). \tag{14}
\]

The two 1PI 2-point functions we would need to quantum correct the linearized scalar field equation are \( M^{++}_{++}(x; x') \) and \( M^{++}_{--}(x; x') \). Their sum in (14) gives effective field equations which are causal in the sense that the two 1PI functions cancel unless \( x' \) lies on or within the past light-cone of \( x \). Their sum is also real, which neither 1PI function is separately.

As mentioned before, the point of the present paper is to lay the groundwork for a computation of the one-loop correction to the force of gravity on de Sitter background. The graviton contribution to the self-energy was computed some years ago [22] but has never been used in the effective field equations. A computation of the scalar contribution is underway.

Although the current computation will be the first to explore corrections to a force law, the linearized effective field equations have been studied on de Sitter background for many simpler models. In scalar quantum electrodynamics the one-loop vacuum polarization was computed and used to correct for the propagation of dynamical photons [23, 24], but not yet for the Coulomb force. The one-loop scalar self-mass-squared has also been used to correct for the propagation of charged, massless, minimally coupled scalars [25]. Both the fermion [26] and scalar [27] 1PI 2-point functions of Yukawa theory have been computed and used to correct the mode functions. The one- and two-loop scalar self-mass-squared of \( \lambda \phi^4 \) theory has been computed and used to correct for the propagation of massless, minimally coupled scalars [28]. In Einstein + Dirac the one-loop fermion self-energy has been computed and used to correct the fermion mode function [29]. And the same thing has been done for scalars in scalar + Einstein [30].

3. Solving for the potentials

This section is the heart of the paper. We begin by expressing the linearized effective field equations in a form which is both manifestly real and causal. We then explain how these equations can be solved perturbatively. The hardest step is integrating the one-loop self-energy against the tree order solution. The section closes by working out the two one-loop potentials.

3.1. Achieving a manifestly real and causal form

The basis for our work is a position space result for the one-loop contribution to the 1PI graviton 2-point function from a loop of massless, minimally coupled scalars, using dimensional regularization and a minimal choice for the higher derivative counterterms [19]. (Previous
are complex conjugates of one another for the linearized, one-loop effective field equations is the Lichnerowicz operator parameter of quantum gravity and the four Schwinger–Keldysh length functions are 

\[ \mu = \frac{1}{16\pi}\frac{\bar{h}G/c^3}{(\kappa^2 t - \kappa^2 t')} \]  

where \( \kappa^2 = 16\pi\hbar G/c^3 \) is the loop-counting parameter of quantum gravity and the four Schwinger–Keldysh length functions are 

\[ \Delta x^\pm_\pm(x; x') = \ln \left( \frac{\mu^2 \Delta x^2_\pm}{\Delta x^2_\pm} \right) \]  

The four bi-scalars are 

\[ \Sigma_{\pm\pm}(x; x') = (\pm)(\pm) \frac{24925\pi^4}{40960\pi^4} \left[ \ln \left( \frac{\mu^2 \Delta x^2_\pm}{\Delta x^2_\pm} \right) - 2 \ln \left( \mu^2 \Delta x^2_\pm \right) \right] \]  

where \( \mu^2 \) is the usual scale of dimensional regularization, \( \kappa^2 = 16\pi\hbar G/c^3 \) is the loop-counting parameter of quantum gravity and the four Schwinger–Keldysh length functions are 

\[ \Delta x^2_\pm(x; x') = \ln \left( \frac{\mu^2 \Delta x^2_\pm}{\Delta x^2_\pm} \right) \]  

Now define the position and temporal separations, and the associated invariant length-squared: 

\[ \Delta r = \| \vec{x} - \vec{x}' \|, \quad \Delta t = t - t', \quad \Delta x^2 = \Delta r^2 - c^2 \Delta t^2 \]  

The \( \pm \) and \( \pm \) logarithms can be expanded in terms of their real and imaginary parts: 

\[ \ln(\mu^2 \Delta x^2_\pm) = \ln(\mu^2 \Delta x^2_\pm) + i\pi \theta(-\Delta x^2), \]  

\[ \ln(\mu^2 \Delta x^2_\pm) = \ln(\mu^2 \Delta x^2_\pm) - i\pi \sgn(\Delta t)\theta(-\Delta x^2). \]  

The \( \pm \) and \( \pm \) logarithms agree for spacelike separation (\( \Delta x^2 > 0 \)) and for \( t' > t \), whereas they are complex conjugates of one another for \( x^\mu = (ct, \vec{x}) \) in the past-light cone of \( x^\mu = (ct, \vec{x}) \). Hence, the sum of \( \Sigma_{++}(x; x') \) and \( \Sigma_{+-}(x; x') \) is both causal and real:

\[ \Sigma_{++}(x; x') + \Sigma_{+-}(x; x') = -\frac{\kappa^2\delta^4}{10240\pi^4} \theta(c\Delta t - \Delta r) \left[ \ln(-\mu^2 \Delta x^2) - 1 \right]. \]  

Let us assume that the state is released in free vacuum at time \( t = 0 \). Our final result for the linearized, one-loop effective field equations is 

\[ \mathcal{D}^{\mu\nu\rho\sigma} h_{\rho\sigma}(t, \vec{x}) = \frac{\kappa^2\delta^4}{10240\pi^4} \int_0^t dt' \int d^3x' \theta(c\Delta t - \Delta r) \times \left[ \ln(-\mu^2 \Delta x^2) - 1 \right] h_{\rho\sigma}(t', \vec{x}') = \frac{8\pi GM}{c^2} \delta^4_{\kappa^2} \delta^4(\vec{x}). \]  

Recall that \( \kappa^2 = 16\pi\hbar G/c^3 \) is the loop-counting parameter of quantum gravity, the Lichnerowicz operator \( \mathcal{D}^{\mu\nu\rho\sigma} \) was given in (3) and the fourth-order differential operator \( D^{\mu\nu\rho\sigma} \) was given in (16).
3.2. Solving the equation perturbatively

There is no point in trying to solve equation (27) exactly because it only includes the one-loop graviton self-energy. A better approach is to seek a perturbative solution in powers of the loop-counting parameter $\kappa^2$:

$$h_{\mu\nu}(t, \vec{x}) = \sum_{\ell=0}^{\infty} \kappa^{2\ell} h^{(\ell)}_{\mu\nu}(t, \vec{x}).$$

(28)

Of course, the $\ell = 0$ term obeys the linearized Einstein equation whose solution in Schwarzschild coordinates is

$$D^{\mu\rho\sigma} h^{(0)}_{\rho\sigma}(t, \vec{x}) = \frac{8\pi GM}{c^2} \delta_0^{\mu} \delta_0^{\rho} \delta^3(\vec{x}) \implies h^{(0)}_{00} = \frac{2GM}{c^2r}, \quad h^{(0)}_{ij} = \frac{2GM}{c^2r} \hat{r}_i \hat{r}_j.$$  

(29)

The one-loop correction $h^{(1)}_{\mu\nu}$ obeys the equation

$$D^{\mu\rho\sigma} h^{(1)}_{\rho\sigma}(t, \vec{x}) = \frac{D^{\mu\rho\sigma} \partial^4}{10240\pi^3} \int_0^t dt' \int d^3x' \theta(\Delta t - \Delta r)[\ln(-\mu^2 \Delta x^2) - 1] h^{(0)}_{\rho\sigma}(t', \vec{x}').$$  

(30)

Finding the two-loop correction $h^{(2)}_{\mu\nu}$ would require the two-loop self-energy, which we do not have, so $h^{(1)}_{\mu\nu}$ is as high as we can go.

3.3. The one-loop source term

In this subsection we evaluate the right-hand side of equation (30), which sources the one-loop correction $h^{(1)}_{\mu\nu}(t, \vec{x})$. This is done in three steps: we first perform the integral, then act the $\partial^4$ and finally act the $D^{\mu\rho\sigma}$.

From the form of the tree order potentials (29), it is apparent that we need two integrals. The first comes from $h^{(0)}_{00}$:

$$\int_0^t dt' \int d^3x' \theta(\Delta t - \Delta r)[\ln(-\mu^2 \Delta x^2) - 1] \times \frac{1}{||\vec{x}'||} \equiv F(t, r).$$  

(31)

The second integral is derived from the other nonzero potential $h^{(0)}_{ij}$. Its trace part is obviously the same as $F(t, r)$, and we shall call its traceless part $G(t, r)$.

$$\int_0^t dt' \int d^3x' \theta(\Delta t - \Delta r)[\ln(-\mu^2 \Delta x^2) - 1] \times \frac{\hat{r}_i \hat{r}_j}{||\vec{x}'||}$$

$$= \frac{1}{2}[\delta^{ij} - \hat{r}^i \hat{r}^j]F(t, r) - \frac{1}{2}[\delta^{ij} - 3\hat{r}^i \hat{r}^j]G(t, r),$$  

(32)

$$= \frac{1}{3} \delta^{ij}F(t, r) + \frac{1}{2}[3\hat{r}^i \hat{r}^j - \delta^{ij}][G(t, r) - \frac{1}{3} F(t, r)].$$  

(33)

The integrals are tedious but straightforward and give the following results for $F(t, r)$ and the combination $G(t, r) - \frac{1}{3} F(t, r)$:

$$F(t, r) = \frac{4\pi}{r} \left\{ \frac{r^4}{6} \ln(2\mu r) - \frac{25}{72} r^4 + \frac{11}{18} r^3 ct - \frac{11}{18} r^3 c^2 t + \left[ \frac{1}{12} (ct + r)^4 - \frac{r}{6} (r + ct) \right] \ln[\mu(ct + r)] - \left[ \frac{1}{12} (ct - r)^4 + \frac{r}{6} (ct - r)^3 \right] \ln[\mu(ct - r)] \right\},$$  

(34)
\[ G(t, r) - \frac{F(t, r)}{3} = \frac{4\pi}{r} \left\{ -\frac{r^4}{9} \ln(2\mu r) + \frac{23}{108} r^4 - \frac{199}{675} r^3 ct - \frac{13}{135} r^3 ct^3 + \frac{2c^5 t^5}{45r} \right. \]
\[ + \left[ -\frac{(ct + r)^6}{45r^2} + \frac{2}{15} \frac{(ct + r)^5}{r} - \frac{5}{18} (ct + r)^4 + \frac{2}{9} (ct + r)^3 \right] \ln[\mu(ct + r)] \]
\[ + \left[ \frac{(ct - r)^6}{45r^2} + \frac{2}{15} \frac{(ct - r)^5}{r} + \frac{5}{18} (ct - r)^4 + \frac{2}{9} (ct - r)^3 \right] \ln[\mu(ct - r)] \right\}. \tag{35} \]

The next step is acting the two d’Alembertians. This purges all the time-dependent terms,
\[ \partial^4 F(t, r) = \frac{4\pi}{r} \times 4 \ln(2\mu r). \tag{36} \]

\[ \partial^4 \left\{ \frac{1}{3} \delta^{ij} F(t, r) + \frac{1}{2} [\hat{r}^i \hat{r}^j - \delta^{ij}] \left[ G(t, r) - \frac{1}{3} F(t, r) \right] \right\} \]
\[ = \frac{4\pi}{r} \left\{ \frac{4}{3} \delta^{ij} \ln(2\mu r) + [\hat{r}^i \hat{r}^j - \delta^{ij}] \left[ \frac{4}{3} \ln(2\mu r) - \frac{2}{r} \right] \right\}. \tag{37} \]

At this stage the linearized, one-loop effective field equations (27) take the form
\[ D^{\mu\nu\rho\sigma} h^{(1)}(\vec{x}) = \frac{GM}{128\pi^2 c^2} D^{\mu\nu\rho\sigma} f^{(1)}(\vec{x}), \tag{38} \]
where the nonzero components of the tensor \( f^{(1)}(\vec{x}) \) are
\[ f_{00}(\vec{x}) = \frac{4}{r} \ln(2\mu r), \tag{39} \]
\[ f_{ij}(\vec{x}) = \delta^{ij} \times \frac{4}{3} \ln(2\mu r) + [\hat{r}^i \hat{r}^j - \delta^{ij}] \left[ \frac{4}{3} \ln(2\mu r) - \frac{2}{r} \right]. \tag{40} \]

It remains only to act the operator \( D^{\mu\nu\rho\sigma} \) on \( f^{(1)}(\vec{x}) \). The first two derivatives give
\[ \partial^2 f_{00} = -\frac{4}{r^3}, \quad \partial^2 f_{ij} = \hat{r}^i \left[ \frac{4}{3} \ln(2\mu r) - 4 \right] \frac{1}{r^2}, \tag{41} \]
\[ \partial^2 f_{00} = -4 \frac{18}{r^3}, \quad \partial^2 f_{ij} = \hat{r}^i \left[ \frac{12}{r^3} \ln(2\mu r) - 12 \right] - \hat{r}^i \left[ \frac{24}{r^3} \ln(2\mu r) - 32 \right], \tag{42} \]
\[ \partial_i \partial_j f_{00} = \partial_i \partial_j f_{ij}, \quad \partial_i \partial_k f_{jk} = \delta^{ij} \left[ \frac{12}{r^3} \ln(2\mu r) - 16 \right] - \hat{r}^j \left[ \frac{24}{r^3} \ln(2\mu r) - 32 \right]. \tag{43} \]

The source term can then be expressed in terms of two more derivatives of the quantities \( g_{\mu\nu}(\vec{x}) \equiv \nabla^2 f_{\mu\nu}(\vec{x}) \) and \( g(\vec{x}) \equiv \partial_i \partial_j f_{ij}(\vec{x}) \):
\[ D^{\mu\nu\rho\sigma} h^{(1)}(\vec{x}) = \frac{GM}{128\pi^2 c^2} \left\{ -\eta^{\alpha\nu} \nabla^2 g + \frac{4}{3} \partial^\mu \partial^\nu g + \frac{1}{3} \nabla^2 g^{\mu\nu} - \frac{2}{3} \partial_\rho \delta^{(\mu} g^{\nu)\rho} \right\}. \tag{44} \]

The final reduction employs the identities
\[ \nabla^2 g = \frac{24}{r^3}, \quad \partial_i \partial_j g = -\frac{12}{r^3} \delta^{ij} + \frac{60}{r^3} \hat{r}^i \hat{r}^j, \tag{45} \]
\[ \nabla^2 g_{00} = -\frac{24}{r^5}, \quad \nabla^2 g_{ij} = -\frac{48}{r^5} \delta^{ij} + \frac{120}{r^3} \hat{r}^i \hat{r}^j, \]  
(46)

\[ \partial_k g_{jk} = -\frac{12}{r^4} \hat{r}^j, \quad \partial_i \partial_k g_{jk} = -\frac{12}{r^5} \delta^{ij} + \frac{60}{r^3} \hat{r}^i \hat{r}^j. \]  
(47)

The nontrivial components of the effective field equations are

\[ \mathcal{D}^{00\sigma} h_{\rho\sigma}^{(1)}(t, \vec{x}) = \frac{GM}{80\pi^2 c^2} \times \frac{1}{r^5}, \]  
(48)

\[ \mathcal{D}^{ij\sigma} h_{\rho\sigma}^{(1)}(t, \vec{x}) = \frac{GM}{80\pi^2 c^2} \times \left\{ -\frac{3\delta^{ij}}{r^5} + \frac{5\hat{r}^i \hat{r}^j}{r^5} \right\}. \]  
(49)

3.4. The one-loop potentials

We wish to express the one-loop potentials in Schwarzschild coordinates, so their nonzero components take the form

\[ h_{00}^{(1)}(\vec{x}) = a(r), \quad h_{ij}^{(1)}(\vec{x}) = \hat{r}^i \hat{r}^j b(r). \]  
(50)

Acting the Lichnerowitz operator (3) on these gives

\[ \mathcal{D}^{00\sigma} h_{\rho\sigma}^{(1)} = b' \frac{b}{r} \hat{r}^2, \]  
(51)

\[ \mathcal{D}^{ij\sigma} h_{\rho\sigma}^{(1)} = \delta^{ij} \left[ \frac{a''}{2} - \frac{a'}{2r} - \frac{b'}{2r} - \frac{b}{r^2} \right] + \hat{r}^i \hat{r}^j \left[ \frac{a''}{2} - \frac{a'}{2r} + \frac{b'}{2r} - \frac{b}{r^2} \right]. \]  
(52)

Comparing (51) with (48) implies

\[ b(r) = \frac{GM}{160\pi^2 c^2} \times -\frac{1}{r^3}. \]  
(53)

Substituting this into (52) and comparing with (49) implies

\[ a(r) = \frac{GM}{160\pi^2 c^2} \times \frac{1}{r^3}. \]  
(54)

Combining the classical and quantum corrections gives the following total results for the potentials:

\[ h_{00}(\vec{x}) = \frac{2GM}{c^2 r} \left\{ 1 + \frac{hG}{20\pi c^3 r^2} + O\left( \frac{\kappa^4}{r^4} \right) \right\}, \]  
(55)

\[ h_{ij}(\vec{x}) = \frac{2GM}{c^2 r} \left\{ 1 - \frac{hG}{20\pi c^3 r^2} + O\left( \frac{\kappa^4}{r^4} \right) \right\} \hat{r}^i \hat{r}^j. \]  
(56)

Expression (55) agrees with equation (3.9) of Hamber and Liu [6], and also with equation (32) of [33]. When transformed to de Donder gauge, our results (55)–(56) give the same trace obtained in equation (59) by Dalvit and Mazzitelli [34].
4. Discussion

We have used the Schwinger–Keldysh formalism to derive manifestly causal and real, linearized effective field equations (27) for $h_{\mu\nu}(t, \vec{x})$ which include the one-loop quantum effects of a massless, minimally coupled scalar. We used this equation to solve for the quantum corrections to the potentials (55)–(56) associated with a stationary point mass. Similar results have been obtained for conformally coupled scalars, fermions and vectors [5, 7]. The massless, minimally coupled scalar result is also known [6], but the real power of our analysis is the field equation (27), which could be used even for a time-dependent source. Our results (55)–(56) will also serve as an important correspondence limit for an on-going computation of the quantum-corrected potentials on a locally de Sitter background.

An important caveat to this analysis is that the full linearized effective field equations must include quantum corrections to the stress energy of the source as well as corrections to the graviton kinetic operator. For our problem, the scalar makes no contribution to the stress energy of the point mass which was our source. However, if we had considered quantum gravitons, it would have been necessary to correct the stress tensor, and some account would also have to be taken of the fact that the potentials would be measured by coupling through a corrected vertex. These complications are among the reasons why it required so much more work to derive reliable results for gravitons [1, 6, 8–12].

Finally, it is worth noting that the massless, minimally coupled scalar stands in isolation to its conformally coupled cousin. The self-energies of both scalars take the same form:

Minimally coupled $\implies \left[ \mu^{\nu} \Sigma^{\rho\sigma}_{\pm} \right] = (\pm) (\pm) \frac{i k^2 D^{\mu\nu\rho\sigma} \partial^2}{5120 \pi^4} \left[ \ln \left( \frac{\mu^2 \Delta x^2_{\pm}}{\Delta x^2_{\pm}} \right) \right]$, (57)

Conformally coupled $\implies \left[ \mu^{\nu} \tilde{\Sigma}^{\rho\sigma}_{\pm} \right] = (\pm) (\pm) \frac{i k^2 \tilde{D}^{\mu\nu\rho\sigma} \partial^2}{5120 \pi^4} \left[ \ln \left( \frac{\mu^2 \Delta x^2_{\pm}}{\Delta x^2_{\pm}} \right) \right]$. (58)

However, the fourth-order operator $D^{\mu\nu\rho\sigma}$ has a nonzero trace, whereas $\tilde{D}^{\mu\nu\rho\sigma}$ is traceless:

$D^{\mu\nu\rho\sigma} = \Pi^{\mu\nu} \Pi^{\rho\sigma} + \frac{1}{2} \Pi^{(\rho} \Pi^{\nu)\sigma}$, (59)

$\tilde{D}^{\mu\nu\rho\sigma} = \frac{1}{9} \Pi^{\mu\nu} \Pi^{\rho\sigma} + \frac{1}{3} \Pi^{(\rho} \Pi^{\nu\sigma)}$, (60)

where $\Pi^{\mu\nu} \equiv \eta^{\mu\nu} \partial^2 - \partial^{[\mu} \partial^{\nu]}$. The graviton self-energy from a massless, 2-component fermion is three times that of the massless, conformally coupled scalar (58), and the result for a massless vector is 12 times (58), so the massless, minimally coupled scalar is the exceptional case. This distinction becomes even greater in de Sitter background on which massless, minimally coupled scalars experience explosive particle production, whereas the various massless, conformally invariant particles do not. (For a simple discussion, see section 3 of [35].)
