Abstract
A bivariate random vector can exhibit either asymptotic independence or dependence between the largest values of its components. When used as a statistical model for risk assessment in fields such as finance, insurance or meteorology, it is crucial to understand which of the two asymptotic regimes occurs. Motivated by their ubiquity and flexibility, we consider the extremal dependence properties of vectors with a random scale construction \((X_1, X_2) = R(W_1, W_2)\), with non-degenerate \(R > 0\) independent of \((W_1, W_2)\). Focusing on the presence and strength of asymptotic tail dependence, as expressed through commonly-used summary parameters, broad factors that affect the results are: the heaviness of the tails of \(R\) and \((W_1, W_2)\), the shape of the support of \((W_1, W_2)\), and dependence between \((W_1, W_2)\). When \(R\) is distinctly lighter tailed than \((W_1, W_2)\), the extremal dependence of \((X_1, X_2)\) is typically the same as that of \((W_1, W_2)\), whereas similar or heavier tails for \(R\) compared to \((W_1, W_2)\) typically result in increased extremal dependence. Similar tail heavinesses represent the most interesting and technical cases, and we find both asymptotic independence and dependence of \((X_1, X_2)\) possible in such cases when \((W_1, W_2)\) exhibit asymptotic independence. The bivariate case often directly extends to higher-dimensional vectors and spatial processes, where the dependence is mainly analyzed in terms of summaries of bivariate sub-vectors. The results unify and extend many existing examples, and we use them to propose new models that encompass both dependence classes.

1 Introduction

A rich variety of bivariate dependence models have a pseudo-polar representation

\[(X_1, X_2) = R(W_1, W_2), \quad R > 0, \text{ independent of } (W_1, W_2) \in \mathcal{W} \subseteq \mathbb{R}^2, \tag{1}\]

where we term \(R\) the radial variable, assumed to have a non-degenerate distribution, and \((W_1, W_2)\) the angular variables. Indeed, many well-known copula families, including the elliptical, Archimedean, Liouville, and multivariate Pareto families have such a representation. In this work, our focus is on the upper tail dependence of such constructions. In particular, we examine whether a given \((X_1, X_2)\) displays asymptotic dependence or asymptotic independence, and the strength of dependence within these classes. Our results are particularly useful for constructing new models with properties that reflect the challenges of real data in, for instance, finance, meteorology and hydrology. Specifically, it is often ambiguous whether data should be modeled using an asymptotically dependent or asymptotically independent distribution, and most families of distributions only exhibit one type of dependence. A vector \((X_1, X_2)\) with \(X_j \sim F_{X_j}\) is said to display asymptotic dependence if the limit

\[\chi_X = \lim_{q \to 1} \mathbb{P}\left\{X_1 \geq F_{X_1}^{-1}(q), X_2 \geq F_{X_2}^{-1}(q)\right\} / (1 - q) \tag{2}\]

exists and is positive; a limit of zero defines asymptotic independence. In Eq. 2 and throughout, \(F_{X_j}^{-1}\) denotes the (generalized) inverse of the distribution function \(F_{X_j}\). The parameter \(\chi_X\) is termed the (upper) tail dependence coefficient, and the value of \(\chi_X \in (0, 1]\) summarizes the strength of the dependence within the class of asymptotically dependent variables. Under asymptotic independence, a more useful summary is the rate at which the convergence to zero in Eq. 2 occurs, and a widely satisfied assumption (Ledford and Tawn 1997) is

\[\mathbb{P}\{X_1 \geq F_{X_1}^{-1}(q), X_2 \geq F_{X_2}^{-1}(q)\} = \ell(1 - q) (1 - q)^{1/\eta_X}, \quad \eta_X \in [0, 1], \tag{3}\]

where \(\ell : [0, 1] \to \mathbb{R}_+\) is slowly varying at zero, i.e., \(\lim_{s \to 0} \ell(sx)/\ell(s) = 1, x > 0\). The parameter \(\eta_X\) is termed the residual tail dependence coefficient; positive and negative extremal association are indicated respectively by \(\eta_X \in (1/2, 1]\) and \(\eta_X \in [0, 1/2]\), whilst asymptotically dependent variables have \(\eta_X = 1\) and \(\chi_X = \lim_{q \to 1} \ell(1 - q)\). A value of \(\eta_X = 0\) means that the left-hand side of Eq. 3 decays faster than any power of \(1 - q\), whilst if the left-hand side is exactly zero for some \(q < 1\), we say that \(\eta_X\) is not defined.

Our particular interest in the extremal dependence of constructions of the form (1) stems not from their novelty, but from their ubiquity and flexibility. As mentioned, Eq. 1 already encompasses many well-known families, and moreover these families display different types of extremal dependence, which may be determined by the distribution of \(R\), the distribution of \((W_1, W_2)\), or its support \(\mathcal{W}\). There is a large body of literature that treats either individual constructions of the form (1), or a particular subset of these constructions where \(R\) or \((W_1, W_2)\) have certain specified properties; this literature will be reviewed in Section 4. Our aim is to bring this scattered treatment together and to more systematically characterize how the extremal dependence
of \((X_1, X_2)\) is determined by the properties of \(R\) and \((W_1, W_2)\). By understanding which facets of the construction lead to different dependence properties, we are able to determine dependence models that can capture both types of extremal dependence within a single parametric family; the recent proposals in Wadsworth et al. (2017), Huser et al. (2017) and Huser and Wadsworth (2019) are specific examples of this.

A broad split in representations of type (1) is the dimension of \(\mathcal{W}\), the support of \((W_1, W_2)\). The most common case in the literature is that \(W\) is a one-dimensional subset of \(\mathbb{R}^2\), such as the unit sphere defined by some norm or other homogeneous function. Examples include the Mahalanobis norm (elliptical distributions), \(L_1\) norm (Archimedean and Liouville distributions), or \(L_\infty\) norm (multivariate Pareto distributions). On top of the support \(\mathcal{W}\), to obtain distributions within a particular family, \(R\) or \((W_1, W_2)\) may be specified to have a certain distribution. Where \(W\) is two-dimensional, it may sometimes be reduced to the one-dimensional case by redefining \(R\), such as in the Gaussian scale mixtures of Huser et al. (2017); other times, such as for the scale mixtures of log-Gaussian variables in Krupskii et al. (2018), or the model presented in Huser and Wadsworth (2019), this cannot be done. Where \(W\) is two-dimensional, the possible constructions stemming from Eq. 1 form an especially large class, since \((W_1, W_2)\) can itself have any copula. In this case, we focus on how the multiplication by \(R\) changes the extremal dependence of \((W_1, W_2)\), summarized by the coefficients \((\chi_W, \eta_W)\), to obtain the extremal dependence of the modified vector \((X_1, X_2)\) in terms of its coefficients \((\chi_X, \eta_X)\). The marginal distributions of \((W_1, W_2)\) and \(R\) will play a crucial role, since, intuitively, the heavier the tail of \(R\) the more additional dependence is introduced in the vector \((X_1, X_2)\).

As we are focused on the upper tail of \((X_1, X_2)\), we henceforth assume \((W_1, W_2)\in \mathbb{R}_+^2\); by the invariance of copulas to monotonic marginal transformations, this also covers random location constructions of the form \((Y_1, Y_2) = S + (V_1, V_2)\), \(S\in \mathbb{R}\), \((V_1, V_2)\in \mathbb{V} \subseteq \mathbb{R}^2\). For simplicity of presentation, we will often make the restriction that \(W_1\) and \(W_2\) have the same distribution, with comments on relaxations of this assumption given in Section 6. Furthermore, whilst our focus on the bivariate case permits simpler notation, many of the results are directly applicable to the bivariate margins of multivariate and spatial models, whose extremal dependence is typically analyzed in terms of the coefficients (2) and (3). Examples are given in Section 4, with further comment on higher dimensions in Section 6.

There is no widely recognized standard for ordering univariate tail decay rates from the slowest to the fastest, although a broad characterization is given by the three domains of attraction of the maximum. We say that the random variable \(R\) is in the max-domain of attraction (MDA) of a generalized extreme value distribution if there exists a function \(b(t) > 0\) such that as \(t \to r^* = \sup\{r : P(R \leq r) < 1\}\),

\[
P(R \geq t + r/b(t))/P(R \geq t) \to (1 + \xi r)^{-1/\xi}_+, \quad r \geq 0,
\]

for some \(\xi \in \mathbb{R}\), where \(a_+ = \max(a, 0)\). The cases \(\xi > 0, \xi = 0, \xi < 0\) define respectively the Fréchet, Gumbel and negative Weibull domains of attraction; the tail heaviness of \(R\) increases with \(\xi\). However, the Gumbel limit in particular attracts distributions with highly diverse tail behavior such as finite upper bounds or heavy tails. Overall, this classification is therefore too coarse for our requirements, and it
excludes important classes such as superheavy-tailed distributions defined through the property of heavy-tailed log-transformed random variables. In addition to the maximum domains of attraction, we will utilize various commonly used tail classes, which are defined in Section 1.1.

We begin in Section 2 by presenting results concerning the tail dependence of construction (1) according to the tail behavior of $R$ and the shape of $W$, in the case where it is a one-dimensional support defined through a norm. We then characterize various cases where $W$ is two-dimensional, according to the behavior of both $R$ and $(W_1, W_2)$, in Section 3. Section 4 is devoted to literature review and framing a large number of existing examples in terms of our general results, whilst Section 5 illustrates the properties of some new examples inspired by the developments in the manuscript. In Section 6 we comment on generalizations and conclude. Proofs are presented in Section 7.

1.1 Terminology and notation

For a random variable $Q$, we define its survival function $\bar{F}_Q(q) = P(Q \geq q)$, and distribution function $F_Q(q) = 1 - \bar{F}_Q(q)$. If $Q$ represents a bivariate random vector $Q = (Q_1, Q_2)$, we denote the minimum of its margins by $Q \wedge = Q_1 \wedge Q_2$.

Vectors are assumed to be column vectors. For two functions $f$ and $g$ with $g(x) \neq 0$ for values $x$ above some threshold value $x_0$, we write $f \sim g$ if $f(x)/g(x) \to 1$, where the limit is considered for $x \to \infty$ if not stated otherwise. Similarly, we write $f(x) = o(g(x))$ to indicate that $f(x)/g(x) \to 0$. The convolution of $X \sim F_X$ and $Y \sim F_Y$ is denoted $F_X \ast F_Y = F_{X+Y}$.

We recall definitions of upper tail behavior classes for a random variable $X$ with distribution $F$. Key tail parameters for these classes may be given as subscript, such as in $ET_\alpha$ to refer to exponential-tailed distributions with rate $\alpha$, but we may omit the subscript if the specific value of the parameter is not of interest.

**Definition 1** (Light-, heavy- and superheavy-tailed distributions) The distribution $F$ is heavy-tailed if $\exp(\lambda x)\bar{F}(x) \to \infty$ as $x \to \infty$, for any $\lambda > 0$. Further, $F$ is superheavy-tailed if $F(\exp(\cdot))$ is heavy-tailed. If $F$ is not heavy-tailed, it is light-tailed.

**Definition 2** (Regularly varying functions and distributions (RV$_0^\alpha$ and RV$_\infty^\alpha$)) A measurable function $g$ is regularly varying at infinity or at zero with index $\alpha \in \mathbb{R}$ if $g(tx)/g(t) \to x^\alpha$ as $t \to \infty$ or $t \to 0$ respectively for any $x > 0$. We write $g \in$ RV$_\infty^\alpha$ or $g \in$ RV$_0^\alpha$ respectively. If $\alpha = 0$, then $g$ is said to be slowly varying. A probability distribution $F$ with upper endpoint $x^* = \infty$ is regularly varying with index $\alpha \geq 0$ if $\bar{F} \in$ RV$_\infty^\alpha$. If $x^* < \infty$, then $F$ is regularly varying at $x^*$ with index $\alpha$ if $\bar{F}(x^* - \cdot) \in$ RV$_0^\alpha$.

**Definition 3** (Exponential-tailed distributions (ET$_\alpha$, ET$_{\alpha,\beta}$)) The distribution $F$ with upper endpoint $x^* = \infty$ is exponential-tailed with rate $\alpha \geq 0$ if for any $x > 0$, $\bar{F}(t + x)/\bar{F}(t) \to \exp(-\alpha x)$, $t \to \infty$. If $\alpha > 0$ and $\bar{F}(x) = r(x)\exp(-\alpha x)$, $r \in$ RV$_0^\infty$, we write $F \in$ ET$_{\alpha,\beta}$. 
By definition, \( F \in ET_\alpha \) with \( \alpha \geq 0 \) if and only if \( \bar{F}(\log(\cdot)) \in RV^{\infty}_{-\alpha} \). The class \( ET_{\alpha,\beta} \) with \( \beta > -1 \) is referred to as gamma-tailed distributions. Another important subclass of \( ET_\alpha \) are the convolution-equivalent distributions.

**Definition 4** (Convolution-equivalent distributions \((CE_\alpha)\)) The distribution \( F \) is convolution equivalent with index \( \alpha \geq 0 \) if \( F \in ET_\alpha \) and \( F \ast F(x)/F(x) \to 2 \int_{-\infty}^{\infty} \exp(\alpha x)F(dx) < \infty \). We write \( F \in CE_\alpha \). We refer to the class \( CE_0 \) as subexponential distributions.

**Definition 5** (Weibull- and log-Weibull tailed distributions \((WT_\beta, LWT_\beta)\)) The distribution \( F \) is Weibull-tailed with index \( \beta > 0 \) if there exist \( \alpha > 0, \gamma \in \mathbb{R}, \) and \( r \in RV^\infty_\gamma \) such that \( F(x) \sim r(x)\exp(-\alpha x^\beta) \). \( F \) is log-Weibull-tailed with index \( \beta > 0 \) if \( F(\exp(\cdot)) \in WT_\beta \).

We remark that some authors define heavy tails to be synonymous with regularly varying tails for which the tail index \( \alpha > 0 \) (e.g. Resnick (2007)). The definition that we use is broader, and includes distributions such as the log-Gaussian, as well as regularly varying tails. In practice, all of the heavy tailed distributions that we treat belong to the class of subexponential distributions, \( CE_0 \).

## 2 Constrained angular variables

We focus firstly on the case where \( \mathcal{W} \) is defined by a norm \( \nu \); specifically let \( \mathcal{W} = \{(w_1, w_2) \in \mathbb{R}_+^2 : \nu(w_1, w_2) = 1\} \). Other types of constrained spaces may sometimes be of interest, but norm spheres are a common restriction, and this focus allows greater generality in other aspects. In particular, all components of the vector are bounded in absolute value when the value of the norm is fixed. We examine the extremal dependence based on the heaviness of the tail of \( R \). Because the \((W_1, W_2)\) are bounded, and subject to additional mild assumptions, we can classify \( R \) according to its MDA in this section.

The case where \( R \) belongs to the Fréchet MDA is the least delicate: as long as \( R \) has a much heavier tail than each of \((W_1, W_2)\), results do not depend strongly on other considerations. No equality in distribution is assumed between \( W_1, W_2 \) in this case. When \( R \) is in the Gumbel or negative Weibull MDA, the shape of the norm \( \nu \) becomes important, and some minor additional regularity conditions are assumed, detailed in Section 2.2.

### 2.1 Radial variable in Fréchet MDA

Many of the most familiar results in the literature on extremal dependence concern the case when \( R \) is in the Fréchet MDA; this is equivalent to regular variation of the tail of \( R \), namely \( \bar{F}_R \in RV^{\infty}_{-1/\xi}, \xi > 0 \), where \( \alpha = 1/\xi \) is called the tail index. A classical example of this is the (multivariate) Pareto copula, which can be constructed as in Eq. 1 with \( R \) standard Pareto, and \( \mathcal{W} = \{(w_1, w_2) \in \mathbb{R}_+^2 : \max(w_1, w_2) = 1\} \) (Ferreira and de Haan 2014). Pareto copulas can be identified with so-called extreme
value copulas, which arise as the limiting copulas of suitably normalized componentwise maxima; see e.g. Rootzén et al. (2018). The next result provides the general form of the tail dependence coefficient for these models.

**Proposition 1** (R in Fréchet MDA) Let \( F_R \in RV^{\infty}_\alpha, \alpha \geq 0, P(W_1 > 0) = P(W_2 > 0) = 1, \) and \( E(W_j^{\alpha+\varepsilon}) < \infty, j = 1, 2, \) for some \( \varepsilon > 0. \) Then \( \eta_X = 1, \) and \( \chi_X = E\left\{ \min \left\{ W_1^{\alpha}/E(W_1^{\alpha}), W_2^{\alpha}/E(W_2^{\alpha}) \right\} \right\}. \) (4)

**Remark 1** When \( F_R(r) \sim Cr^{-\alpha} \) for some \( C > 0, \) then the condition \( E(W_j^{\alpha+\varepsilon}) < \infty \) can be replaced by \( E(W_j^{\alpha}) < \infty, \) by Lemma 2.3 of Davis and Mikosch (2008).

**Remark 2** The condition \( E(W_j^{\alpha+\varepsilon}) < \infty \) is guaranteed when \( W \) is the unit sphere of a norm \( \nu; \) Proposition 1 notably also covers the case where \( (W_1, W_2) \in \mathbb{R}_+^2. \)

**Remark 3** The result includes the case \( \alpha = 0, \) although the tail of such an \( R \) is too heavy to be in any domain of attraction. In this case, \( \chi_X = 1, \) representing perfect upper tail dependence. This case is discussed further in Section 3.1.

From Eq. 4, we observe that asymptotic dependence arises since \( P(\min(W_1^{\alpha}/E(W_1^{\alpha}), W_2^{\alpha}/E(W_2^{\alpha})) > 0) = 1. \) If the conditions of the Proposition were relaxed to \( P(W_1 > 0), P(W_2 > 0) > 0, \) then it is possible that for \( \alpha > 0, \) \( P(\min(W_1^{\alpha}/E(W_1^{\alpha}), W_2^{\alpha}/E(W_2^{\alpha})) > 0) = 0 \) which would yield asymptotic independence, and then \( \eta_X \) would not be defined. The Fréchet case with one-dimensional \( \mathcal{W} \) is therefore very restricted in its capacity to represent varied asymptotically independent behaviors. A more complete description of tail dependence is given by the exponent function, defined as

\[
V_X(x_1, x_2) = \lim_{t \to \infty} t\left\{1 - F_{X_1}^{-1}\left(1 - 1/(tx_1)\right), X_2 \leq F_{X_2}^{-1}\left(1 - 1/(tx_2)\right)\right\}, \quad x_1, x_2 > 0.
\]

(5)

Small modifications to Proposition 1 yield

\[
V_X(x_1, x_2) = E\left[ \max \left\{ W_1^{\alpha}/(E(W_1^{\alpha})x_1), W_2^{\alpha}/(E(W_2^{\alpha})x_2) \right\} \right].
\]

(6)

The link between \( \chi_X \) and \( V_X(1, 1) \) can be obtained simply by inclusion-exclusion arguments; in particular since \( \min(a, b) = a + b - \max(a, b), \) \( \chi_X = 2 - V_X(1, 1). \) With the assumptions of Proposition 1, the random vector \( (X_1, X_2) \) satisfies the condition of multivariate regular variation, which is equivalent to the existence of the limit in Eq. 5; see Resnick (1987, Section 5.4.2) for details about the notion of multivariate regular variation. While many of the specific examples of random scale constructions presented in this paper satisfy Eq. 5, our general results focus on the behavior along the diagonal where \( x_1 = x_2, \) and we do not aim to provide specific statements about off-diagonal behavior with \( x_1 \neq x_2. \)
Example 1 Let $F_R \in RV_{\infty-1}$, i.e., $\alpha = 1$, and $(W_1, W_2) \in W = \{(w_1, w_2) \in [0, 1]^2 : w_1 + w_2 = 1\}$. Taking $(W_1, W_2) = (W, 1 - W)$ then $W \in [0, 1]$, with $E(W) = 1/2$, is the random variable described by the $L_1$ spectral measure (e.g. Coles and Tawn (1991)). A simple example is the Gumbel or logistic spectral measure, which has Lebesgue density

$$h(w) = \left\{w(1 - w)\right\}^{1/\theta - 2}\left\{(1 - w)^{1/\theta} - 2(1 - \theta)/(2\theta)\right\} \quad \theta \in (0, 1), \quad (7)$$

$$\chi_X = 2 - 2^\theta \quad \text{and} \quad V_X(x_1, x_2) = \left(x_1 - 1/\theta + x_2 - 1/\theta\right)^{\theta}.$$

2.2 Radial variable in Gumbel MDA

Suppose that $R$ is in the Gumbel MDA, with upper endpoint $r^* \in (0, \infty]$ i.e., $\lim_{t \to r^*} F_R(t + r/b(t))/F_R(t) = e^{-r}$, where $b(t)$ is termed the auxiliary function. Such distributions can be expressed as

$$F_R(r) = c(r) \exp\left\{-\int_z^r b(t)\,dt\right\}, \quad (8)$$

where $z < r < r^*$, $c(r) \to c > 0$ as $r \to r^*$, and $a = 1/b$ is absolutely continuous with density $a'$ satisfying $\lim_{t \to r^*} a'(t) = 0$ (e.g. Embrechts et al. (2013), Chapter 3.3). Several distributions in this domain have mass on $\mathbb{R}$, but we suppose here that $R$ is conditioned to be positive, which does not affect the tail behavior. If $r^* = \infty$, we also have (Hashorva 2012) that for any $\lambda > 1$, $\rho \in \mathbb{R}$,

$$\lim_{r \to \infty} (rb(r))^\rho F_R(\lambda r)/F_R(r) = 0. \quad (9)$$

2.2.1 Notation and assumptions for $(W_1, W_2)$

Suppose that $W_1 \overset{d}{=} W_2 \overset{d}{=} W \in [0, 1]$ and $\nu(W_1, W_2) = 1$. To this end, we assume that $\nu$ is a symmetric norm, i.e., $\nu(x, y) = \nu(y, x)$, and scaled to satisfy $\nu(x, y) \geq \max(x, y)$, such that the unit sphere of $\nu$ is contained in that of max, with $\nu(b, 1 - b) = b$ for some $b \geq 1/2$. Let $\tau(z) = z/\nu(z, 1 - z) = 1/\nu(1, 1/z - 1)$. The random variable $Z = W_1/(W_1 + W_2) \in [0, 1]$ has distribution symmetric about $1/2$, and satisfies

$$(W_1, W_2) = (Z, 1 - Z)/\nu(Z, 1 - Z) = (\tau(Z), \tau(1 - Z)). \quad (10)$$

Define $I_v = [b_1, b_2] \subset [1/2, 1]$ as the interval such that $\tau(z) = 1$ for all $z \in I_v$, and $\tau(z) < 1$ for $z \not\in I_v$, and write $\tau(z) = \tau_1(z)$ for $z \in [0, b_1]$, $\tau(z) = 1$ for $z \in [b_1, b_2]$, and $\tau(z) = \tau_2(z)$ for $z \in [b_2, 1]$, with $\tau_1$ strictly increasing and $\tau_2$ strictly decreasing. Figure 1 illustrates $\tau$ for a particular $v$; further illustrations are given in Appendix C. We assume further that
Fig. 1 Left: the unit sphere for a particular norm \( \nu \); centre-left: illustration of \( \tau(z) \) (solid line) and \( \tau(1-z) \) (dashed line) for the same \( \nu \). Centre-right and right: illustration of the unit sphere of \( \nu(x,y) = \theta \max(x,y) + (1-\theta) \min(x,y) \) for two different values of \( \theta \).

(Z1): \( Z \) has a Lebesgue density, \( f_Z \), positive everywhere on \((0,1)\), and that its survival function is regularly varying at 1, with \( F_Z(1-\cdot) \in RV^0_{\alpha_Z}, \alpha_Z > 0 \), and make the following mild regularity assumptions on the norm, \( \nu \), or equivalently \( \tau \):

(N1): The function \( \tau \) is twice (piecewise) continuously differentiable except for finitely many points, at which we only require existence of left and right derivatives of first and second order.

(N2): \( \tau \) is regularly varying as it approaches 1 from either side, i.e., \( 1-\tau_1(b_1-\cdot) \in RV^{0}_{1/\gamma_1} \), and, if \( b_2 < 1 \), \( 1-\tau_2(b_2+\cdot) \in RV^{0}_{1/\gamma_2} \), \( \gamma_j \in (0,1), j = 1,2 \). We label \( \gamma = \min(\gamma_1,\gamma_2) \) with \( \gamma = \gamma_1 \) if \( b_2 = 1 \).

In practice, (N1) and (N2) are satisfied by a wide variety of commonly used norms, and the upper limit of \( \gamma_1, \gamma_2 \leq 1 \) in (N2) is a consequence of convexity of the norm \( \nu \); see Lemma 9 in Appendix A. Note that \( \min(\tau(z), \tau(1-z)) = \begin{cases} \tau(z), & z \in [0,1/2], \\ \tau(1-z), & z \in [1/2,1]. \end{cases} \)

Finally, denote \( \zeta = \tau(1/2) \in [1/2,1] \), so that \( W^\wedge = \min(\tau(Z), \tau(1-Z)) \in [0, \zeta] \).

**Proposition 2 (R in Gumbel MDA)** Assume \( \overline{F}_R \) satisfies (8) and that (N1), (N2) and (Z1) hold. Then:

1. If \( \zeta < 1 \), \( \chi_X = 0 \) and \( \eta_X = \lim_{x\rightarrow r^*} \log \overline{F}_R(x)/\log \overline{F}_R(x/\zeta) \), which is defined only for \( r^* = \infty \).

2. If \( \zeta = 1 \), then \( \eta_X = 1 \). Further, \( b_1 = 1/2 \) and

\[
\chi_X = \begin{cases} 0 & \text{if } b_2 > 1/2, \text{i.e., } P(W = 1) > 0, \\ \frac{2\tau'_2(1/2\_+)}{\tau'_2(1/2\_+) - \tau'_1(1/2\_-)} & \text{otherwise}. \end{cases}
\]

We observe that asymptotic independence arises for \( \zeta < 1 \), with the residual tail dependence coefficient determined by the properties of \( \overline{F}_R \). The following corollary covers an important subclass of distributions in the Gumbel MDA.

**Corollary 1** If \( \zeta < 1 \) and \( -\log \overline{F}_R \in RV^\infty_\delta, \delta \geq 0 \), then \( \eta_X = \zeta^\delta \).
If $\delta = 0$, as in the case of log-normal $R$, then $\eta_X = 1$. Another possibility in the Gumbel MDA is $-\log F_R(x) \sim \exp(x)$, as in the reverse Gumbel distribution, for which $\eta_X = 0$. If $r^* < \infty$, then when $\zeta < 1$ the upper endpoint of $X_\lambda$ is less than that of $X_1$, so $\eta_X$ is not defined.

If $\zeta = 1$, then one has asymptotic independence only if $P(W = 1) = P(Z \in I_\nu) > 0$, which is equivalent to $\nu(x, y)$ behaving locally like the $L_\infty$ norm around the point $x = y$. If $\zeta = 1$ and $P(W = 1) = 0$, then $b_1 = b_2 = 1/2$, and the “pointy” shape of such norms induces asymptotic dependence. The following example illustrates this case.

**Example 2** Let $\nu(x, y) = \theta \max(x, y) + (1 - \theta) \min(x, y)$, $\theta > 1$; see Fig. 1 for an illustration. We have $\zeta = 1$ and $b_1 = b_2 = 1/2$, so we can calculate $\chi_X > 0$ using Proposition 2, by evaluating $\tau_1'(1/2+) = 4\theta$ and $\tau_2'(1/2-).$ This yields $\eta_X = 2(\theta - 1)/(2\theta - 1)$, which is an increasing function of $\theta$; in particular $\eta_X \to 0+$ as $\theta \to +1$, and $\eta_X \to 1-$ as $\theta \to +\infty$.

**Example 3** Let $\nu(x, y) = (x^p + y^p)^{1/p}, p \geq 1$, so that $\zeta = 2^{-1/p} < 1$. In this case $b_1 = b_2 = 1$ and $1 - \tau^{-1}(1 - s) = ps^{1/p}[1 + o(1)]$, i.e., $\gamma = 1/p$. For any $Z$ satisfying (Z1), the conditions of Proposition 2 are satisfied, and $\eta_X = \lim_{x \to r^*} \log F_R(x)/\log F_R(2^{1/p}x)$. As a concrete example, if $F_R(x) = \exp(-x^\delta)$, then $\eta_X = 2^{-1/p}.$

### 2.3 Radial variable in negative Weibull MDA

Suppose that $R > 0$ is in the negative Weibull MDA with upper endpoint $r^* > 0$, i.e.,

$$F_R(r^* - s) = \ell(s)s^{\alpha_R}, \quad \ell \in RV_{\alpha_R}^0, \alpha_R > 0;$$

equivalently $F_R(r^* - \cdot) \in RV_{\alpha_R}^0$. Note that the distribution of $R$ cannot have a point mass on $r^*$. The general assumptions for $(W_1, W_2)$ are the same as in Section 2.2.

**Proposition 3** ($R$ in negative Weibull MDA) Assume $F_R(r^* - \cdot) \in RV_{\alpha_R}^0$ and that (N1), (N2) and (Z1) hold. Then:

1. If $\zeta < 1$, $\chi_X = 0$ and $\eta_X$ is not defined.
2. If $\zeta = 1$, then $b_1 = 1/2$ and

$$\chi_X = \begin{cases} 0 & \text{if } P(W = 1) > 0, \\ 2\tau_2'(1/2+) & \text{otherwise}, \end{cases} \quad \eta_X = \begin{cases} \alpha_R & \text{if } P(W = 1) > 0, \\ 1/1 + \alpha_R & \text{otherwise}. \end{cases}$$

**Example 4** Let $\nu(x, y) = \max(x, y)$, so that $\zeta = 1$, $b_1 = 1/2$, $b_2 = 1$ and $P(W = 1) = 1/2$. For $F_R = (1 + \lambda r^*)_+^{-1/\lambda}$, $\lambda < 0$ with $r^* = -1/\lambda$, Proposition 3 gives $\eta_X = (1 - \lambda)^{-1}$, noting $\alpha_R = -1/\lambda$. This represents (part of) a model given in Wadsworth et al. (2017).
Table 1 summarizes the tail dependence for \((X_1, X_2)\) using the norms from Examples 2–4, under different tail behaviors for \(R\).

3 Unconstrained angular variables

We now treat the case where the support \(W\) is two-dimensional. As noted in Section 1, there are cases where \((W_1, W_2)\) itself might have a random scale representation, and by redefining the scaling variable we get back to the situation of one-dimensional \(W\). We thus focus on constructions where this is not necessarily the case. To avoid additional complications we assume throughout this section that \(W_1\) and \(W_2\) share the common marginal distribution \(F_W\). We also generally assume that the tail dependence coefficient \(\chi_W\) and the residual tail dependence coefficient \(\eta_W\) of \((W_1, W_2)\) exist, although some results may still be obtained with the latter undefined.

In Section 2, the constraints imposed by \(W\) being a unit sphere gave bounded marginal distributions for \(W_j, j = 1, 2\), and deterministic dependence between \((W_1, W_2)\). For two-dimensional \(W\), the variety of marginal and dependence behaviors possible for \((W_1, W_2)\) means that systematic characterization according only to the MDA of \(R\) is more difficult. In fact, we need to consider different tail decays of both the radial variable \(R\) and the angular variable \(W\) since the combination of the two is crucial to classify the extremal dependence of \((X_1, X_2) = R(W_1, W_2)\). We focus on some interesting sub-classes that still incorporate a wide variety of structures and cover most of the parametric univariate distributions available for \(R\) and \(W\).

This section is structured according to the tail heaviness assumed for \(R, W\), or both of them. In decreasing order we consider distributions with superheavy tails, regularly varying distributions, distributions of log-Weibull and Weibull type, and finally distributions with finite upper endpoint in the negative Weibull domain of attraction. Table 2 summarizes the general results developed in the following, and Table 3 contains the extremal dependence coefficients for all combinations of tail decays of \(R\) and \(W\) for the specific, yet interesting example where \(W_1\) and \(W_2\) are independent.

3.1 Superheavy-tailed variables

Suppose that \(R\) or \(W\) is superheavy-tailed, i.e., \(\log R\) or \(\log W\) is heavy-tailed. This case naturally arises when considering random location constructions \(\log R + (\log W_1, \log W_2)\); we thus further assume \(W > 0\) so that \(\log W_j, j = 1, 2\), are well defined.

Proposition 4 (Superheavy-tailed variables)

1. If \(F_{\log R} \in CE_0\) and \(F_W(x)/F_R(x) \to c > 0\) as \(x \to \infty\), then \(\eta_X = 1\) and

   \[
   \chi_X = (1 + c \chi_W)/(1 + c) > 0. \quad (11)
   \]

2. If \(F_{\log W} \in CE_0\) and \(F_R = o(F_W)\), then \(\chi_X = \chi_W\). If further \(F_{\log R} \in CE_0\) and
### Table 1

\( (a) \) \( F_{\log W_\lambda} \in CE_0 \) with \( \bar{F}_R(x)/\bar{F}_{W_\lambda}(x) \leq C \) for a constant \( C > 0 \) as \( x \to \infty \), then \( \eta_X = \eta_W \);
\( (b) \) \( \bar{F}_{W_\lambda} = o(\bar{F}_R) \), then, provided the limit exists,

\[ \eta_X = \lim_{x \to \infty} \log \bar{F}_W(x)/\log \bar{F}_R(x). \]

Example 5 (Independence model)  In order to illustrate the results of this section, we consider the example where \( R, W_1 \) and \( W_2 \) are independent. In this case \( \bar{F}_{W_\lambda} = (\bar{F}_W)^2, \chi_W = 0 \) and \( \eta_W = 1/2 \). If \( F_{\log R} \in CE_0 \) and \( \bar{F}_W(x)/\bar{F}_R(x) \to c \geq 0 \) as \( x \to \infty \), then Proposition 4(1) yields asymptotic dependence in \((X_1, X_2)\) with \( \chi_X = (1 + c)^{-1} \). Hence if \( F_{\log R} \in CE_0 \) and \( W \) has a comparable tail, then \( \chi_X \in (0, 1) \), whilst if \( W \) has tail lighter than superheavy, then \( \chi_X = 1 \). On the other hand, if \( W \) is superheavy-tailed with \( F_{\log W} \in CE_0 \), then \( W_\lambda \) is also superheavy-tailed. If \( R \) has lighter tail than \( W_\lambda \), then \( \bar{F}_R(x) \leq C\bar{F}_{W_\lambda}(x) \) for large \( x \) with some \( C > 0 \), and by Proposition 4(2a) we have \( \chi_X = 0 \) and \( \eta_X = 1/2 \). The case \( \chi_X \neq \eta_W \) may arise when the tail of \( W \) dominates the tail of \( R \) and the tail of \( R \) dominates the tail of \( W_\lambda \). For a concrete example, consider log-Weibull tails in \( W \) and \( R \) with \( \bar{F}_W(\exp(x)) \sim \exp(-x^\beta) \) and \( \bar{F}_R(\exp(x)) \sim \exp(-(1+c)x^\beta) \), where \( 0 < \beta, c < 1 \). Then, \( \eta_X = (1 + c)^{-1} \) according to Proposition 4(2b). The first row and column of Table 3 summarize these results.
The values of $\chi_X$ and $\eta_X$ for $(X_1, X_2) = R(W_1, W_2)$ with $W_1, W_2 \overset{d}{=} W$ independent, with different tail decay rates of the radial and angular variables.

| Angle $W$ | Super-heavy | Reg. varying | log-Weibull ($\beta_W > 1$) | Weibull | Neg. Weibull |
|-----------|-------------|--------------|-----------------------------|---------|--------------|
| Radius $R$ | $\chi_X = (1 + c)^{-1}$ | $\chi_X = 1$ | $\chi_X = 1$ | $\chi_X = 1$ | $\chi_X = 1$ |
| Super-heavy | $\eta_X$: Prop. 4(2) | $\alpha_R < \alpha_W: \chi_X = (4) > 0$ | $\chi_X = (4) > 0$ | $\chi_X = (4) > 0$ | $\chi_X = (4) > 0$ |
| Reg. varying | * | $\alpha_R = \alpha_W$: Prop. 6 | $\eta_X = \alpha_W / \alpha_R$ | $\alpha_R > 2\alpha_W: \eta_W = 1/2$ | $\alpha_R > 2\alpha_W: \eta_W = 1/2$ |
| log-Weibull | * | * | $\beta_R = \beta_W: \eta_X = (14)$ | unknown | $\chi_X = 0$ |
| ($\beta_R > 1$) | * | * | unknown | $\eta_X = 2^{-\beta_R/(\beta_R + \beta_W)}$ | $\chi_X = 0$ |
| Weibull | * | * | * | unknown | $\eta_X = 1$ |
| Neg. Weibull | * | * | * | * | $\eta_X = \frac{\alpha_W + \alpha_R}{2\alpha_W + \alpha_R}$ |

The *'s indicate that multiplication with $R$ does not change the tail dependence of $(W_1, W_2)$, i.e., $\chi_X = \chi_W = 0$ and $\eta_X = \eta_W = 1/2$. The combinations of Weibull and log-Weibull tails remain open problems.
3.2 Regularly varying variables

In this section we consider the case where $R$, $W$ or both of them are regularly varying. When $R$ is regularly varying with index $\alpha_R > 0$ and $E(W^{\alpha_R + \varepsilon}) < \infty$ for some $\varepsilon > 0$, then the tail dependence coefficient $\chi_X$ is as described in Proposition 1 in Section 2.1. We firstly consider the case where $W$ is regularly varying with index $\alpha_W > 0$ and $E(W^{\alpha_R}) < \infty$ for some $\varepsilon > 0$. Then the tail dependence coefficient $\chi_X$ is as described in Proposition 1 in Section 2.1. We firstly consider the case where $W$ is regularly varying with index $\alpha_W > 0$ and $R$ is lighter tailed, i.e., either also regularly varying with $\alpha_R > \alpha_W$ or even lighter tailed such as distributions in the Gumbel or negative Weibull domain of attraction. Secondly, we study the case where both $R$ and $W$ are regularly varying with the same index $\alpha_W = \alpha_R$, which turns out to be particularly involved and which requires additional assumptions.

Proposition 5 (W regularly varying with R lighter) Let $\bar{F}_R \in RV_{-\alpha_R}^\infty$, $\alpha_R \geq 0$, and suppose that either $\bar{F}_W \in RV_{-\alpha_W}^\infty$ with $\alpha_W > \alpha_R$, or $R$ is in the Gumbel or negative Weibull domain of attraction; denote the latter case by $\alpha_R = +\infty$. Then $\chi_X = \chi_W$ and

$$\eta_X = \begin{cases} \alpha_W / \alpha_R, & \text{if } \alpha_R < \alpha_W / \eta_W, \eta_W = 0 \text{ or } \eta_W \text{ not defined}, \\ \eta_W, & \text{if } \alpha_R > \alpha_W / \eta_W \text{ or } \alpha_R = +\infty. \end{cases}$$

(12)

The case where $R$ and $W$ are regularly varying with the same index $\alpha > 0$ leads to various scenarios for the extremal dependence in $(X_1, X_2)$. Since $\bar{F}_R, \bar{F}_W \in RV_{-\alpha}^\infty$ is equivalent to $F_{\log R}, F_{\log W} \in ET_{\alpha}$, and ET $\alpha$ is closed under convolutions, we have that $F_{\log X} \in ET_\alpha$ (Watanabe (2008), Lemma 2.5).

Proposition 6 (Regularly varying $R$ and $W$ with the same index) Let $\bar{F}_R, \bar{F}_W \in RV_{-\alpha}^\infty$ with $\alpha > 0$. Then $\eta_X = 1$, and we have the following:

1. If $F_{\log R} \in CE_\alpha$, and if $F_{\log W}(x)/F_R(x) \to c \geq 0$ as $x \to \infty$, then

$$\chi_X = \frac{E(W^{\alpha_W}) + c \chi_W E(R^{\alpha_R})}{E(W^{\alpha_R}) + c E(R^{\alpha_R})}.$$

2. If $F_{\log W} \in CE_\alpha$ and $\bar{F}_R = o(\bar{F}_W)$, then $\chi_X = \chi_W$.

3. Let $F_{\log R} \in ET_{\alpha, \beta_R}$ with $\beta_R \geq -1$ and $E(R^{\alpha_R}) = \infty$ if $\beta_R = -1$, and let $F_{\log W} \in ET_{\alpha, \beta_W}$.

   (a) If $\chi_W > 0$ and if either $\beta_W > -1$ or $\beta_W = -1$ and $E(W^{\alpha_W}) = \infty$, then $\chi_X = \chi_W$.

   (b) If $\chi_W \geq 0$ and if either $\beta_W < -1$ or $\beta_W = -1$ and $E(W^{\alpha_W}) < \infty$, then $\chi_X = E(W^{\alpha_W})/E(W^{\alpha_R})$.

   (c) If $\beta_R > -1$, $\beta_W > -1$ and $E(W^{\alpha_W + \varepsilon}) < \infty$ for some $\varepsilon > 0$, then $\chi_X = 0$.

Remark 4 Proposition 6 contains certain results of Proposition 4 as a special case when allowing for $\alpha = 0$. Proposition 6(1),(2) treats the case of convolution-equivalent tails in $\log R$ or $\log W$, which are relatively light since the expectation $E(R^{\alpha_R})$ or $E(W^{\alpha_R})$ is finite; notice that ET $\alpha, \beta$ with $\beta < -1$ is an important subclass of CE $\alpha$, see Lemma 2.3 of Pakes (2004). The tail of $R$ is not dominated by that of $W$. 

© Springer
in Proposition 6(1), while it is dominated in Proposition 6(2). Proposition 6(3) shifts focus to relatively heavy tails in $R$ with $E(R^{\alpha}) = \infty$, such as the gamma tails of $E_{\alpha,\beta}$ with $\beta > -1$.

Example 6 (Independence model) We continue Example 5, where now $W_1$ and $W_2$ are independent and regularly varying with index $\alpha_W$, and $R$ is regularly varying with index $\alpha_R$. If $\alpha_R < \alpha_W$, then we have asymptotic dependence with $\chi_X$ given in Eq. 4. The same is true in general when $W$ has a lighter tail than $R$ that is not necessarily regularly varying. By Proposition 5, if $\alpha_R < \alpha_W / 2$, then $(X_1, X_2)$ is asymptotically independent with $\eta_X = \alpha_W / \alpha_R$, and if $\alpha_R > 2\alpha_W$, then $\eta_X = 1/2$. In general, if $R$ is even lighter tailed, it does not affect the coefficients $\chi_X$ and $\eta_X$. If $\alpha_R = \alpha_W = \alpha$, then $\eta_X = 1$ and different scenarios for $\chi_X$ arise depending on the distributions of $R$ and $W$: see Proposition 6. Suppose $\alpha > 0$; since $\overline{F}_{W_{\wedge}} \in RV_{-2\alpha}$, $\overline{F}_{X_{\wedge}} \sim E(W_{\alpha}^\wedge)F_{R}$, and so $\chi_X = E(W_{\alpha}^\wedge)/c > 0$ if $\overline{F}_X \sim c\overline{F}_R$ for some $c > 0$. In particular, $c = E(W_{\alpha}^\wedge)$ if $F_W \in ET_{\alpha,\beta_W}$ and $F_R \in ET_{\alpha,\beta_R}$ with $\beta_W < \beta_R$ and $\beta_W < -1$. This fills the second row and column of Table 3.

3.3 Log-Weibull-type variables

In this and the following section we concentrate on radial and angular variables in the Gumbel domain of attraction. Due to the large variety of distributions in this domain we consider subsets that include the most commonly used distribution families. We firstly study the case where both $R$ and $W$ are log-Weibull-tailed; equivalently, log $R$ and log $W$ are Weibull-tailed. We recall that a random variable $Y$ is log-Weibull-tailed if

$$ FY(y) = \ell(y)\log(y)^{\gamma} \exp\left(-\alpha(y)^{\beta}\right), \quad \ell \in RV_0^{\infty}, \gamma \in \mathbb{R}, \alpha, \beta > 0, $$

and we write $F_Y \in LWT_{\beta}$. The parameter $\beta$ has the predominant influence on the tail decay rate, with $\beta = 1$ if and only if $F_Y \in RV_{-2\alpha}^{\infty}$, while $\beta < 1$ gives superheavy-tailed $F_Y$, and $\beta > 1$ yields rapid variation of $Y$, i.e., $F_Y \in RV_{-\infty}^{\infty}$. In the following, we denote the $\beta$-parameters of $R$ and $W$ by $\beta_R$ and $\beta_W$, respectively. The superheavy-tailed case, $\beta_R < 1$ or $\beta_W < 1$, is already covered by Section 3.1, and the case of regularly varying tails with $\beta_R = 1$ or $\beta_W = 1$ is treated in Section 3.2.

We therefore study the remaining case $\beta_R > 1$ and $\beta_W > 1$, which encompasses important distributions such as the log-Gaussian. As in Section 3.1, it is more intuitive to consider the random location construction $\log R + \log(W_1, W_2)$, where we can apply convolution-based results. When independent heavy-tailed summands are involved in the convolution, typically only one of the values of summands has a dominant contribution to a high values of the sum, resulting in relatively simple formulas; see Section 3.1. On the contrary, in the light-tailed set-up all summands may contribute significantly when high values arise in the sum, rendering the tail analysis more intricate. Only relatively few general results on convolutions with tails lighter than exponential are available in the literature. The following lemma will be useful for this and the next section.
Lemma 1 Let \((W_1, W_2)\) be a random vector with \(W_j \sim F_{W_j}, j = 1, 2\), such that both \(F_W \in \mathcal{W}_B\) and \(F_{W,\wedge} \in \mathcal{W}_B\), with other parameters also indexed by \(W\) and \(W,\wedge\).

1. If \(\beta_{W,\wedge} = \beta_W, \alpha_{W,\wedge} = \alpha_W\), then, provided the limit exists, 
   \[ \chi_W = \lim_{x \to \infty} \frac{\ell_{W,\wedge}(x)x^{\gamma_{W,\wedge}}}{\ell_W(x)x^{\gamma_W}}. \]

2. If \(\beta_{W,\wedge} = \beta_W, \text{ then } \eta_W = \alpha_W / \alpha_{W,\wedge}. \)

3. If \(\beta_{W,\wedge} > \beta_W, \text{ then } \log F_W = o(\log F_{W,\wedge}), \text{ and } \eta_W \text{ is not defined.} \)

Remark 5 The proof of Lemma 1 is straightforward from Eq. 13. It also covers the case where \(W\) and \(W,\wedge\) are log-Weibull-tailed, since the tail and residual tail dependence coefficients are invariant under monotonic marginal transformations.

We consider the set-up where the components \(R, W\) and \(W,\wedge\) are log-Weibull-tailed with the same coefficient \(\beta > 1\) and a simplified form of the slowly varying function \(\ell\) by assuming that it is asymptotically constant, i.e., \(\ell(x) \sim c > 0\).

Proposition 7 (Light-tailed random location with \(F_R \in \mathcal{L}_B, \beta > 1\)) Suppose that \(F_R, F_W, F_{W,\wedge} \in \mathcal{L}_B\) with possibly different parameters \(\alpha, \gamma\) indexed by the corresponding \(R, W\) and \(W,\wedge\), but where \(\beta = \beta_R = \beta_W = \beta_W,\wedge > 1\). Assume that the slowly varying functions \(\ell\) behave asymptotically like positive constants.

1. If \(\chi_W > 0\), then \(\chi_X = \chi_W > 0\).

2. If \(\chi_W = 0\), then \(\chi_X = 0\) and
   \[ \eta_X = \eta_W \times \left(\frac{\alpha_{W,\wedge}^{1/(\beta - 1)} + \alpha_R^{1/(\beta - 1)}}{\alpha_W^{1/(\beta - 1)} + \alpha_R^{1/(\beta - 1)}}\right)^{\beta - 1}, \]
   where \(\eta_W = \alpha_W / \alpha_{W,\wedge}\), and \(\eta_X = \eta_W\) if \(\alpha_W = \alpha_{W,\wedge}\).

Example 7 (Gaussian factor model) Suppose that \(\log R\) is univariate standard Gaussian and that \(\log (W_1, W_2)\) is bivariate standard Gaussian, independent of \(R\) and with Gaussian correlation \(\rho_W \in (-1, 1)\). Then we have log-Weibull tails with parameters \(\beta_R = \beta_W = \beta_{W,\wedge} = 2, \alpha_R = \alpha_W = 1/2\) and \(\alpha_{W,\wedge} = 1/(1 + \rho_W)\) (see Example 9). Applying Eq. 14 gives \(\eta_X = \eta_W \times (3 + \rho_W)/(2(1 + \rho_W)) = (3 + \rho_W)/4\).

Example 8 (Independence model) As in Examples 5 and 6 we let \(R, W_1\) and \(W_2\) be independent, and we now assume that they are log-Weibull-tailed with equal \(\beta\) parameter. By independence, \(F_{W,\wedge} \in \mathcal{L}_B\) with \(\alpha_{W,\wedge} = 2\alpha_W\). Proposition 7 gives \(\chi_X = 0\) with \(\eta_X\) calculated by formula (14).

3.4 Weibull-type variables

We now consider the case where \(R\) and \(W\) follow a Weibull-type distribution, a rich class in the Gumbel MDA. Recall that a variable \(Y\) is of Weibull-type, \(F_Y \in \mathcal{W}_\beta\), if

\[ F_Y(y) = \ell(y)y^\gamma \exp(-\alpha y^\beta), \quad \ell \in \mathcal{R}_\infty^\gamma, \gamma \in \mathbb{R}, \alpha, \beta > 0. \]
Well-known examples of Weibull-tailed distributions are the Gaussian with \( \beta = 2 \), the gamma with \( \beta = 1 \) or, more generally, the Weibull where \( \beta \) is called the Weibull index.

For developing useful results, we further assume that, in addition to \( R \) and \( W \), \( W_\wedge \) also has a Weibull-type tail. As previously, we index the corresponding \( \ell \) functions and the parameters \( \alpha, \gamma \) in Eq. 15 by the variable name. We also recall Lemma 1 concerning the dependence coefficients of the vector \((W_1, W_2)\).

**Proposition 8** (Weibull-type variables) Suppose that \( F_R \in WT_{\beta_R}, F_W \in WT_{\beta_W} \) and \( F_{W_\wedge} \in WT_{\beta_{W_\wedge}} \). We have the following hierarchy of dependence structures:

1. If \( \beta_{W_\wedge} = \beta_W, \alpha_{W_\wedge} = \alpha_W, \gamma_{W_\wedge} = \gamma_W \), then \( \chi_X = \chi_W = \lim_{x \to \infty} \ell_{W_\wedge}(x)/\ell_W(x) \), if the limit exists, and \( \eta_X = \eta_W = 1 \).
2. If \( \beta_{W_\wedge} = \beta_W, \alpha_{W_\wedge} = \alpha_W, \gamma_{W_\wedge} < \gamma_W \), then \( \chi_X = 0 \) and \( \eta_X = \eta_W = 1 \).
3. If \( \beta_{W_\wedge} = \beta_W, \alpha_{W_\wedge} > \alpha_W \), then \( \chi_X = 0 \) and
   \[ \eta_X = \eta_W^{\beta_R/(\beta_R+\beta_W)} = \left(\alpha_W/\alpha_{W_\wedge}\right)^{\beta_R/(\beta_R+\beta_W)} \, . \]
4. If \( \beta_{W_\wedge} > \beta_W \), then \( \chi_X = 0 \) and \( \eta_X = \eta_W = 0 \).

In all of the cases encompassed by Proposition 8, \((X_1, X_2)\) and \((W_1, W_2)\) have the same tail dependence coefficient \( \chi \), which can be positive only in case 1. In all other cases the variables are asymptotically independent, and only in case 3 the residual tail dependence coefficient \( \eta \) changes under the multiplication of the radial variable \( R \). Since \( \beta_R/(\beta_R+\beta_W) \in (0, 1) \), this always leads to an increase in dependence, that is, \( \eta_X > \eta_W \).

**Example 9** (Gaussian scale mixtures) To illustrate the most interesting case 3 in Proposition 8 we consider \((W_1, W_2)\) following a bivariate Gaussian distribution with standardized margins and correlation \( \rho_W \). We have that

\[
\overline{F}_W(x) \sim r_W(x) \exp(-x^2/2), \quad \overline{F}_{W_\wedge}(x) \sim r_{W_\wedge}(x) \exp\{-x^2/(1+\rho_W)\},
\]

where the tail distribution of the minimum follows from bounds on the multivariate Mills ratio (e.g. Hashorva and Hüsler (2003)), and \( r_W \) and \( r_{W_\wedge} \) are regularly varying functions. Therefore, \( \eta_W = (1 + \rho_W)/2 \) and Proposition 8 confirms Huser et al. (2017, Theorem 2) where

\[
\eta_X = \eta_W^{\beta_R/(\beta_R+2)} = \left((1 + \rho_W)/2\right)^{\beta_R/(\beta_R+2)} \, .
\]

**Example 10** (Independence model) We continue the example where \( R, W_1 \) and \( W_2 \) are independent, and they are now assumed to be Weibull-tailed. The variable \( W_\wedge \) is also Weibull-tailed with \( \beta_{W_\wedge} = \beta_W \) and \( \alpha_{W_\wedge} = 2\alpha_W \). Therefore, the third part of Proposition 8 entails that \( \eta_X = 2^{-\beta_R/(\beta_R+\beta_{W_\wedge})} \). This expression tends to 1/2 if \( \beta_R/\beta_W \to \infty \) such that the tail of \( W \) dominates strongly with respect to that of \( R \); if \( \beta_R/\beta_W \to 0 \), then \( \eta_X \to 1 \).
3.5 Variables in the negative Weibull domain of attraction

The remaining cases are those where \( R, W \) or both of them are in the negative Weibull MDA, with finite upper endpoint. Recall that a variable \( Y \) is in the negative Weibull MDA if

\[
F_Y(y^*-s) = \ell(s)s^{\alpha}, \quad \ell \in \mathbb{R}^0, \alpha > 0.
\]  

(16)

The case where \( R \) is superheavy-tailed or regularly varying and \( W \) satisfies (16) has been covered in part 1 of Propositions 1 and 4, respectively. On the other hand, the case where the tail of \( R \) satisfies (16) and \( W \) is superheavy-tailed or regularly varying is treated by part 2 of Propositions 4 and 5, respectively. It remains to study the situation where one of \( R \) or \( W \) is of form (16), and the other is in the Gumbel domain of attraction as defined in Eq. 8. In this section we focus on the case where \( W \bigwedge \) has the same upper endpoint as \( W \); for a more detailed study where \( W \bigwedge \) can have a smaller upper endpoint, and \( W \) may have a point mass on its upper endpoint, see Section 2.

**Proposition 9** (Variables in the negative Weibull MDA) 1. Suppose that \( R \) is in the Gumbel MDA with upper endpoint \( r^* \in (0, \infty) \) and that \( W \) and \( W \bigwedge \) satisfy (16) with common endpoint \( w^* \) and parameters \( \alpha_W \) and \( \alpha_W \bigwedge \), respectively. Then \( \chi_X = \chi_W \) and \( \eta_X = 1 \).

2. Let \( R \) satisfy (16) with upper endpoint \( r^* \) and let \( W \) and \( W \bigwedge \) be in the Gumbel MDA with equal upper endpoint \( w^* \in (0, \infty) \) and auxiliary functions \( b_W \) and \( b_W \bigwedge \), such that \( \lim_{x \to w^*} b_W(x)/b_W \bigwedge (x) \) exists. Then \( \chi_X = \chi_W \) and \( \eta_X = \eta_W \).

3. Let \( R, W \) and \( W \bigwedge \) all satisfy (16) with endpoints \( r^*, w^*, w^* \) and parameters \( \alpha_R, \alpha_W \) and \( \alpha_W \bigwedge \), respectively. If \( \alpha_W = \alpha_W \bigwedge \) then \( \chi_X = \chi_W \) and \( \eta_X = 1 \). If \( \alpha_W \bigwedge > \alpha_W \) then \( \chi_X = \chi_W = 0 \) and

\[
\eta_X = (\alpha_W + \alpha_R)/(\alpha_W \bigwedge + \alpha_R) > \alpha_W/\alpha_W \bigwedge = \eta_W.
\]  

(17)

**Example 11** (Independence model) Continuing the running independence example, we now suppose that \( F_R, F_W \) satisfy (16) with parameters \( \alpha_R, \alpha_W \). Clearly, \( F_W \bigwedge \) also satisfies (16), with parameter \( \alpha_W \bigwedge = 2\alpha_W \). The third part of Proposition 9 shows that

\[
\eta_X = (\alpha_W + \alpha_R)/(2\alpha_W + \alpha_R) \in (1/2, 1),
\]

hence by varying the parameters \( \alpha_R, \alpha_W > 0 \) we can attain the whole range of residual tail dependence coefficients related to positive association.

4 Literature review and examples

Here we present an overview of related literature, detailing how existing examples and results fit into the framework of this paper.

**Elliptical copulas** Let \( \Sigma \) be a positive-definite covariance matrix with Cholesky decomposition \( \Sigma = AA^T \), and \((U_1, U_2)\) be uniformly distributed on the \( L_2 \) sphere \( \{(w_1, w_2) : (w_1, w_2)^T(w_1, w_2) = 1\} \). Then \((X_1, X_2) = RA(U_1, U_2)\) has an elliptical
distribution for any \( R > 0 \) called the generator. Therefore \((W_1, W_2) = A(U_1, U_2)\) lies on the Mahalanobis sphere \( W = \{(w_1, w_2) : (w_1, w_2)^T \Sigma^{-1} (w_1, w_2) = 1\}\), and the extremal dependence in the upper right orthant is unchanged by taking \((W_j)_+ = \max(W_j, 0)\). It is well known that \((X_1, X_2)\) is asymptotically dependent if and only if \( R \) is in the Fréchet MDA (Hult and Lindskog (2002), Theorem 4.3). In that case, the tail dependence coefficient \( \chi \) is given by Eq. 4, with \( W \) replaced by \((W_j)_+\); see also Opitz (2013). For \( R \) in the Gumbel MDA, the scaling condition on \( v \) such that \( \tau(w) \in [0, 1] \) yields \( \Sigma \) with diagonal elements 1, off-diagonal elements \( \rho \in (-1, 1) \), and residual tail dependence coefficient is given by Proposition 2(1) with \( \zeta = \tau(1/2) = \{(1 + \rho)/2\}^{1/2} \). Hashorva (2010) details calculation of \( \eta_X \) assuming \( R \) to be in the Gumbel MDA, providing an alternative perspective on the derivation. The spatial model of Huser et al. (2017) is also covered by this case.

**Example (Gaussian)** The Gaussian distribution arises when \( F_R(r) = e^{-r^2/2} \), so that by Corollary 1, \( \eta_X = \zeta^2 = (1 + \rho)/2 \).

**Archimedean and Liouville copulas** Archimedean (respectively Liouville) copulas arise as the survival copula when \((W_1, W_2)\) is uniformly (respectively Dirichlet) distributed on the positive part of the \( L_1 \) sphere \( W = \{(w_1, w_2) : w_1 + w_2 = 1\}\), and \( R > 0 \). That is, \((X_1, X_2) = R(W_1, W_2)\) has an inverted Archimedean or Liouville copula, whilst the Archimedean or Liouville copula itself is that of \((t(X_1), t(X_2))\), for a monotonic decreasing transformation \( t \). By taking \( t(x) = 1/x \), we obtain \( 1/(X_1, X_2) = (\tilde{X}_1, \tilde{X}_2) = \tilde{R}(\tilde{W}_1, \tilde{W}_2) \), so Archimedean copulas have a random scale representation with \((\tilde{W}_1, \tilde{W}_2)\) constrained by functional dependence that is not represented by a norm.

Archimedean copulas are typically defined in terms of a non-increasing continuous generator function \( \psi : [0, \infty) \to [0, 1] \), such that \( C(u_1, u_2) = \psi(\psi^{-1}(u_1) + \psi^{-1}(u_2)) \). The link between \( \psi \) and the variable \( R \sim F_R \) is given in equation (3.3) of McNeil and Nešlehová (2009); for \( d = 2 \) this is

\[
F_R(r) = \psi(r) - r \psi'(r_+), \quad r > 0,
\]

where \( \psi'(r_+) \) denotes the right-hand derivative of \( \psi \).

Archimedean copulas are a special case of Liouville copulas, whose dependence properties are studied in Belzile and Nešlehová (2018). For \((X_1, X_2)\), their Theorem 1 states that \( R \) in the Fréchet MDA leads to asymptotic dependence, whilst the Gumbel and negative Weibull MDAs lead to asymptotic independence. The exponent function given in their Theorem 1 matches Eq. 6. In their Theorem 2, Belzile and Nešlehová (2018) consider the extremal dependence properties of \( 1/(X_1, X_2) = \tilde{R}(\tilde{W}_1, \tilde{W}_2) \), i.e., the Liouville copula itself. Since the reciprocal of Dirichlet random variables have regularly varying tails, this links with Proposition 5 which states that asymptotic independence arises if \((\tilde{W}_1, \tilde{W}_2)\) themselves are asymptotically independent and heavier-tailed than \( R \). Proposition 6(3c) is relevant if \( \tilde{R} \) and \( \tilde{W} \) are regularly varying with the same index.
The case of \( \psi(\alpha) = e^{-x^\alpha}, \alpha \in (0, 1) \). By Eq. 18, \( \widetilde{F}_R(r) = e^{-r^\theta}(1 + \theta r^\theta) \in \mathbb{W}_\theta \). The copula of \((X_1, X_2)\) is the asymptotically independent inverted Gumbel copula (Ledford and Tawn 1997). We have \( \zeta = \tau(1/2) = 1/2 \) and so \( \eta_X = 2^{-\theta} \) by Corollary 1. The Gumbel copula is that of \( 1/(X_1, X_2) = R(W_1, W_2) \), with \( F_R(r) = e^{-r^\theta}(1 + \theta r^\theta) \), so \( \widetilde{F}_R \in \mathbb{R}V^\infty_\theta \). The dependence structure follows from Proposition 1 for \( \theta < 1 \) since \( E(W_\theta) < \infty \). Noting that \( \tilde{W}_\lambda \) is a bounded random variable, \( \chi_X = 0 \) for \( \theta = 1 \), as given by Proposition 6(3c). In fact, for \( \theta = 1 \), the copula is the independence copula.

**Archimedian copulas** Bivariate Archimedian copulas were introduced by Capéraà et al. (2000) and extended to the multivariate case with a stochastic representation by Charpentier et al. (2014). They are so-called because of a connection to both Archimedean and extreme-value max-stable copulas. Letting \( \psi \) be the generator of an Archimedean copula, and \( V \) the exponent function defined in Eq. 5, a bivariate Archimedean copula can be expressed as \( C(u_1, u_2) = \psi \circ V(1/\psi^{-1}(u_1), 1/\psi^{-1}(u_2)) \), such that taking \( V(x_1, x_2) = 1/x_2 + 1/x_2 \) — corresponding to the independence max-stable copula — yields an Archimedean copula, whilst taking \( \psi(x) = e^{-x} \) yields a max-stable copula. Charpentier et al. (2014) show that the vector \((X_1, X_2) = R(W_1, W_2)\) has an inverted Archimedian copula if \( \widetilde{F}_R \) is as in Eq. 18, and \( P(W_1 \geq w_1, W_2 \geq w_2) = \max(0, 1 - V(1/w_1, 1/w_2)) \). Hence \((\tilde{X}_1, \tilde{X}_2) = 1/(X_1, X_2) = R(W_1, W_2)\) has an Archimedian copula. We have \( \tilde{F}_W(w) \in \mathbb{R}V^\infty \) and \( \chi_{\tilde{W}} = 2 - V(1, 1) \) which is positive unless \( V(x_1, x_2) = 1/x_2 + 1/x_2 \). If \( R \) has a lighter tail then Proposition 5 gives \( \chi_{\tilde{X}} = \chi_{\tilde{W}} \), whilst if \( R \) is the same or heavier, the results of Propositions 1, 4 or 6 are relevant. The inverted case follows similarly to the calculations in Section 2 since the margins of \( W_1, W_2 \) are uniform and the zero-truncation in the copula for \((W_1, W_2)\) means that there is mass on \( \{w \in [0, 1] : V(1/w, 1/(1 - w)) = 1\} \) whenever \( V(1/w_1, 1/w_2) > 1 \), where \( V(1/x_1, 1/x_2) \) defines a norm.

**Example** (Gumbel Archimax) Taking \( V(x_1, x_2) = (x_1^{-1/\theta} + x_2^{-1/\theta})^\theta \), the exponent function of the logistic, then the corresponding Archimedian copula is \( C(u_1, u_2) = \psi((\psi^{-1}(u_1)^{-1/\theta} + \psi^{-1}(u_2)^{-1/\theta})^\theta) \), which is Archimedian with generator \( \psi(x^\theta) \) (Charpentier et al. 2014). If \( \psi(x) = e^{-x^\alpha} \), \( \alpha \in (0, 1) \), then we obtain the Gumbel copula with parameter \( \theta \alpha \). Tail dependence results can then be obtained as in the example above, or considering the Archimedian structure. Following the latter, for \( \tilde{X} \) Proposition 1 gives \( \chi_{\tilde{X}} = 2 - V(1, 1)\alpha = 2 - 2\theta\alpha \), for \( \alpha \in (0, 1) \) whilst Proposition 6(3a) gives the extension to \( \alpha = 1 \). For the inverted copula \( \eta_X = (2^{-\theta})^\alpha \), following similar lines to Proposition 2.

**Multivariate (\( \rho \)-Pareto copulas** Let \( \rho : (0, \infty)^2 \rightarrow (0, \infty) \) be a positive homogeneous function. Multivariate \( \rho \)-Pareto copulas arise when \( \tilde{F}_R(r) = r^{-1} \), i.e. standard Pareto, and the random vector \((W_1, W_2)\) is concentrated on \( \mathbb{W} = \{(w_1, w_2) \in \mathbb{R}_+^2 : \rho(w_1, w_2) = 1\} \) with marginals satisfying \( E(W) < \infty \) (Dombry and Ribatet 2015). The case of \( \rho(x_1, x_2) = \max(x_1, x_2) \) leads to the multivariate Pareto copula associated to multivariate generalized Pareto distributions (Rootzén and Tajvidi 2006;
Ferreira and de Haan 2014; Rootzén et al. 2018). Such copulas are asymptotically dependent, except for the case outlined in Section 2.1, with \( \chi_X \) given by Eq. 4. Although we have focused on norms and \( \rho \) need not be convex, there is nothing in Proposition 1 requiring this.

**Example** (Bivariate Pareto copula associated to the Gumbel copula) Since the Gumbel copula is a max-stable distribution, it has an associated Pareto copula. If \( Z \) has density \( f_Z(z) = h(z) \max(z, 1-z) 2^{1-\theta} \), where \( h \) is given by Eq. 7, then \( (X_1, X_2) = R(W_1, W_2) = R(Z, 1-Z)/\max(Z, 1-Z) \) with \( F_R(r) = r^{-1} \) leads to the associated bivariate Pareto copula. The distribution function of \( (X_1, X_2) \) is

\[
P(X_1 \leq x_1, X_2 \leq x_2) = \{V(\min(x_1, 1)), \min(x_2, 1)) - V(x_1, x_2)\} / V(1, 1),
\]

where \( V(x_1, x_2) = (x_1^{-1/\theta} + x_2^{-1/\theta})^{\theta} \) is the exponent function for the Gumbel distribution.

**Model of de Haan and Zhou (2011)** They describe the losses of two banks by a factor model \( S_j = C + L_j, j = 1, 2 \), where \( F_{L_j} \in RV_{\alpha}^\infty \) and \( F_C \in RV_{-\beta}^\infty \). For \( \beta < \alpha \) they show that \( S = (S_1, S_2) \) is completely asymptotically dependent, i.e., \( \chi_S = 1 \), and for \( \beta = \alpha \) they obtain \( \chi_S \in (0, 1) \). If \( \alpha < \beta < 2\alpha \) asymptotic independence arises with \( \eta_S = \alpha/\beta \), and if \( \beta > 2\alpha \) then \( \eta_S = 1/2 \). Our Proposition 4 yields the same results as special cases with \( R = \exp(C) \) and \( W_j = \exp(L_j), j = 1, 2 \).

**Model of Wadsworth et al. (2017)** They consider the copula induced by taking \( R \) to be generalized Pareto, \( F_R(r) = (1 + \varpi r)^{-1/\lambda} \), and \( W = \{(w_1, w_2) \in [0, 1]^2 : \| (w_1, w_2) \|_\varpi = 1 \} \) where \( \| \cdot \|_\varpi \) is a symmetric norm subject to certain restrictions. These restrictions mean that \( \lambda \leq 0 \) corresponds to asymptotic independence; the residual tail dependence coefficient \( \eta_X \) is as given in Proposition 2 for \( \lambda = 0 \) with \( \zeta = \tau(1/2) = \| (1, 1) \|_\varpi^{-1} \), and Proposition 3 for \( \lambda < 0 \). We note that if the norm \( \nu \) has certain shapes that were excluded in Wadsworth et al. (2017), asymptotic dependence is possible for \( \lambda \leq 0 \). When \( R \) is in the Fréchet MDA (\( \lambda > 0 \)) then asymptotic dependence holds with \( \chi_X \) given by Eq. 4.

**Model of Krupskii et al. (2018)** They consider location mixtures of Gaussian distributions, corresponding to scale mixtures of log-Gaussian distributions. According to their Proposition 1, asymptotic dependence occurs when the location variable is of exponential type, i.e. the scale is of Pareto type; the given \( \chi_X \) can then be obtained via (4). When the location is Weibull-tailed but with shape in \( (0, 1) \), the scale is superheavy-tailed, with \( F_R \in RV_{0}^\infty \), and perfect extremal dependence (\( \chi_X = 1 \)) arises, as noted in Remark 3 following Proposition 1. When the random location is Weibull-tailed with shape in \( (1, \infty) \) then the random scale \( R \) is in the Gumbel MDA and asymptotic independence arises. If \( F_{\log R} \in WT_2 \) has the same Weibull coefficient 2 as the standard Gaussian log \( W \) and as log \( W_\wedge \) (provided that \( \rho = \text{cor}(\log W_1, \log W_2) \in \rho \)
(-1, 1]), then we can apply Proposition 7 to calculate the value of \(\eta_X\) given as

\[
\eta_X = \eta_W \frac{\alpha_{W^\perp} + \alpha_R}{\alpha_W + \alpha_R} = \frac{1 + \rho (1 + \rho)^{-1} + \alpha_R}{2} = \frac{1 + (1 + \rho)\alpha_R}{1 + 2\alpha_R},
\]

which extends the results of Krupskii et al. (2018). Specifically, with standard Gaussian log \(R\) we get \(\eta_X = (3 + \rho)/4\), see Example 7.

**Model of Huser and Wadsworth (2019)** They consider scale mixtures of asymptotically independent vectors where both \(R\) and \(W\) have Pareto margins with different shape parameters. Asymptotic dependence arises when \(R\) is heavier tailed; \(\chi_X\) is then given by Eq. 4, whilst asymptotic independence arises when \(W\) is heavier tailed and \(\eta_X\) is given by Eq. 12. When \(R\) and \(W\) have the same shape parameter, their assumption \(\eta_W < 1\) implies that \(E(W^{\alpha_\perp + \varepsilon}) < \infty\) for some \(\varepsilon > 0\), giving asymptotic independence by Proposition 6(3c).

Various other articles also focus on polar or scale-mixture representations. Hashorva (2012) examines the extremal behavior of scale mixtures when \(R\) is in the Gumbel MDA. He considers both one- and two-dimensional \(W\), both with similarities and differences to our set-up. For one-dimensional \(W\), he assumes a functional constraint of the form \((W_1, W_2) = (W, \rho W + z^*(W))\) for measurable \(z^* : [0, 1] \to (0, \infty); \rho \in (-1, 1)\) (the specification also allows for negative components, but we focus here on the positive part). Constraints to certain norm spheres, such as the Mahalanobis or \(L_p\) norm, could be written in this way, however examples such as the \(L_\infty\) norm could not. Where the representations overlap, our results coincide (e.g., Section 4.3 of Hashorva (2012)). In the case of two-dimensional \(W\), \(W_1\) is assumed bounded, whilst \(W^\perp\) is in the negative Weibull MDA. Although, differently to Hashorva (2012), we typically assume symmetry, there are nonetheless some connections between the results in our Section 3.5 and that paper.

Nolde (2014) provides an interpretation of extremal dependence in terms of a gauge function (see also Balkema and Nolde (2010) and Balkema and Embrechts (2007)), which, loosely speaking, corresponds to level sets of the density in light-tailed margins. The main result of Nolde (2014) (Theorem 2.1) is presented in terms of Weibull-type margins, such that \(-\log F_X \in RV_\delta^\infty, \delta > 0\); in terms of Section 2, this corresponds to \(-\log F_R \in RV_\delta^\infty\). By noting that where the density of \(R, f_R\), exists, the joint density of \((X_1, X_2) = R(\tau(Z), \tau(1 - Z))\) is

\[
f_{(X_1, X_2)}(x_1, x_2) = f_R(v(x_1, x_2))f_Z(x_1/(x_1 + x_2))v(x_1, x_2)/(x_1 + x_2)^2,
\]

the gauge function of \((X_1, X_2)\) is obtained as \(v\) when \(-\log F_R \in RV_\delta^\infty\), using Proposition 3.1 therein. We found \(\eta_X = \zeta^\delta\), with \(\zeta = v(1, 1)^{-1}\), precisely as in Nolde (2014).

Various papers focus on extremal dependence arising from certain types of polar representation, but from a conditional extremes perspective (Heffernan and Tawn 2004; Heffernan and Resnick 2007). This is different to our focus; here we examine the extremal dependence as both variables grow at the same rate. In the conditional approach, different rates of growth may be required in the different components. Abdous et al. (2005) examine conditional limits in the context of elliptical copulas,
whilst Fougères and Soulier (2010) and Seifert (2014) consider the constrained \( W \) case, with \( R \) in the Gumbel MDA.

5 New examples

We present two new constructions that have the desirable property of smoothly interpolating between asymptotic dependence and asymptotic independence, whilst yielding non-trivial structures within each class. By smoothness, we mean that the transition between classes occurs at an interior point, \( \theta_0 \), of the parameter space \( \Theta \), and, assuming increasing dependence with \( \theta \), \( \lim_{\theta \to \theta_0^+} \chi_X = 0 \), \( \lim_{\theta \to \theta_0^-} \eta_X = 1 \).

To our knowledge, the only other models in the literature with this behavior are (i) that of Wadsworth et al. (2017), where \( \nu(x, y) = \max(x, y) \) and \( \overline{F}_R(x) = \left( 1 + \lambda x \right)^{-1/\lambda}, \lambda \in \mathbb{R} \), and (ii) that of Huser and Wadsworth (2019) where \( \overline{F}_R(x) = x^{-1/\delta} \), \( \overline{F}_W(x) = x^{-1/(1-\delta)} \), \( \delta \in (0, 1) \), and \( \eta_W < 1 \). The first example is constructed using constrained \((W_1, W_2)\) (Section 2), where the required ingredients are \( \overline{F}_R, \nu, \) and \( F_Z \), whilst the second uses unconstrained \((W_1, W_2)\) (Section 3) with ingredients \( \overline{F}_R, F_W \) and the dependence structure of \((W_1, W_2)\).

5.1 Model 1

In Propositions 2 and 3, it was demonstrated how the shape of \( \nu \) affects the tail dependence of \((X_1, X_2)\) when \( R \) is in the Gumbel or negative Weibull MDA. In Example 2, a particular norm that yields asymptotic dependence was given; here we extend the parameterization of this norm and use our results to present a new asymptotically (in)dependent copula. Since the cases where \( R \) has finite upper endpoint \( r^* < \infty \) lead to undefined \( \eta_X \), we focus on \( r^* = \infty \).

Proposition 10  Let \( R \) be in the Gumbel MDA with \( r^* = \infty \) and let \( \nu(x, y) = \theta \max(x, y) + (1-\theta) \min(x, y), \theta \geq 1/2 \). Then for \((W_1, W_2)\) defined through Eq. 10 and \( Z \) satisfying the conditions in Section 2.2,

\[
\chi_X = \max(2(\theta - 1)/(2\theta - 1), 0), \eta_X = \lim_{x \to \infty} \log \overline{F}_R(x) / \log \overline{F}_R(x/\min(\theta, 1)).
\]

We note that if \( -\log \overline{F}_R \in \text{RV}_\delta \), for example, then we have a continuous parametric family exhibiting asymptotic dependence for \( \theta > 1 \) with \( \chi_X = 2(\theta - 1)/(2\theta - 1) \), and asymptotic independence for \( \theta \leq 1 \) with \( \eta_X = \theta^\delta \). To make things concrete, we propose the following model.

Model 1

\[
\overline{F}_R(r) = e^{-r^\delta}, \nu(x, y) = \theta \max(x, y) + (1-\theta) \min(x, y), \theta \geq 1/2, Z \sim \text{Beta}(\alpha, \alpha).
\]

The set of models defined in Proposition 10, exemplified by Model 1, has some rather interesting behavior in the extremes. Whilst the limiting quantities \( \chi_X, \eta_X \) are given in Proposition 10, the subasymptotic behavior of \((X_1, X_2)\), in particular the
behavior of the slowly varying function $\ell$ in Eq. 2, is not prescribed by any of the propositions in this paper. Combining Eqs. 2 and 3, define

$$
\chi_x(q) = \Pr(X_1 \geq F_{X_1}^{-1}(q), X_1 \geq F_{X_1}^{-1}(q))/(1 - q) = \ell(1 - q)/(1 - q)^{1/\eta_X - 1},
$$

so that for $\eta_X = 1$, $\chi_x(q) = \ell(1 - q)$. For Model 1 we find that $\chi_x(q)$ is not necessarily monotonic, and may decrease before increasing to a positive limit value. Figure 2 shows $\chi_x(q)$ for various parameterizations of the model. This non-monotonic behavior appears uncommon; to our knowledge there are no well-known theoretical examples of this.

5.2 Model 2

The following proposition collates results from Propositions 1 and 9, and provides a general principle for constructing new dependence models permitting both asymptotic dependence and asymptotic independence.

**Proposition 11** Let $R$ be in the MDA of a generalized extreme value distribution with shape parameter $\xi \in \mathbb{R}$, and let $(W_1, W_2)$ with $W_1 \overset{d}{=} W_2 \overset{d}{=} W$ have $\chi_W = 0$, well-defined $\eta_W \in (0, 1)$, and $F_W(w^* - \cdot) \in R_{\alpha_W}^0$, $\alpha_W > 0$. Then

1. For $\xi > 0$, $\chi_X = E(W_1^{1/\xi})/E(W_1^{1/\xi})$, $\eta_X = 1$,
2. For $\xi = 0$, $\chi_X = 0$, $\eta_X = 1$,
3. For $\xi < 0$, $\chi_X = 0$, $\eta_X = (1 - \xi \alpha_W)/(1 - \xi \alpha_W/\eta_W)$.

![Fig. 2](image)

*Fig. 2* Theoretical $\chi_x(q)$ for Model 1 plotted against $1 - q$ on a logarithmic scale for $q \in [1 - 10^{-1}, 1 - 10^{-7}]$. Different columns show different values of $\theta$; thick horizontal lines show the true limiting values of $\chi_X = (0, 0, 1/3)$ (left-right). Top row: $\delta$ varies within a panel; bottom row: $\alpha$ varies within a panel.

© Springer
The model construction opportunities from Proposition 11 are quite varied; specifically taking $\overline{F}_R$ that permits all three tail behaviors produces a flexible range of models spanning the two dependence classes. We therefore propose the following concrete model, based on our running independence example.

**Model 2**

$$\overline{F}_R(r) = (1 + \xi x)^{-1/\xi}, \xi \in \mathbb{R}, W_1 \perp \perp W_2, W \sim \text{Beta}(\alpha, \alpha).$$

For the special case $\alpha = 1$, i.e., $W \sim \text{Unif}(0, 1)$, one can explicitly calculate $\chi_X$ and $V_X$ as well as $\eta_X$. By Proposition 11, for $\xi < 0$, $\eta_X = (1 - \xi)/(1 - 2\xi)$ with $\lim_{\xi \to 0^-} \eta_X = 1$, and $\chi_X = 0$; for $\xi = 0$, $\chi_X = 0$, $\eta_X = 1$, and for $\xi > 0$, $\chi_X = 2\xi/(2\xi + 1)$, whilst

$$V_X(x_1, x_2) = \min(x_1, x_2)^{-1} + \frac{1}{2\xi + 1} \left( \frac{\min(x_1, x_2)}{\max(x_1, x_2)} \right)^\xi \max(x_1, x_2)^{-1}. \quad (19)$$

The limits of Eq. 19 as $\xi \to 0$ and $\xi \to \infty$ are $x_1^{-1} + x_2^{-1}$ and $\min(x_1, x_2)^{-1}$, corresponding to independence and perfect dependence (e.g. Beirlant et al. (2004), Ch. 8). Figure 3 displays the function $\chi_X(q)$ for Model 2 across a range of different $\alpha$ and $\xi$ values.

**6 Discussion**

The paper studies the extremal properties of copulas $(X_1, X_2) = R(W_1, W_2)$ and determines the tail and residual tail dependence coefficients $\chi_X$ and $\eta_X$, respectively.

In Section 2, where $(W_1, W_2)$ is constrained to the sphere of some norm, classical results on multivariate Pareto copulas are recovered for regularly varying $R$, whereas new structures are obtained for distributions of $R$ with light tails or finite upper endpoint. In particular, for the Gumbel MDA we get a large variety of behaviors for asymptotically independent $(X_1, X_2)$ that strongly depend on the auxiliary function $b$ of $R$ and the shape of the $\nu$-sphere. This extends the results of Wadsworth et al. (2017) who considered only the exponential distribution in this class.

![Figure 3](image-url)
For unconstrained distributions of both $R$ and $W$, Section 3 formalizes the general intuition that heavier tails of $R$ introduce more additional dependence in $(X_1, X_2)$. The results summarized in Table 3 for the special case of the independence model allow for several conclusions. The most interesting (and involved) situations figure along the main diagonal where $R$ and $W$ have similar tail behavior. Above this main diagonal, $R$ is so heavy that it mostly dominates the extremal dependence in $(X_1, X_2)$. On the other hand, below the diagonal, $R$ is too light tailed, relatively to $W$, to have an impact on the tail dependence coefficients $\chi_X$ and $\eta_X$. Similar observations hold true for the more general case of arbitrary dependence in $(W_1, W_2)$ summarized in Table 2.

We note that there is a clear overlap between the results obtained in Sections 2 and 3. If one considers $\chi_W$ as derived from the shape of $W$, then many results in Section 2 are obtained from Section 3, just as Proposition 1 is relevant in both sections. However, the separate treatment seems justified on the grounds of the importance of such constructions, and the additional insight gained in focusing on the shape of $W$.

Multivariate analogs of the upper and residual tail dependence coefficients are obtained by considering the $d$-variate survival function $P(X_1 \geq x_1, \ldots, X_d \geq x_d)$ in Eqs. 2 and 3. For random scale constructions in $d$ dimensions, the results from Section 3 are all directly applicable if the $W_j$ components have common margins, since similarly to the bivariate case, we only need to consider the two variables $X_\wedge = R \min(W_1, \ldots, W_d)$ and $X_j = RW_j$. An assumption of common margins is more realistic in spatial models, where dependence is often analyzed in terms of bivariate margins anyway.

The above results provide a general and unifying framework to analyze bivariate extremal dependence, and Section 4 shows that they cover many of the existing examples in the copula and the extreme value literature. Most importantly, combining the insights from different sections enables the construction of numerous new statistical models that smoothly interpolate between asymptotic dependence and independence; see Section 5 for two instances.

Although our focus was on dependence, knowledge on how the marginal scales of $R$ and $W$ and the dependence properties of $(W_1, W_2)$ influence the dependence of $(X_1, X_2)$ makes it easier to construct models $(X_1, X_2)$ that naturally accommodate both marginal distributions and dependence of multivariate data. Such modeling avoids what may be construed as the artificial separation of modeling of margins and dependence known as copula modeling. For example, in factor constructions based on independent random variables, such as the ones with independent $W_1$ and $W_2$ discussed throughout, our results give guidance on the relative tail heaviness of $R$ with respect to $(W_1, W_2)$ necessary to transition from asymptotic independence to asymptotic dependence in $(X_1, X_2)$, and both heavy- or light-tailed marginal distributions are possible by considering the distribution of either $(X_1, X_2)$ or $\log(X_1, X_2)$ as a model for data.

In Sections 2 and 3, we often considered the simplification $W_1 \overset{d}{=} W_2$, yielding $X_1 \overset{d}{=} X_2$, which allows the coefficients $\chi_X$ and $\eta_X$ to be calculated without reference to marginal quantile functions. A weaker sufficient condition for this is $F_{X_1}(x) \sim$
Extremal dependence of random scale constructions

\[ \overline{F}_{X_2}(x) \] as \( x \to x^* \), with \( x^* \) a common upper end point. To see this sufficiency, define \( x_q = \min\{F_{X_1}^{-1}(q), F_{X_2}^{-1}(q)\} \), \( x^q = \max\{F_{X_1}^{-1}(q), F_{X_2}^{-1}(q)\} \), and note that

\[
\frac{P(X_1 \geq x^q, X_2 \geq x^q)}{\max\{\overline{F}_{X_1}(x^q), \overline{F}_{X_2}(x^q)\}} \leq \frac{P(X_1 \geq F_{X_1}^{-1}(q), X_2 \geq F_{X_2}^{-1}(q))}{1 - q} \leq \frac{P(X_1 \geq x_q, X_2 \geq x_q)}{\min\{\overline{F}_{X_1}(x_q), \overline{F}_{X_2}(x_q)\}},
\]

where \( \max\{\overline{F}_{X_1}(x^q), \overline{F}_{X_2}(x^q)\} = \min\{\overline{F}_{X_1}(x_q), \overline{F}_{X_2}(x_q)\} = 1 - q \). Consequently, the tail dependence coefficient \( \chi_{X} \) of \((X_1, X_2)\), if it exists, is bounded between the limit superior of the left-hand side and the limit inferior of the right-hand side in Eq. 20, respectively, for \( q \to 1 \). Whilst these bounds hold in general for common upper end point, they deliver the precise coefficient \( \chi_{X} \) only if \( F_{X_1}(x) \sim F_{X_2}(x) \), \( x \to x^* \) or both limits are zero. Similar arguments apply to the residual tail dependence coefficient \( \eta_{X} \), where the corresponding bounds determine \( \eta_{X} \) under the weaker requirement \( \log F_{X_1}(x) \sim \log F_{X_2}(x) \), \( x \to x^* \).

Whilst our focus has been on the coefficients \( \chi_{X} \) and \( \eta_{X} \), we note that there are important aspects of the dependence structure that are not described by these coefficients. For example, in Section 2, we found that when \( R \) was in the Gumbel or negative Weibull MDA, \( \chi_{X} \) and \( \eta_{X} \) depended only on the shape of \( \nu \) and the distribution of \( R \), but not at all on the distribution of \( Z \). Nonetheless, the latter plays an important role in the behavior of the slowly varying function \( \ell \) in Eq. 3, which was exemplified in Fig. 2.

7 Proofs

This section contains proofs of propositions from Sections 2, 3 and 5. Proofs of lemmas are deferred to Appendix A. Recall that in the case of common marginal distributions \( F_X \) with upper endpoint \( x^* \), the tail dependence coefficient is \( \chi_{X} = \lim_{x \to x^*} \frac{\overline{F}_{X_2}(x)}{\overline{F}_X(x)} \), whilst the residual tail dependence coefficient is \( \eta_{X} = \lim_{x \to x^*} \frac{\log \overline{F}_X(x)}{\log \overline{F}_{X_2}(x)} \).

7.1 Proofs for Section 2

Proof of Proposition 1 Since \( E(W_j^{\alpha+\varepsilon}) < \infty, j = 1, 2 \), Breiman’s lemma (Breiman (1965), see also Lemma 8 in Appendix A) gives

\[
\overline{F}_{X_j}(x) \sim E(W_j^{\alpha}) \overline{F}_R(x), \quad x \to \infty, \tag{21}
\]

so that \( \overline{F}_{X_j} \in RV^{\infty, \alpha}_\alpha \). Now consider the quantile functions of \( X_j \) and \( R \); denote these by \( F_{X_j}^{-1}(q), F_R^{-1}(q) \). Suppose firstly that \( \alpha > 0 \). Taking the reciprocal of relation (21), and using Proposition 2.6 (vi) of Resnick (2007), we have

\[
F_{X_j}^{-1}(q) \sim F_R^{-1}(q) E(W_j^{\alpha})^{1/\alpha}, \quad q \to 1. \tag{22}
\]
Consider now
\[
P(X_1 \geq F_{X_1}^{-1}(q), X_2 \geq F_{X_2}^{-1}(q))
= P\left(R \min \left\{ \frac{W_1}{E(W_1^\alpha)^{1/\alpha} [1 + o(1)]}, \frac{W_2}{E(W_2^\alpha)^{1/\alpha} [1 + o(1)]} \right\} \geq F_{R}^{-1}(q) \right).
\]

Since \(E(W_{j}^{\alpha+\varepsilon}) < \infty\), \(j = 1, 2\), and \(\min(W_1/E(W_1^\alpha)^{1/\alpha}, W_2/E(W_2^\alpha)^{1/\alpha}) \leq [W_j/E(W_j^\alpha)^{1/\alpha}]^{\alpha+\varepsilon}\) for \(j = 1, 2\) we have \(E[\min(W_1/E(W_1^\alpha)^{1/\alpha}, W_2/E(W_2^\alpha)^{1/\alpha})^{\alpha}] < \infty\). By dominated convergence we therefore also have
\[
E\left(\min \left\{ \frac{W_1}{E(W_1^\alpha)^{1/\alpha} [1 + o(1)]}, \frac{W_2}{E(W_2^\alpha)^{1/\alpha} [1 + o(1)]} \right\}^\alpha\right) 
\rightarrow E[\min(W_1^{\alpha}/E(W_1^\alpha), W_2^{\alpha}/E(W_2^\alpha))],
\]
and so as \(q \rightarrow 1\)
\[
P\left(R \min \left\{ \frac{W_1}{E(W_1^\alpha)^{1/\alpha} [1 + o(1)]}, \frac{W_2}{E(W_2^\alpha)^{1/\alpha} [1 + o(1)]} \right\} \geq F_{R}^{-1}(q) \right)
\sim E\left(\min \left\{ \frac{W_1^\alpha}{E(W_1^\alpha)}, \frac{W_2^\alpha}{E(W_2^\alpha)} \right\} \right)\overline{F}_R(F_{R}^{-1}(q)),
\]
from which the result follows. For \(\alpha = 0\) we have \(\overline{F}_{X_j}(x) \sim \overline{F}_R(x) \in RV_{0}^\infty\), as well as \(\overline{F}_{X_\wedge}(x) \sim \overline{F}_R(x)\). Using the bounds in Eq. 20 and taking limits, we get \(\chi_X = 1\). As noted after the proposition, the conditions ensure \(\chi_X > 0\) and hence \(\eta_X = 1\).

Before proceeding to the proofs of Propositions 2 and 3, Lemma 2 provides detail on the tail behavior of \(W\) and \(W_\wedge\), whilst Lemma 3 is a reformulation of the relevant components of Theorem 3.1 of Hashorva et al. (2010), that will be repeatedly useful.

**Lemma 2** Assume (Z1), (N1) and (N2).

1. If \(b_1 = b_2 = 1\) then \(\overline{F}_W(1 - \cdot) \in RV_{\alpha W}^0\) with \(\alpha W = \alpha Z\gamma\).
2. If \(b_1 < 1\) then
   a) \(\overline{F}_W(1 - \cdot) - P(W = 1) \in RV_{\alpha W}^0\) with \(\alpha W = \gamma\).
   b) In particular, if \(b_1 < 1\), \(\tau_1'(b_{1-}), \tau_2'(b_{2+}) \neq 0\), then \(\overline{F}_W(1 - s) - P(W = 1) = s \ell(s)\), with \(\ell\) satisfying
      \[
      \lim_{s \rightarrow 0} \ell(s) = f_Z(b_1)/\tau_1'(b_{1-}) - f_Z(b_2)/\tau_2'(b_{2+}) \in (0, \infty),
      \]
      where for \(b_2 = 1\) we put \(\tau_2'(b_{2+}) = \infty\). In this case, \(\overline{F}_W(1 - \cdot) - P(W = 1) \in RV_{\alpha W}^0\) with \(\alpha W = \gamma = 1\).
3. $F_{W_\wedge}(\zeta(1-s)) \in RV_1^0$, with slowly varying function $\ell_\wedge$ satisfying
\[
\lim_{s \to 0} \ell_\wedge(s) = 2f_Z(1/2)\zeta/\tau_1'(1/2_\wedge).
\] (25)

**Lemma 3** (Hashorva et al. (2010)) Let $Y = RS$, where $R \in (0, r^*)$, $r^* \in (0, \infty)$, $S \in (0, 1)$ and $F_S(1-s) = \ell(s)s^{\alpha_S}$, $\ell \in RV_0^0$, $\alpha_S > 0$. Then

- If $R$ is in the Gumbel MDA with auxiliary function $b$,
  \[
  F_Y(x) \sim \Gamma(1 + \alpha_S) F_S(1 - (xb(x))^{-1}) F_R(x), \quad x \to r^*. \]  (26)

- If $R$ is in the negative Weibull MDA,
  \[
  F_Y(r^*-s) \sim \frac{\Gamma(1 + \alpha_S)\Gamma(1 + \alpha_R)}{\Gamma(1 + \alpha_S + \alpha_R)} F_S(1-s/r^*) F_R(r^*-s), \quad s \to 0. \]  (27)

**Remark 6** Lemma 3 is easily extended to the case where $S$ has upper endpoint $s^* \in (0, \infty)$, by writing $RS = s^*R \times S/s^*$, and noting that: (i) if $R$ is in the Gumbel MDA, with upper endpoint $r^*$ and auxiliary function $b(t)$, then $s^*R$ is in the Gumbel MDA with upper endpoint $s^*r^*$ and auxiliary function $b(t/s^*)/s^*$; (ii) if $R$ is in the negative Weibull MDA, so is $s^*R$, with $F_{s^*R}(s^*r^*-s) = F_R(r^*-s)/s^*$.

**Proof of Proposition 2** For the marginal tail $F_X$ of $X_1$ and $X_2$, we have
\[
F_X(x) = \int_{[0,1]} F_R(x/v) dF_W(v) = F_R(x)P(W = 1) + \int_{[0,1]} F_R(x/v) dF_W(v),
\]
with $P(W = 1) = P(Z \in I_\nu)$. Letting $S = W|W < 1$, $F_S(1-s) = \ell(s)s^{\alpha_w}$, $s \to 0$, where $\alpha_w$ is given by the relevant part of Lemma 2, and $\ell \in RV_0^0$. By Lemma 3, we have
\[
F_X(x) - F_R(x)P(W = 1) \sim \Gamma(1 + \alpha_w) \frac{\ell((xb(x))^{-1})}{(xb(x))^{\alpha_w}} F_R(x), \quad x \to r^*. \]  (28)

We always have $xb(x) \to \infty$ as $x \to r^*$, (Hashorva et al. 2010; Resnick 1987, Lemma 1.2), hence if $P(W = 1) = 0$, $F_X(x) \to o(F_R(x))$, $x \to r^*$, whilst if $P(W = 1) > 0$, $F_X(x) \sim P(W = 1) F_R(x)$, $x \to r^*$.

For the joint distribution, $F_{X_\wedge}(x) = P(RW_\wedge \geq x)$, with $W_\wedge \in [0, \zeta]$ for $\zeta \in [1/2, 1]$. By Lemma 2, $F_{W_\wedge}(\zeta(1-s)) = \ell_\wedge(s)s$, $s \to 0$, whilst by Lemma 3 and Remark 6,
\[
F_{X_\wedge}(x) \sim \Gamma(2)\ell_\wedge((x/\zeta)b(x/\zeta))^{-1}((x/\zeta)b(x/\zeta))^{-1} F_R(x/\zeta), \quad x \to \zeta r^*. \]

Therefore,
\[
\chi_X = \lim_{x \to r^*} \frac{F_{X_\wedge}(x)}{F_X(x)} = \lim_{x \to r^*} \frac{\Gamma(2)\ell_\wedge((x/\zeta)b(x/\zeta))^{-1}((x/\zeta)b(x/\zeta))^{-1} F_R(x/\zeta)}{F_R(x)P(W = 1) + \Gamma(1 + \alpha_w) \ell((xb(x))^{-1}) (xb(x))^{-\alpha_w} F_R(x)}. \]  (29)
whilst for \( \zeta \, r^* = r^* \), i.e., \( \zeta = 1 \) or \( r^* = \infty \),
\[
\eta_X = \lim_{x \to r^*} \log \frac{F_X(x)}{F_X(r^*)} = \lim_{x \to r^*} \log \frac{[F_R(x)P(W=1) + \Gamma(1+\alpha_W)\ell((xb(x))^{-1}xb(x))^{-\alpha_W}F_R(x)]}{[\Gamma(2)\ell((x/\zeta)b(x/\zeta))^{-1}((x/\zeta)b(x/\zeta))^{-1}F_R(x/\zeta)]} = \lim_{x \to r^*} \log \frac{F_R(x)}{F_R(x/\zeta)}. \tag{30}
\]

The latter equality follows by definition (8) and l’Hôpital’s rule, providing \( \lim_{x \to r^*} \log(xb(x))/\log F_R(x) = 0 \). Now if \( \zeta < 1 \) and \( r^* = \infty \), then \( \chi_X = 0 \) by Eq. 9, with \( \eta_X \) given by Eq. 30. If \( r^* < \infty \), \( X_\wedge \) has upper bound \( \zeta \, r^* < r^* \) and so \( \chi_X = 0 \) also, and \( \eta_X \) is not defined.

If \( \zeta = 1 \) then \( \chi_X = 0 \) if \( P(W=1) > 0 \) by Eq. 29, whilst \( \eta_X = 1 \) by Eq. 30. If \( P(W=1) = 0 \), then \( b_1 = b_2 = 1/2 \), with Lemma 2 giving \( \alpha_W = 1 \) and
\[
\chi_X = \lim_{s \to r^*} \frac{\ell_\wedge((xb(x))^{-1})}{\ell((xb(x))^{-1})} = \frac{2f_Z(1/2)/\tau'_1(1/2_+)}{f_Z(1/2)/\tau'_1(1/2_-) - f_Z(1/2)/\tau'_2(1/2_+)}.
\]

The function \( \tau \) is not differentiable at \( 1/2 \) when \( \zeta = 1 \) so \( \tau'_1(1/2_-) \neq \tau'_2(1/2_+) \) and rearrangement gives the result. \( \square \)

**Proof of Proposition 3** Following a similar line to Proposition 2, the marginal distribution satisfies
\[
\bar{F}_X(r^*-s) - \bar{F}_R(r^*-s)P(W=1) \sim \frac{\Gamma(1+\alpha_W)\Gamma(1+\alpha_R)}{\Gamma(1+\alpha_W+\alpha_R)} \ell(s/r^*) (s/r^*)^\alpha_W \bar{F}_R(r^*-s) \sim \tilde{\ell}(s)s^\alpha_W, \quad s \to 0,
\]

for a new slowly varying function \( \tilde{\ell} \), whilst for the joint distribution
\[
\bar{F}_{X_\wedge}(\zeta \, r^*-s) \sim \frac{\Gamma(2)\Gamma(1+\alpha_R)}{\Gamma(2+\alpha_R)} \ell_\wedge(s/(\zeta \, r^*)) (s/(\zeta \, r^*))^{1+\alpha_R} \bar{F}_R(r^*-s/\zeta) \sim \tilde{\ell}_\wedge(s)s^{1+\alpha_R}, \quad s \to 0.
\]

If \( \zeta < 1 \), then \( X_\wedge \) has upper bound \( \zeta \, r^* < r^* \) and so \( \chi_X = 0 \), with \( \eta_X \) not defined.

If \( \zeta = 1 \) and \( P(W=1) > 0 \), then \( \chi_X = 0 \), and
\[
\eta_X = \lim_{s \to 0} \log \frac{\bar{F}_X(r^*-s)}{\bar{F}_{X_\wedge}(r^*-s)} = \lim_{s \to 0} \log \frac{\bar{F}_R(r^*-s)}{s \bar{F}_R(r^*-s)} = \alpha_R/(1+\alpha_R).
\]

Otherwise, if \( \zeta = 1 \) and \( P(W=1) = 0 \), then since \( \alpha_W = 1 \)
\[
\frac{\bar{F}_{X_\wedge}(r^*-s)}{\bar{F}_X(r^*-s)} \sim \ell_\wedge(s/(r^*)) / \ell(s/(r^*)), \quad s \to 0,
\]

with the behavior of \( \ell \) and \( \ell_\wedge \) as given in Eqs. 24 and 25. \( \square \)

### 7.2 Proofs for Section 3

We often write \( S = \log R \) and \( V = \log W \) and \( V_\wedge = \log W_\wedge \) in the following. We denote the common marginal distribution of \( X_1 \) and \( X_2 \) by \( F_X \). We first recall a result on the convolution with a convolution-equivalent distribution.
Lemma 4 (Convolution with a distribution in CEα, see Theorem 1 of Cline (1986) and Lemma 5.1 of Pakes (2004)) Let $Y_1 \sim F_1$, $Y_2 \sim F_2$ be two random variables. If $F_1 \in \text{CE}_\alpha$ with $\alpha \geq 0$ and $F_2(x)/F_1(x) \rightarrow c \geq 0$, $x \rightarrow \infty$, then

$$F_1 \ast F_2(x)/F_1(x) \rightarrow \mathbb{E}(e^{\alpha Y_2}) + c\mathbb{E}(e^{\alpha Y_1}), \quad x \rightarrow \infty.$$  \hspace{1cm} (31)

Proof of Proposition 4 1. The assumption $F_W(x)/F_R(x) \rightarrow c$, $x \rightarrow \infty$, is equivalent to $F_V(x)/F_S(x) \rightarrow c$. We then apply Eq. 31 and obtain $F_X \sim (1 + c)F_R$. Since $F_{V,\wedge}(x)/F_S(x) \rightarrow \chi_W, x \rightarrow \infty$, we get $F_{X,\wedge}(x) = F_{S,\wedge}((\log x) \sim (1 + c\chi_W)F_S(\log x) = (1 + c\chi_W)F_R(x)$, and the value $\chi_X$ in Eq. 11 follows. Since $\chi_X > 0$ in all cases, we have $\eta_X = 1$.

2. Let $F_V \in \text{CE}_0$ and $F_R = o(F_W)$. Then, $F_S = o(F_V)$, and Eq. 31 gives $F_X \sim F_W$. If $\chi_W > 0$, then $F_S = o(F_{V,\wedge})$, and Eq. 31 yields the tail equivalence $F_{X,\wedge}(x) \sim F_{R,\wedge}(x)$, which entails $\chi_X = \chi_W$. In the case where $\chi_W = 0$, we have $F_{V,\wedge} = o(F_V)$ and $F_S = o(F_V)$, such that Foss et al. (2009, Corollary 5(ii)) establishes $F_{X,\wedge} \sim F_R + F_{W,\wedge} + o(F_W)$, and $\chi_X = \chi_W = 0$ follows.

2.a) When further $F_S, F_{V,\wedge} \in \text{CE}_0$ and $F_R(x)/F_{W,\wedge}(x) \leq C$ with $C > 0$ as $x \rightarrow \infty$, we consider the two boundary cases $F_R = o(F_{W,\wedge})$ and $F_R/F_{W,\wedge} \sim C$. Using Eq. 31, we get

$$\frac{\log F_X(x)}{\log F_{X,\wedge}(x)} \sim \frac{\log F_W(x)}{\log(F_R(x) + F_{W,\wedge}(x))} = \frac{\log F_W(x)}{\log F_{W,\wedge}(x) + \log(1 + F_R(x)/F_{W,\wedge}(x))} \sim \frac{\log F_W(x)}{\log F_{W,\wedge}(x)} \sim \eta_W, \quad x \rightarrow \infty,$$

in both cases, which proves $\eta_X = \eta_W$.

2.b) When further $F_S \in \text{CE}_0$ and $F_{W,\wedge} = o(F_R)$, we get $F_{X,\wedge}(x) \sim F_R(x)$ from Eq. 31, such that

$$\log F_X(x)/\log F_{X,\wedge}(x) \sim \log F_W(x)/\log F_R(x), \quad x \rightarrow \infty,$$

and the limit is $\eta_X$ if it exists. \hfill \Box

Proof of Proposition 5 Since $\mathbb{E}(R^{\alpha_W + \varepsilon}) < \infty$ for a small $\varepsilon > 0$, by Breiman’s lemma, the marginal distributions satisfy

$$F_X(x) \sim \mathbb{E}(R^{\alpha_W})F_W(x), \quad x \rightarrow \infty,$$

so that $X$ is also regularly varying with index $\alpha_W$. The coefficient $\eta_W$ is not defined if $W_\wedge$ has a finite upper endpoint, in which case $\mathbb{E}(W_\wedge^{\alpha_W + \varepsilon}) < \infty$. Otherwise, we have that $W_\wedge$ is regularly varying with index $\alpha_W/\eta_W$, or if $\eta_W = 0$, $F_{W,\wedge}$ decays faster than any power. Again, by Breiman’s lemma (Breiman 1965), we obtain that

$$F_{X,\wedge}(x) \sim \begin{cases} \mathbb{E}(W_\wedge^{\alpha_R})F_R(x), & \text{if } \alpha_R < \alpha_W/\eta_W, \eta_W = 0 \text{ or } \eta_W \text{ not defined}, \\ \mathbb{E}(R^{\alpha_W/\eta_W})F_{W,\wedge}(x), & \text{if } \alpha_R > \alpha_W/\eta_W \text{ or } \alpha_R = +\infty. \end{cases}$$
If $\chi_W > 0$ then $\eta_W = 1$, so we conclude that $\chi_X = \lim_{x \to \infty} \frac{F_{X,\wedge}(x)}{F_X(x)} = \chi_W$. For the coefficient of residual tail dependence between $X_1$ and $X_2$ we obtain

$$
1/\eta_X = \lim_{x \to \infty} \frac{\log F_{X,\wedge}(x)}{\log F_X(x)}
$$

\[=
\begin{cases}
\lim_{x \to \infty} \frac{\log F_R(x)}{\log F_W(x)} = \alpha_R/\alpha_W, & \text{if } \alpha_R < \alpha_W/\eta_W, \\
\lim_{x \to \infty} \log F_{W,\wedge}(x)/\log F_W(x) = 1/\eta_W, & \text{if } \alpha_R > \alpha_W/\eta_W \text{ or } \alpha_R = +\infty.
\end{cases}
\]

Before the proof of Proposition 6, we recall two lemmas from the literature.

**Lemma 5** (Convolution of distributions in $\text{ET}_{\alpha,\beta > -1}$, see Theorem 4(v) of Cline (1986)) For two distributions $F_i \in \text{ET}_{\alpha_i,\beta_i}$, $i = 1, 2$, possessing gamma-type tail $F_i(x) \sim \ell_i(x)x^{\beta_i}\exp(-\alpha x)$, $x \to \infty$ with slowly varying $\ell_i(x)$, we get

$$
F_1 \ast F_2(x) \sim \frac{\Gamma(\beta_1 + 1)\Gamma(\beta_2 + 1)}{\Gamma(\beta_1 + \beta_2 + 2)} \ell_1(x)\ell_2(x)x^{\beta_1 + \beta_2 + 1}\exp(-\alpha x), \quad x \to \infty.
$$

**Lemma 6** (Ratio of convolutions with a distribution in $\text{ET}_{\alpha}$) Let $F \in \text{ET}_{\alpha}$ with $\alpha > 0$, and let $G_1, G_2$ be distributions satisfying $G_2(x)/G_1(x) \to c, \ x \to \infty$, with $c \geq 0$. Given a distribution $H$, we write $M_H(\alpha) = \int \exp(\alpha x)H(dx) \in (0, \infty]$.

1. If $G_1 \in \text{ET}_{\alpha}, c > 0$ and $M_F(\alpha) = M_{G_1}(\alpha) = \infty$, then

$$
F \ast G_2 \sim c \ F \ast G_1, \quad x \to \infty.
$$

2. If $M_{G_1}(\alpha) < \infty$ and $F \ast G_1 \sim M_{G_1}(\alpha)F$, then

$$
F \ast G_2/F \ast G_1 \sim M_{G_2}(\alpha)/M_{G_1}(\alpha), \quad x \to \infty.
$$

**Proof** of Proposition 6

1. To show $\eta_X = 1$, we exploit the closure of $\text{ET}_{\alpha}$ under convolution (Lemma 2.5, Watanabe (2008)); equivalently, $\text{RV}_{\alpha}$ is closed under product convolutions. Applying Resnick (2007, Proposition 2.6(i)) yields

$$
\log F_{S+V}(x)/\log F_S(x) \sim (\alpha x)/(\alpha x) = 1. \quad (32)
$$

It remains to show that the limit in Eq. 32 does not change when we substitute $\log F_{S+V,\wedge}(x)$ for $\log F_S(x)$ in the denominator, where no additional assumption on the distribution of $V_\wedge$ is made. If $p_\wedge^+ = F_{V_\wedge}(0) > 0$, we get $F_{S+V,\wedge}(x) \geq p_\wedge^+ F_S(x)$ for $x > 0$, and then

$$
\log F_{S+V}(x)/\log F_{S+V,\wedge}(x) \geq \log F_{S+V}(x)/(\log F_S(x) + \log p_\wedge^+) \sim 1,
$$

such that $\eta_X = 1$. If $p_\wedge^+ = 0$, then Breiman’s lemma (Breiman 1965) gives $F_{S+V,\wedge} \sim E(W_\wedge^\alpha)F_S$, and $\eta_X = 1$ follows by analogy with Eq. 32.
2. In the case where $F_S \in CE_\alpha$ and $\overline{F}_V(x)/\overline{F}_S(x) \to c \geq 0$, $x \to \infty$, we can use Lemma 4 with $F_1 = F_S$ and $F_2 = F_V$, which yields

$$\frac{\overline{F}_{S+V}(x)}{\overline{F}_S(x)} \sim E\left(e^{\alpha V}\right) + cE\left(e^{\alpha S}\right) = E\left(W^\alpha\right) + cE\left(R^\alpha\right)$$

and by setting $F_2 = F_{V_\lambda}$, we get

$$\frac{\overline{F}_{S+V}(x)}{\overline{F}_S(x)} \sim E\left(e^{\alpha V}\right) + c\chi_W E\left(e^{\alpha S}\right) = E\left(W^\alpha\right) + c\chi_W E\left(R^\alpha\right).$$

Combining these two results yields the value of $\chi_X$.

3. If $F_V \in CE_\alpha$ and $\overline{F}_S(x)/\overline{F}_V(x) \to 0$, $x \to \infty$, we use Lemma 4 with $\alpha = 1$, $\beta = \infty$, and $\epsilon < 1$ to show

$$\frac{\overline{F}_{S+V}(x)}{\overline{F}_V(x)} \sim E\left(W^\alpha\right) = E\left(R^\alpha\right).$$

If $\chi_W > 0$, then $\overline{F}_{V_\lambda}(x)/\overline{F}_V(x) \to 0$, $x \to \infty$. Consider the copula $(V_1^\epsilon, V_2^\epsilon)$ defined as the mixture of $(V_1, V_2)$ and $(V, V)$ with probabilities $(1 - \epsilon)$ and $\epsilon$, respectively, for some $0 < \epsilon < 1$. The marginal distribution of $(V_1^\epsilon, V_2^\epsilon)$ is still $F_V$, and the induced $V_\lambda^\epsilon$ satisfies $\overline{F}_{V_\lambda^\epsilon}(x) = (1 - \epsilon)\overline{F}_{V_\lambda}(x) + \epsilon\overline{F}_V(x)$.

Therefore, $\overline{F}_{V_\lambda^\epsilon}(x)/\overline{F}_V(x) \to \epsilon > 0$ and $\overline{F}_{S+V_\lambda}(x)/\overline{F}_V(x) \to 0$ as $x \to \infty$. Since $V_\lambda^\epsilon$ is stochastically larger than $V_\lambda$, this means that also $Y + V_\lambda^\epsilon$ is stochastically larger than $Y + V_\lambda$ for any random variable $Y$, by a coupling argument. Thus,

$$\chi_X = \lim_{x \to \infty} \frac{\overline{F}_{S+V_\lambda}(x)}{\overline{F}_{S+V}(x)} \leq \lim_{x \to \infty} \frac{\overline{F}_{S+V_\lambda^\epsilon}(x)}{\overline{F}_{S+V}(x)} = \lim_{x \to \infty} \frac{\overline{F}_{V_\lambda^\epsilon}(x)}{\overline{F}_V(x)} = \epsilon,$$

where the last but one equation follows from the former case where $\chi_W > 0$ (with $V_\lambda^\epsilon$ taking the role of $V_\lambda$). Since $\epsilon > 0$ is arbitrary, the result follows.

4.a) We consider the case $\chi_W > 0$ where $\beta_W > -1$ or $\beta_W = -1$ and $E(W^\alpha) = \infty$. We can apply Lemma 6(1), which shows $\chi_X = \chi_W$.

4.b) We consider the case $\chi_W \geq 0$ where $\beta_W < -1$ or $\beta_W = -1 < \beta_R$ and $E(W^\alpha) < \infty$. Then, Theorem 4(iv) of Cline (1986) yields $\overline{F}_{S+V_\lambda}(x)/\overline{F}_S(x) \sim E(W_\lambda^\alpha)/E(W^\alpha)$. Therefore, we can apply Lemma 6(2) with $c = \chi_W$, such that $\chi_X = E(W_\lambda^\alpha)/E(W^\alpha)$.

4.c) Here, $\beta_R, \beta_W > -1$ so $S, V$ are gamma-tailed. Since we assume $E(W_\lambda^{\alpha+\epsilon}) < \infty$, Breiman’s lemma (Breiman 1965) provides $\overline{F}_{S+V_\lambda}(x) \sim E(W_\lambda^\alpha)/\overline{F}_S(x)$, whilst by Lemma 5,

$$\overline{F}_{S+V}(x) \sim \frac{\Gamma(\beta_W + 1)\Gamma(\beta_R + 1)}{\Gamma(\beta_W + \beta_R + 2)} \ell_W(x)\alpha^{\beta_W+1}\ell_S(x),$$

so as $x \to \infty$,

$$\chi_X \sim \frac{E(W_\lambda^\alpha)\Gamma(\beta_R + \beta_W + 2)}{\alpha\Gamma(\beta_W + 1)\Gamma(\beta_R + 1)\ell_W(x)\alpha^{\beta_W+1}} \to 0.$$
Proof of Proposition 7. 1. If \( \chi_W > 0 \), then necessarily \( \alpha_W = \alpha_W^\land \), \( \gamma_W = \gamma_W^\land \) and \( \chi_W = c_W^\land /c_W \) where \( \ell_W \sim c_W \) and \( \ell_W^\land \sim c_W^\land \). Using Asmussen et al. (2017, Theorem 3.1 and Theorem 4.1(iii)), we therefore get \( \chi_X = k_X^\land /k_X \), where \( k \) are the constants made explicit in the cited paper for the sums of the Weibull-tailed random variables \( S + V \) and \( S + V^\land \) respectively. By simplifying the resulting expression of \( \chi_X \), which follows from the equalities \( \alpha_W = \alpha_W^\land \), \( \gamma_W = \gamma_W^\land \), we obtain \( \chi_X = c_W^\land /c_W = \chi_W \).

2. When \( \chi_W = 0 \), Asmussen et al. (2017, Theorem 3.1 and Theorem 4.1(iii)) yield

\[
\frac{c_X x^\gamma_X \exp \left( -\alpha_X x^\beta \right)}{\alpha_X} \sim 1, \quad \gamma_X = \gamma_R + \gamma_W + \beta/2, \quad \alpha_X = \frac{\alpha_R \alpha_W^{\beta/(\beta-1)} + \alpha_W \alpha_R^{\beta/(\beta-1)}}{\left( \alpha_R^{1/(\beta-1)} + \alpha_W^{1/(\beta-1)} \right)^\beta},
\]

with a constant \( c_X > 0 \) that can be made explicit, see Asmussen et al. (2017, Theorem 3.1). Moreover, replacing the symbol \( W \) in Eq. 33 with \( W^\land \) yields the tail approximation of \( \log X^\land = S^\land + V^\land \). Applying Lemma 1 to the random vector \((X_1, X_2)\), we get

\[
\eta_X = \frac{\alpha_X}{\alpha_X^\land} = \frac{\left( \frac{\alpha_R \alpha_W^{\beta/(\beta-1)} + \alpha_W \alpha_R^{\beta/(\beta-1)}}{\left( \alpha_R^{1/(\beta-1)} + \alpha_W^{1/(\beta-1)} \right)^\beta} \right)}{\left( \frac{\alpha_W^{1/(\beta-1)} + \alpha_R^{1/(\beta-1)}}{\alpha_W^\land + \alpha_R^\land} \right)^\beta}
\]

By substituting \( \alpha_W/\alpha_W^\land = \eta_W \), and simplifying, Eq. 14 follows.

If \( \chi_W = 0 \) and \( \eta_W < 1 \), then \( \eta_X < 1 \), implying \( \chi_X = 0 \). If \( \eta_W = 1 \) but \( \chi_W = 0 \), then Lemma 1(1) with the assumption of asymptotically constant slowly varying functions implies \( \gamma_W^\land < \gamma_W \). Combining Eq. 33 and Lemma 1(1), \( \chi_X^\land < \gamma_X \) and \( \chi_X = 0 \) also.

For the proof of Proposition 8, we need the following Lemma.

Lemma 7 (Tail decay of products of Weibull-type variables, see Theorem 2.1(b) of Dębicki et al. (2018)) If two independent random variables \( Y_1 \geq 0 \) and \( Y_2 \geq 0 \) are Weibull-tailed such that

\[
\bar{F}_{Y_j}(x) \sim r_j(x) \exp \left( -\alpha_j x^\beta_j \right), \quad x \to \infty, \quad j = 1, 2,
\]

with \( r_j \in RV_{Y_j}^\infty \). Then, as \( x \to \infty \),

\[
\bar{F}_{Y_1 Y_2}(x) \sim C_0 x^{\beta_1 \beta_2 / (\beta_1 + \beta_2)} r_1 \left( C_1 x^{-\beta_1 / (\beta_1 + \beta_2)} \right) r_2 \left( C_1 x^{-\beta_2 / (\beta_1 + \beta_2)} \right) \exp \left( -C_2 x^{-\beta_1 / (\beta_1 + \beta_2)} \right),
\]
with constants $C_1 = (\alpha_1 \beta_1/(\alpha_2 \beta_2))^{1/(\beta_1 + \beta_2)}$, $C_0 = (2\pi \alpha_2 \beta_2/(\beta_1 + \beta_2))^{1/2} C_1^{\beta_2/2}$ and $C_2 = \alpha_1 C_1^{-\beta_1} + \alpha_2 C_1^{\beta_2}$. For $\beta_1 = \beta_2 = \beta$ this simplifies to

$$F_{Y_1 Y_2}(x) \sim \sqrt{\pi} \left(\alpha_1 \alpha_2 x^\beta\right)^{1/4} r_1 \left((\alpha_2/\alpha_1)^{1/(2\beta)} x^{1/2}\right) r_2 \left((\alpha_1/\alpha_2)^{1/(2\beta)} x^{1/2}\right)$$

$$\times \exp\left(-2\sqrt{\alpha_1 \alpha_2 x^\beta/2}\right).$$

Consequently $F_{Y_1 Y_2}$ is of the form (34) with $r_{12} \in RV_0^\infty$, with $\gamma_{12} = (\beta_1 \beta_2 + 2\gamma_1 \beta_2 + 2\gamma_2 \beta_1)/(2(\beta_1 + \beta_2))$.

**Proof** of Proposition 8

Consider the functions $h_j(x) = \ell_j(x) x^{\gamma_j} \exp(-\alpha_j x^{\beta_j})$ with $\ell_j \in RV_0^\infty$, $j = 1, 2$. One easily shows that

$$h_1(x)/h_2(x) \to 0, \quad x \to \infty,$$

if $\beta_1 > \beta_2$, or if $\beta_1 = \beta_2$ and $\alpha_1 > \alpha_2$, or if $\beta_1 = \beta_2$ and $\alpha_1 = \alpha_2$ and $\gamma_1 < \gamma_2$.

Since $F_{X \lambda}(x)/F_{W}(x) \leq 1$, we always have $\beta_2 \leq \beta_{W \lambda}$; moreover, $\beta_2 = \beta_{W \lambda}$ implies $\alpha_2 \leq \alpha_{W \lambda}$, and $\beta_2 = \beta_{W \lambda}$ implies $\gamma_2 \leq \gamma_{W \lambda}$.

Using Lemma 7 for $X = RW$, we find that $F_X \in WT_{\beta_X}$ with parameters $\beta_X = \beta_R \beta_W/(\beta_R + \beta_W)$, $\alpha_X = \alpha_R C_1^{-\beta_R} + \alpha_W C_1^{\beta_W}$, where $C_1 = (\alpha_R \beta_R/(\alpha_W \beta_W))^{1/(\beta_R + \beta_W)}$,

$$\gamma_X = (\beta_R \beta_W + 2\gamma_R \beta_W + 2\gamma_W \beta_R)/(2(\beta_R + \beta_W)),$$

and slowly varying function $\ell_X > 0$. The same result applies to $X_{\lambda} = RW_{\lambda}$ with constants $\beta_{X_{\lambda}}, \alpha_{X_{\lambda}}, \gamma_{X_{\lambda}},$ and slowly varying $\ell_{X_{\lambda}} > 0$.

1. In this case, it follows from Lemma 7 that also $\beta_{X_{\lambda}} = \beta_X$, $\alpha_{X_{\lambda}} = \alpha_X$, and $\gamma_{X_{\lambda}} = \gamma_X$, and thus

$$\chi_X = \lim_{x \to \infty} \frac{F_{X_{\lambda}}(x)}{F_X(x)} = \lim_{x \to \infty} \frac{\ell_{W_{\lambda}}(x)}{\ell_W(x)} = \chi_W \in [0, 1]$$

(37)

since all other dominating terms of higher order cancel out, and the further results follow straightforwardly.

2. Since $\gamma_{W \lambda} < \gamma_W$, Eq. 36 implies $\gamma_{X_{\lambda}} < \gamma_X$, whilst $\beta_X = \beta_{X_{\lambda}}$ and $\alpha_X = \alpha_{X_{\lambda}}$. Similarly to Eq. 37, we therefore obtain $\chi_X = \lim_{x \to \infty} \{\ell_{X_{\lambda}}(x), \ell_X(x)^{-\gamma_X} = 0 = \chi_W$. On the other hand, we have

$$\eta_X = \lim_{x \to \infty} \frac{\log F_{X_{\lambda}}(x)}{\log F_{X}(x)} = \lim_{x \to \infty} \frac{\alpha_{X_{\lambda}} x^{\beta_{X_{\lambda}}}}{\alpha_X x^{\beta_X}} = 1 = \lim_{x \to \infty} \frac{\alpha_W x^{\beta_W}}{\alpha_{W_{\lambda}} x^{\beta_{W_{\lambda}}}} = \eta_W.$$

3. Since $\beta_{W_{\lambda}} = \beta_W$ and $\alpha_{W_{\lambda}} > \alpha_W$, it follows from Eq. 35 that $\chi_W = 0$, and that $\eta_W = \alpha_W/\alpha_{W_{\lambda}}$. We clearly have that $\beta_X = \beta_{X_{\lambda}}$, and

$$\frac{\alpha_X}{\alpha_{X_{\lambda}}} = \frac{\alpha_R \beta_R}{\alpha_W \beta_W} \frac{1 - \beta_R/(\beta_R + \beta_W)}{1 - \beta_{R_{\lambda}}/(\beta_R + \beta_{W_{\lambda}})} + \alpha_W \frac{\beta_R}{(\alpha_W \beta_W)} \frac{\beta_{W_{\lambda}}/(\beta_R + \beta_{W_{\lambda}})},$$

$$= \left(\frac{\alpha_W}{\alpha_{W_{\lambda}}}ight) \frac{\beta_R}{(\beta_R + \beta_{W_{\lambda}})} \in (0, 1).$$
after some algebra and using that $\beta_{W_\wedge} = \beta_W$. Thus, $\alpha_{X_\wedge} > \alpha_X$, and by Eq. 35 we conclude that $\chi_X = 0$, and further

$$\eta_X = \lim_{x \to \infty} (\alpha_X / \alpha_{X_\wedge}) x^{\beta_X - \beta_{X_\wedge}} = (\alpha_W / \alpha_{W_\wedge})^{\beta_R / (\beta_R + \beta_W)} \neq \eta_W.$$  

4. For the case $\beta_W < \beta_{W_\wedge}$, we also have $\beta_X = \beta_R \beta_W / (\beta_W + \beta_R) < \beta_R \beta_{W_\wedge} / (\beta_{W_\wedge} + \beta_R) = \beta_{X_\wedge}$. It therefore follows from Eq. 35 that $\chi_X = \chi_W = 0$ and $\eta_X = \eta_W = 0$.

Proof of Proposition 9

1. For $w^* = 1$, applying Lemma 3 to compute $F_X(x)$ and $F_{X_\wedge}(x)$ gives

$$\chi_X = \lim_{x \to r^*} \frac{\Gamma(1 + \alpha_{W_\wedge}) \ell_{W_\wedge}((xb_R(x))^{-1})[xb_R(x)]^{-\alpha_{W_\wedge}} F_R(x)}{\Gamma(1 + \alpha_W) \ell_W((xb_R(x))^{-1})[xb_R(x)]^{-\alpha_W} F_W(x)}$$

$$= \lim_{s \to 0} \frac{\Gamma(1 + \alpha_{W_\wedge}) \ell_{W_\wedge}(s)s^{\alpha_{W_\wedge}}}{\Gamma(1 + \alpha_W) \ell_W(s)s^{\alpha_W}} = \chi_W,$$

since $xb_R(x) \to \infty$ for $x \to r^*$, $\alpha_{W_\wedge} \geq \alpha_W$, and if $\chi_W > 0$ then necessarily $\alpha_{W_\wedge} = \alpha_W$. Similarly, $\eta_X = \lim_{x \to r^*} \log F_X(x) / \log F_{X_\wedge}(x) = 1$, since, by l'Hôpital’s rule $\lim_{x \to r^*} \log(xb_R(x))/\log F_R(x) = 0$, and therefore the term $\log F_R(x)$ dominates both the numerator and the denominator. Suitable changes for $w^* \neq 1$ follow from Remark 6 following Lemma 3.

2. We observe that for some $z < w^*$ and $K > 0$,

$$\chi_W = \lim_{x \to w^*} \frac{\tilde{F}_{W_\wedge}(x)}{\tilde{F}_W(x)} = \lim_{x \to w^*} K \exp \left\{ - \int_z^x b_{W_\wedge}(t) \left[ 1 - b_W(t)/b_{W_\wedge}(t) \right] dt \right\}.$$  

If $\chi_W > 0$ then we must have $\lim_{x \to w^*} b_{W_\wedge}(x)/b_W(x) = 1$, since $\int_z^{w^*} b_W(t)dt = \infty$. Therefore, by Lemma 3, if $r^* = 1$,

$$\chi_X = \lim_{x \to w^*} \frac{\ell_R((xb_{W_\wedge}(x))^{-1})[xb_W(x)]^{-\alpha_R} F_{W_\wedge}(x)}{\ell_R((xb_W(x))^{-1})[xb_W(x)]^{-\alpha_R} F_W(x)} = \chi_W.$$  

On the other hand, if $\chi_W = 0$, then $\eta_X = \lim_{x \to w^*} \log \tilde{F}_W(x) / \log \tilde{F}_{W_\wedge}(x) = \eta_W$. The case $r^* \neq 1$ follows as in point 1.

3. The upper endpoint of both $X$ and $X_\wedge$ is $x^* = r^*w^*$. Lemma 3 and Remark 6 yield

$$\tilde{F}_X(x^* - s) \sim \frac{\Gamma(1 + \alpha_R) \Gamma(1 + \alpha_W)}{\Gamma(1 + \alpha_R + \alpha_W)} \tilde{F}_{W}(w^* - s/r^*) \tilde{F}_R(r^* - s/w^*),$$

$$\tilde{F}_{X_\wedge}(x^* - s) \sim \frac{\Gamma(1 + \alpha_R) \Gamma(1 + \alpha_W)}{\Gamma(1 + \alpha_R + \alpha_W)} \ell_R(s) \ell_W(s)(r^*)^{-\alpha_W} (w^*)^{-\alpha_R} s^{\alpha_R + \alpha_W},$$

as $s \to 0$, and similarly for $\tilde{F}_{X_\wedge}(x^* - s)$. Therefore, if $\alpha_{W_\wedge} = \alpha_W$, then

$$\frac{\tilde{F}_{X_\wedge}(x^* - s)}{\tilde{F}_X(x^* - s)} \sim \frac{\tilde{F}_{W_\wedge}(w^* - s)}{\tilde{F}_W(w^* - s)} \sim \frac{\ell_{W_\wedge}(s)}{\ell_W(s)} s^{\alpha_{W_\wedge} - \alpha_W}.$$
and consequently, \( \chi_X = \chi_W \). If \( \alpha_{W^\wedge} > \alpha_W \), then \( \chi_X = \chi_W = 0 \). For the residual tail dependence coefficient we only need to keep the dominating terms, and we compute \( \eta_X = \lim_{s \to 0} \log \frac{F_X(x^* - s)}{\log F_{X^\wedge}(x^* - s)} = (\alpha_W + \alpha_R)/(\alpha_{W^\wedge} + \alpha_R) \).

### 7.3 Proofs for Section 5

**Proof of Proposition 10** For \( \theta > 1 \), the norm \( \nu \) is as in Example 2, and the result for \( \chi_X \) is derived using Proposition 2. For \( \theta < 1 \), \( \nu \) requires rescaling to meet our requirement that \( \nu(x, y) \geq \max(x, y) \) with equality somewhere. Note that scaling by any constant \( K \in (0, \infty) \) does not affect the dependence, i.e., \( (X_1, X_2) = R(\tau(Z), \tau(1 - Z)) \) has the same copula as \( (X_1, X_2) = R(\tau(Z), \tau(1 - Z))/K \).

For \( \theta \in [1/2, 1] \) we therefore define \( \nu^*(x, y) = \theta^{-1}\nu(x, y) \) which satisfies the required scaling, so that \( \zeta = 1/\nu^*(1, 1) = \theta \). The result for \( \eta_X \) is then also given by Proposition 2.

**Proof of Proposition 11** The first claim follows directly from Proposition 1, since \( E(W_1^{1/\xi + \epsilon}) < \infty \). Since \( \eta_W \in (0, 1) \) is defined, \( W^\wedge \) has the same upper endpoint as \( W \), and \( \bar{F}_{W^\wedge}(w^* - s) = \ell_{W^\wedge}(\bar{F}_W(s))\bar{F}_W(s)^{1/\eta_W} \), implying \( W^\wedge \) is also in the negative Weibull MDA with \( \alpha_{W^\wedge} = \alpha_W/\eta_W \). The second and third claims then follow from parts 1 and 3 of Proposition 9.

### Appendix A: Lemmas and proofs

#### A.1 Additional lemmas

The following Lemma 8 is widely known as *Breiman’s lemma* and is useful in several contexts throughout Section 7.

**Lemma 8** (Breiman’s lemma, see Breiman (1965), Cline and Samorodnitsky (1994), and Pakes (2004), Lemma 2.1) Suppose \( X \sim F, Y \sim G \) are independent random variables. If \( F \in RV^\infty_\alpha \) with \( \alpha \geq 0 \) and \( Y \geq 0 \) with \( E(Y^{\alpha + \epsilon}) < \infty \) for some \( \epsilon > 0 \), then

\[
\bar{F}_{XY}(x) \sim E(Y^\alpha) \bar{F}(x), \quad x \to \infty.
\]

Equivalently, if \( F \in ET_\alpha \) and \( E(e^{(\alpha + \epsilon)Y}) < \infty \), then \( \bar{F}_{X+Y}(x) = \bar{F} \ast G(x) \sim E(e^{\alpha Y}) \bar{F}(x) \).
The following Lemma 9 provides some additional detail on the function \( \tau \), as defined in Section 2.

**Lemma 9** If \( 1 - \tau_1(b_1 - \cdot) \in RV_{1/\gamma_1}^0 \), for \( \gamma_1 > 0 \), then \( b_1 - \tau_1^{-1}(1 - \cdot) \in RV_{1/\gamma_1}^0 \), and \( \gamma_1 \leq 1 \). Similarly, if \( 1 - \tau_2(b_2 + \cdot) \in RV_{1/\gamma_2}^0 \), for \( \gamma_2 > 0 \), then \( \tau_2^{-1}(1 - \cdot) - b_2 \in RV_{\gamma_2}^0 \) and \( \gamma_2 \leq 1 \).

**Proof** The argument is similar for both cases, so we focus on the first one. Let \( g(t) = 1 - \tau_1(b_1 - t) \), which is decreasing as \( t \to 0 \) and invertible, with \( g^{-1}(s) = b_1 - \tau_1^{-1}(1 - s) \). Since \( g \in RV_{1/\gamma_1}^0 \), then \( g^{-1} \in RV_{\gamma_1}^0 \) (Resnick (2007), Proposition 2.6(v), adapting to regular variation at zero). Now make the left-sided Taylor expansion

\[
\tau_1(b_1 - t) = \tau_1(b_1) - \tau_1'(b_1-) + O(t^2),
\]

and note that \( \tau_1(b_1) = 1 \). Consequently, \( 1 - \tau_1(b_1 - t) = \tau_1'(b_1-) + O(t^2) \), and so finiteness of \( \tau_1'(b_1-) \) will imply that the index of regular variation of \( g \) is at least 1. Define the convex function \( \mu : (0, \infty) \to (0, \infty) \) by \( \mu(x) = v(1, x) \), so that \( \tau(x) = 1/\mu(1/x - 1) \). Since \( \tau_1 \) is increasing on \((0, b_1), \mu \) is increasing on \((1 - b_1)/b_1, \infty) \). We have

\[
\tau'(x-) = x^{-2} \mu'((1/x - 1)_+)/\mu(1/x - 1)^2,
\]

and so \( \tau_1'(b_1-) = b_1^{-2} \mu'((1-b_1)/b_1)_+)/\mu((1-b_1)/b_1)^2 \). For \( h \in (0, 1) \), convexity entails

\[
\mu((1-b_1)/b_1 + h) \leq h \mu((1-b_1)/b_1) + (1 - h) \mu((1-b_1)/b_1),
\]

and so

\[
0 \leq \frac{\mu((1-b_1)/b_1 + h) - \mu((1-b_1)/b_1)}{h} \leq \mu((1-b_1)/b_1 + 1) - \mu((1-b_1)/b_1) < \infty.
\]

Hence \( \mu'((1-b_1)/b_1)_+) < \infty \), giving \( \tau_1'(b_1-) < \infty \). Thus the index of regular variation of \( g \) is at least 1.

The following Lemma 10 clarifies the influence of negative values in convolutions of exponential-tailed distributions. It allows us to extend certain results from the literature formulated for nonnegative random variables to the real line.

**Lemma 10** (Convolutions of exponential-tailed distributions with negative values)

For \( i = 1, 2 \) and probability distributions \( F_i \in ET_\alpha \) defined over \( \mathbb{R} \) with \( \alpha > 0 \), denote \( p_i = \overline{F}_i(0) \in [0, 1] \) the probability of nonnegative values. Using the convention \( 0/0 = 0 \), let \( F_i^+(x) = \overline{F}_i(x)/p_i, x \geq 0 \), denote the conditional distribution of \( F_i \) over nonnegative values, and let \( F_i^- (x) = F_i(x)/(1 - p_i), x < 0 \), denote the conditional distribution of \( F_i \) over negative values. We use the notation \( M_H(\alpha) = \int_{-\infty}^{\infty} \exp(\alpha y)H(dy) \) for a given distribution \( H \). Then:

1. If \( F_i^+(x)/F_1^+ \ast F_2^+(x) \to 0 \) when \( x \to \infty \) for \( i = 1, 2 \), then

\[
F_1 \ast F_2 \sim p_1p_2F_1^+ \ast F_2^+.
\]

(38)
2. If \( F_1^+ \ast F_2^+ \sim c_1 F_1^+ + c_2 F_2^+ \) with constants \( 0 \leq c_1, c_2 < \infty \), then
\[
F_1 \ast F_2(x) \sim F_1(x) \left( p_2 c_1 + (1 - p_2)M_{F_2}^{-}(\alpha) \right) + F_2(x) \left( p_1 c_2 + (1 - p_1)M_{F_1}^{-}(\alpha) \right).
\]

Specifically, if \( c_1 = M_{F_2}^{-}(\alpha) \) and \( c_2 = M_{F_1}^{-}(\alpha) \), then
\[
F_1 \ast F_2(x) \sim M_{F_2}(\alpha) F_1(x) + M_{F_1}(\alpha) F_2(x),
\]
and if \( c_1 = M_{F_2}^{-}(\alpha) \) and \( c_2 = 0 \), then
\[
F_1 \ast F_2(x) \sim M_{F_2}^{-}(\alpha) F_1(x) + F_2(x) (1 - p_1) m_{F_1}(\alpha).
\]

Proof. We start with the mixture representation
\[
F_1 \ast F_2(x) = p_1 p_2 F_1^+ \ast F_2^+ + p_1(1 - p_2) F_1^+ \ast F_2^{-} + (1 - p_1) p_2 F_1^{-} \ast F_2^+ , \quad x \geq 0.
\]

We can then use the equation \( p_i F_i^+(x) = F_i(x), \quad x \geq 0 \), and the following inequalities for \( \{i_1, i_2\} = \{1, 2\} \),
\[
0 = F_{i_1}^{-} \ast F_{i_2}^{-} = F_{i_1}^{-}(x) \leq F_{i_1}^+ \ast F_{i_2}^{-}(x) \leq F_{i_1}^+(x) \leq F_{i_1}^+ \ast F_{i_2}^+(x), \quad x \geq 0.
\]

Moreover, Lemma 8 can be applied for mixed terms, yielding \( F_{i_2}^-(\alpha) F_{i_1}^+ \sim M_{F_{i_2}}^{-}(\alpha) F_{i_1}^+ \), and then Eqs. 38 and 39 follow from straightforward calculations. To determine the behavior for special cases of \( c_1 \) and \( c_2 \), observe that \( (1 - p_i) M_{F_i}^{-}(\alpha) + p_i M_{F_i}^+(\alpha) = M_{F_i}(\alpha) \).

\( \square \)

A.2 Proof of lemmas in Section 7

Proof of Lemma 2. 1. If \( b_1 = b_2 = 1 \) then \( P(W = 1) = 0 \) and \( \overline{F}_W(1 - s) = \overline{F}_Z(\tau^{-1}(1 - s)) \). By assumption, \( \overline{F}_Z(\tau^{-1}(1 - s)) = \ell_Z(1 - \tau^{-1}(1 - s))(1 - \tau^{-1}(1 - s))^\alpha_Z \), where \( \ell_Z \in RV_0^\alpha \). Since \( 1 - \tau^{-1}(1 - s) \in RV_0^\gamma \) (Lemma 9) with limit zero, results on composition of regularly varying functions (Resnick (2007), Proposition 2.6 (iv)) implies the result, with \( \alpha_w = \alpha_Z \gamma \).

2.a) If \( b_1 < 1 \) then
\[
\overline{F}_W(1 - s) - P(W = 1) = P(Z \in [\tau_1^{-1}(1 - s), b_1)) + P(Z \in (b_2, \tau_2^{-1}(1 - s))],
\]
and since \( Z \) has a Lebesgue density,
\[
P(Z \in [\tau_1^{-1}(1 - s), b_1)) + P(Z \in (b_2, \tau_2^{-1}(1 - s))]
\sim f_Z(b_1)(b_1 - \tau_1^{-1}(1 - s)) + f_Z(b_2)(\tau_2^{-1}(1 - s) - b_2) \in RV_0^\gamma,
\]
again using Lemma 9.

2.b) A left-sided Taylor expansion of \( \tau_1^{-1} \) about 1 gives
\[
\tau_1^{-1}(1 - s) = b_1 - (\tau_1^{-1})'(1_\gamma s + O(s^2),
\]
where $O(s^2)/s$ uniformly tends to 0 as $s \to 0$, and similarly we can make a right-sided expansion for $\tau^{-1}_2(1-s)$. Hence, using Eqs. 40 and 41, 
$$
\overline{F}_W(1-s) - P(W = 1) = s\ell(s) \text{ with } \lim_{s \to 0} \ell(s) = f_Z(b_1)(\tau^{-1}_1)'(1-) - f_Z(b_2)(\tau^{-1}_2)'(1-) .
$$
Noting the link $1/\tau_1'(b_1) = (\tau^{-1}_1)'(\zeta_1)$, similarly for $1/\tau_2'(b_2)$, gives Eq. 24.

2. For the final part, we have
$$
\overline{F}_W (\zeta(1-s)) = \overline{F}_Z(\tau^{-1}_1(\zeta(1-s))) - \overline{F}_Z(1-\tau^{-1}_1(\zeta(1-s))) \\
\sim f_Z(1/2) \left\{ 1 - 2\tau^{-1}(\zeta(1-s)) \right\}.
$$
Again by left-sided Taylor expansion of $\tau^{-1}_1$ about $\zeta = \tau(1/2)$, we have
$$
\tau^{-1}_1(\zeta(1-s)) = 1/2 - (\tau^{-1}_1)'(\zeta)\zeta s + O(s^2),
$$
and so we obtain 
$$
\overline{F}_Z(\tau^{-1}_1(\zeta(1-s))) - \overline{F}_Z(1-\tau^{-1}_1(\zeta(1-s))) = s\ell_\zeta(s) \text{ with } \lim_{s \to 0} \ell_\zeta(s) = 2f_Z(1/2)\zeta(\tau^{-1}_1)'(\zeta) .
$$
Noting again that $1/\tau_1'(1/2) = (\tau^{-1}_1)'(\zeta)$, we arrive at Eq. 25.

**Proof of Lemma 5** The result for nonnegative $S$ and $V$ is found in Theorem 4(v) of Cline (1986). The extension to negative values then follows from Lemma 10(1).

**Proof of Lemma 6** The result is given in Theorem 6(ii,iii) of Cline (1986) for $\overline{F}(0) = 1$ and $\overline{G}_1(0) = 1$. For point 1, the extension to negative values in $F$ and $G_1$ follows from observing that Theorem 6(iii) of Cline (1986) implies

$$
\overline{F} \star \overline{G}_1 \sim \overline{F^+} \star \overline{G^+_1}, \quad x \to \infty ,
$$

where $F^+$ is obtained from $F$ by setting $F^+(0) = F(0)$ and $\overline{F^+}(0) = 1$, and the same construction is taken for $G^+_1$; i.e., $F^+$ and $G^+_1$ arise from projecting negative values to 0. For point 2, the extension to negative values can be shown using Lemma 10(2). Indeed, the same limit $M_{G_1}(\alpha)$ arises for $\overline{F} \star \overline{G}_1(x)/\overline{F}(x)$ if we project negative values in $F$ and $G_1$ to 0 or not.

**Appendix B: Tail classes and examples**

Definitions of tail classes are given in Section 1.1. The following lemma summarizes important relationships between such tail classes. In this section, we refer to the class of heavy-tailed distributions by HT, and to superheavy-tailed distributions by SHT.

**Lemma 11** (Relationships between tail classes) The following relationships between distribution classes hold:

1. $RV_\alpha^\infty \subset CE_0$ for $\alpha > 0$,
2. $ET_0 \subset HT$.
3. For $ET_\alpha$ with $\alpha > 0$, we have:
   - $F(\exp(\cdot)) \in ET_\alpha \iff F \in RV_\alpha^\infty$,
| Distribution Family | RV$_\alpha^0$ | WT$_\beta$ | ET$_\alpha$ | HT | LWT$_\beta$ | RV$_\alpha^\infty$ |
|---------------------|----------------|------------|-------------|----|-------------|------------------|
| Normal              |                | $\beta = 2$ |             |    |             |                  |
| Log-normal          |                | $\beta = 2$ |             |    |             |                  |
| Exponential         | $\beta = 1$   | $\alpha = \text{scl}$ |           |    |             |                  |
| Gamma               | $\beta = 1$   | $\alpha = \text{scl}$ |           |    |             |                  |
| Inverse normal      | $\beta = 1$   | $\alpha = \frac{\text{shp}}{2 \text{mean}}$ |           |    |             |                  |
| Logistic            | $\beta = 1$   | $\alpha = \text{scl}$ |           |    |             |                  |
| Log-logistic        | $\beta = 1$   |             | $\alpha = \text{scl}$ |    |             |                  |
| Gumbel              | $\beta = 1$   | $\alpha = \text{scl}$ |           |    |             |                  |
| Weibull             | $\beta = \text{shp}$ | $\text{shp} = 1, \alpha = \text{scl}$ | $\text{shp} < 1$ |    |             |                  |
| t                   | $\beta = 1$   | $\alpha = \text{scl}$ |           |    |             |                  |
| Pareto              | $\beta = 1$   | $\alpha = \text{scl}$ |           |    |             |                  |
| Fréchet             | $\beta = 1$   | $\alpha = \text{scl}$ |           |    |             |                  |
| stable              | $\beta = \text{shp} = 2$ | $\text{shp} < 2$ | $\text{shp} < 2, \beta = 1$ | $\alpha = 1/\text{shp} > 1/2$ |                  |
| F(shp1, shp2)       | $\beta = 1$   | $\alpha = \text{scl}$ |           |    |             |                  |
| uniform             | $\alpha = 1$  |             |             |    |             |                  |
| Beta(shp1, shp2)    | $\alpha = \text{shp2}$ |             |             |    |             |                  |
| triangular          | $\alpha = 2$  |             |             |    |             |                  |
| GEV                 | $\alpha = 1/\text{shp} < 0$ | $\text{shp} = 0, \beta = 1$ | $\text{shp} = 0, \alpha = \text{scl}$ | $\text{shp} > 0$ | $\text{shp} > 0, \beta = 1$ | $\alpha = 1/\text{shp}$ |

The column RV$_\alpha^0$ refers to the behavior of $\overline{F}(x^* - \cdot)$ when $x^* < \infty$. All heavy-tailed distributions in this table are also subexponential. All distributions in ET$_\alpha$ listed in this table are in ET$_{\alpha, \beta}$ except for the inverse normal; the inverse normal is in CE$_\alpha$. The parameter shp of the stable distributions is here chosen as their stability parameter.
• $CE_{\alpha} \subset ET_{\alpha}$,  
• $ET_{\alpha, \beta > -1} \cap CE = \emptyset$.

4. For $WT_{\beta}$, we have:
• $WT_{1} \subset \bigcup_{\alpha > 0} ET_{\alpha}$,
• $WT_{\beta} \subset CE_{0}$ for $\beta < 1$,
• $LWT_{\beta} \subset SHT$ for $\beta < 1$.

5. By denoting $F_{1} < F_{2}$ if $\frac{F_{1}(x)}{F_{2}(x)} \to 0$ for $x \to \infty$, we have:
• If $\tilde{\alpha} < \alpha$, then $WT_{\beta > 1} < ET_{\alpha} < ET_{\tilde{\alpha}} < WT_{\beta < 1} < LWT_{\beta > 1} < RV_{\alpha > 0}^{\infty} < RV_{\alpha}^{\infty} < SHT$.
• $CE_{\alpha > 0} < ET_{\tilde{\alpha}, \beta}$ for $\tilde{\alpha} \leq \alpha$ and any $\beta > 0$.

We recall the membership in tail classes for well-known parametric distribution families in Table 4, see Johnson et al. (1994, 1995) for reference about parameters. Here we abstract away from the usual parameter symbols of these distributions to avoid conflicting notations with general tail parameters. We refer parameters as scl and loc if scl $\times X$ + loc has scale scl and location loc, where X has scale 1 and location 0. Another parameter shp may be related to shape for some distributions.

**Appendix C: Additional illustrations**

Figure 4 illustrates further examples of norms $\nu$ and related functions $\tau(z)$ and $\tau(1-z)$, as defined in Section 2.
