ABSTRACT

Anthracyclines are key components of human breast cancer chemotherapy. Here, we explored the role of Akt signaling in anthracycline resistance.

The antitumor activity of doxorubicin and Akt inhibitor A-443654 alone or combined was examined in estrogen receptor (ER) positive and negative human breast cancer cell lines. Further, we examined mRNA changes induced by anthracyclines in locally advanced breast cancers biopsied before and after treatment in two clinical trials.

Doxorubicin increased Akt phosphorylation in ER positive MCF7 and T47D cell lines, with no effect in ER negative MDA-MB231 breast cancer cells. A-443654 was significantly more cytotoxic in doxorubicin-resistant compared to doxorubicin-naïve MCF7. This difference was not observed in MDA-MB231. Among 24 patients, AKT1 gene expression increased 24 hrs after the initial epirubicin exposure in ER positive tumors responding to therapy (n=6), as compared to ER positive non-responders (n=7) or ER negative tumors (n=11). In contrast, AKT1 mRNA changes after 16 weeks of doxorubicin were unrelated to clinical response and ER status (n=30).

In conclusion, rapid Akt activation was observed in ER positive breast cancers which responded to anthracyclines. Increased cytotoxicity of A-443654 in doxorubicin-resistant MCF7 cells indicates a possible role for Akt inhibitors in ER positive breast cancers where chemoresistance evolves.

INTRODUCTION

Phosphatidylinositol-4,5-bisphosphate 3-kinase (PI3K)-Akt-mammalian target of rapamycin (mTOR)-S6 kinase (S6K) signaling (in short: PI3K signaling) is upregulated in 25% of human breast cancers and has been associated with resistance to endocrine as well as HER2 directed therapy [1–3]. PIK3CA, encoding the p110α subunit of PI3K, harbors activating mutations in up to 45% of luminal A breast cancers [4], which are typically estrogen receptor (ER) positive tumors. Thus, therapeutic inhibition of the PI3K signaling pathway with the mTOR inhibitor everolimus can be used to counteract acquired resistance to aromatase inhibitors and prolong survival among patients with ER positive breast cancer [3]. Moreover, activating PIK3CA mutations are observed in ER negative breast cancer as well [4], and mTOR inhibition, combined with trastuzumab and paclitaxel, prolonged progression-free survival significantly among patients with hormone receptor negative, HER2 positive breast cancer [5]. However, the potential to treat chemoresistant breast cancer by inhibiting PI3K signaling has not been thoroughly addressed thus far.

Phosphatase and tensin homolog (PTEN) is the main endogenous inhibitor of PI3K activation [6]. While experimental studies revealed loss of PTEN function to be associated with reduced sensitivity to doxorubicin in breast and prostate cancer models, chemosensitivity was restored by concomitant mTOR inhibition [7, 8]. Furthermore, increased Akt phosphorylation is observed in doxorubicin-resistant ER positive, but not in ER negative breast cancer cell lines [9–11]. In line with this, inhibitors of the PI3K-Akt-mTOR pathway can be employed to
enhance anthracycline sensitivity in ER positive breast cancers [10, 11]. Whereas the introduction of Akt inhibitors in clinical trials has been slower than PI3K and mTOR inhibitors [12], the key position of Akt as a signal hub for important pro-tumorigenic pathways [6] makes such trials highly relevant.

In the present work we assessed the influence of doxorubicin treatment on PTEN and Akt-mTOR-S6K signaling, and the interaction between doxorubicin and the Akt inhibitor A-443654 in ER positive and negative human breast cancer cell lines in vitro and in vivo. In particular, cell lines made resistant to doxorubicin by continuous drug exposure were compared with doxorubicin-naïve cells to decipher the role of Akt-mTOR-S6K signaling in breast cancer chemoresistance. Furthermore, the short-term and long-term changes in PTEN and AKT1 gene expression subsequent to anthracycline exposure were assessed in patients with locally advanced breast cancers.

RESULTS

Influence of doxorubicin treatment on Akt activity and PI3K signaling in doxorubicin-naïve breast cancer cell lines

A sublethal concentration of doxorubicin (24 hrs exposure) was established by the WST-1 assay, to facilitate subsequent assessment of increased cytotoxicity when the A-443654 Akt inhibitor was introduced. The IC30 was approximately 1.5-2.0 μM for MB231 and MCF7 and 0.5-1.0 μM for T47D (Supplementary Figure 1A). Based on this, doxorubicin was used at a concentration of 1.5 μM for MB231, 2 μM for MCF7 and 0.7 μM for T47D for the in vitro experiments. Each experimental setup was conducted in three parallel cell cultures.

Doxorubicin increased phosphorylated Akt (p-Akt) in the ER positive MCF7 and T47D human breast cancer cell lines (Figure 1B, Supplementary Figure 1B). In contrast, p-Akt was not influenced by doxorubicin in the ER negative MB231 cell line (Figure 1A). Whereas doxorubicin had no impact on PTEN protein levels in neither cell line, mTOR phosphorylation levels increased in MB231 and decreased in MCF7 cells (Figure 1A-1B), although not significant by densitometry (Figure 1E-1F). Phosphorylated S6K was weakly expressed in both cell lines, and a non-significant decrease in S6K phosphorylation levels was observed in the MCF7 cell line after doxorubicin exposure (Figure 1A-1B).

AKT1 mRNA levels as determined by qPCR analysis remained unaltered 24 hours after doxorubicin exposure in all three cell lines (Supplementary Figure 2A). While PTEN mRNA levels decreased in MB231 cells, no change was observed in MCF7 and T47D cells subsequent to doxorubicin treatment (Supplementary Figure 2A). The reason why decreased PTEN mRNA levels did not translate into decreased PTEN protein levels in MB231 cells exposed to doxorubicin remains to be elucidated, but the rapid changes in gene expression induced by the chemotherapy could take longer to translate into a change in protein levels, due to a half-life of more than 8 hrs for PTEN [13]. Furthermore, there is no strong correlation between PTEN mRNA and PTEN protein levels in human breast cancer, which could be explained by post-transcriptional and post-translational mechanisms modifying protein expression and stability [14].

Influence of doxorubicin treatment on Akt activity and PI3K signaling in doxorubicin-resistant cell lines

We performed the same experiments as outlined above in MB231 and MCF7 cells made resistant to doxorubicin through long-term doxorubicin exposure (see Methods & materials).

While doxorubicin exposure for 24 hours increased AKT1 gene expression in doxorubicin-resistant MCF7 cells, no significant change in AKT1 expression was observed subsequent to doxorubicin expression in MB231 cells (Supplementary Figure 2B). Notably, PTEN gene expression was profoundly reduced 24 hrs after doxorubicin exposure in doxorubicin-resistant MB231, whereas a minor PTEN increase was observed in doxorubicin-resistant MCF7 cells (Supplementary Figure 2B). While p-Akt increased at the protein level in doxorubicin-resistant compared to doxorubicin-naïve MCF7 cells, no change in downstream signaling was observed. The level of p-Akt was increased in doxorubicin-resistant MB231 cells, compared to doxorubicin-naïve cells, but without any changes in downstream signaling (Figure 1A, 1C). In doxorubicin-resistant MCF7 cells, the protein levels of PTEN, p-Akt, mTOR and p-mTOR were higher compared to doxorubicin-naïve cells (Figure 1B, 1D). However, an additional pulse of doxorubicin treatment did not change PTEN or Akt-mTOR-S6K protein levels further in doxorubicin-resistant MB231 or MCF7 cells, compared to sham treatment (Figure 1C-D).

Akt inhibition in doxorubicin-naïve and resistant MB231 and MCF7 cell lines

Next, we examined the cytotoxicity of the Akt inhibitor A-443654, alone or combined with doxorubicin, in the ER negative MB231 and ER positive MCF7 cell lines. Moreover, based on the increased Akt phosphorylation levels observed in the doxorubicin-resistant cell lines, we compared the doxorubicin-naïve and resistant cell lines with respect to Akt inhibitor cytotoxicity.

First, it was established that the IC30 concentration of A-443654 was 1.0 μM in MB231 and 0.5 μM in the MCF7 cell line (Supplementary Figure 2C). A-443654 is a known ATP competitive inhibitor of Akt, which causes a transient increase in Akt phosphorylation at S473 [15].
In line with this, 2 hrs exposure to A-443654 increased Akt phosphorylation in a dose-dependent manner in MCF7 as well as MB231 cells (Figure 2A-2B). The induction of Akt by A-443654 in ER negative MB231 cells was not influenced by doxorubicin resistance (Figure 2A). However, in ER positive MCF7 cells, the induction of Akt phosphorylation by A-443654 was significantly less prominent in doxorubicin-resistant compared to doxorubicin-naïve cells (Figure 2B), suggesting that long-term doxorubicin exposure exhausts the ability to activate Akt and could influence the response to A-443654. Of notice, the baseline phosphorylation level of Akt in doxorubicin-naïve MB231 differed in Figure 1A and 2A, possibly due to the use of different dissolvents given to control cells in the two experiments; HPMC was used as solvent

Figure 1: Doxorubicin treatment of doxorubicin-naïve and doxorubicin-resistant human breast cancer cell lines. (A-B) Western blots of PTEN and Akt-mTOR-S6K signaling in MB231 and MCF7 breast cancer cells in vitro, either doxorubicin-naïve (A-B) or doxorubicin-resistant (C-D, dox-res). Drug exposure lasted 24 hrs, at either 1.5 μM for MB231 and 2 μM for MCF7 or an equivalent volume of DMSO (stock solvent for doxorubicin) for control wells, three independent experiments per group. Whole cell lysate, 30 μg protein loaded per lane. (E-F) Densitometries for western blots (A-D) depict the relative protein expression, normalized to actin. Phosphorylated Akt (p-Akt) and mTOR (p-mTOR) were normalized to actin and thereafter to total Akt and mTOR, respectively. Bars represent the mean protein expression for experiments performed in triplicate ± SEM. **p<0.01
Figure 2: Akt inhibitor treatment of doxorubicin-naive and doxorubicin-resistant human breast cancer cell lines. (A-B) Western blots of Akt phosphorylation induced by increasing doses of the Akt inhibitor A-443654, 0-10 μM, 2 hrs exposure in doxorubicin-naive or doxorubicin-resistant MB231 (A) and MCF7 (B) human breast cancer cells in vitro. Whole cell lysate, 30 μg protein loaded per lane. Densitometries for western blots (A-B) depict the relative protein expression, normalized to actin and total Akt. Phosphorylated Akt increased significantly in doxorubicin-naive (dox-naive), compared to doxorubicin-resistant MCF7 cells (dox-res), at AKTi concentrations above 0.5 μM. *p<0.05. (C-D) Western blot analysis of Akt and downstream signaling in doxorubicin-naive or doxorubicin-resistant MB231 (C) and MCF7 (D) human breast cancer cells, after 24 hrs exposure to A-443654 (MB231: 1 μM, MCF7 0.5 μM) in vitro. Densitometries for western blots (C-D) depict the relative protein expression, normalized to actin. Bars represent the mean protein expression in experiments performed in triplicate ± SEM.
for A-443654 (Figure 2A), whereas DMSO was the
dissolvent for doxorubicin (Figure 1A).

To decipher the consequence of Akt inhibition in a
wider time frame, Akt phosphorylation and downstream
signaling was assessed after 24 hrs of A-443654 (IC30)
exposure (Figure 2C-2D). As compared to 2 hrs, total
Akt was profoundly reduced after 24 hrs, suggesting the
Akt inhibitor may induce protein degradation. In parallel,
phosphorylated Akt remained upregulated after 24 hrs
of doxorubicin exposure in the doxorubicin-naive as well as
the doxorubicin-resistant MCF7 and MB231 cell
lines, which is in accordance with the reported activity
of A-443654 [16]. With respect to downstream signaling,
it was clearly reduced by A-443654 in the doxorubicin-
naive MCF7 cell line, with decreased GSK3 and S6K
phosphorylation and increased 4EBP1 protein levels
(Figure 2D), and the same signaling inhibition was
observed in the doxorubicin-resistant MB231 cell line.
The influence of A-443654 on Akt downstream signaling
was less pronounced in the MB231 cell line (Figure
2C). Whereas reduced GSK3 and increased 4EBP1
phosphorylation was observed in doxorubicin-naive
MB231, Akt inhibition had no influence on phosphorylated
S6K. In doxorubicin-resistant MB231, A-443654 reduced
S6K and increased 4EBP1 phosphorylation, in accordance
with protein synthesis inhibition, but at the same time
phosphorylated GSK3 protein levels increased, indicating
glycogen synthase and cell cycle activation. All in all,
these results point to a stronger dependence on Akt
downstream signaling for cell proliferation in MCF7 than
in MB231 breast cancer cells when doxorubicin resistance
evolves.

Indeed, the Akt inhibitor exhibited significantly
increased cytotoxicity in doxorubicin-resistant compared to
doxorubicin-naive MCF7 cells (Figure 3B). In contrast,
the cytotoxicity of A-443654 was significantly reduced in
doxorubicin-resistant compared to doxorubicin-naive
MB231 cells (Figure 3A). The cytotoxicity of A-443654
was not augmented by doxorubicin in neither cell line
(Figure 3A-3B).

Efficacy of doxorubicin and Akt inhibition in
doxorubicin-naive MB231 and MCF7 xenografts
in vivo

The efficacy of sham treatment, A-443654 or
doxorubicin, alone or in combination, was assessed in
NOD/SCID mice implanted orthotopically with
doxorubicin-naive MB231 or MCF7 human breast cancer
(n=5-6 mice/group).

The Akt inhibitor A-443654 was ineffective as
monotherapy in MB231 tumors in mice, but inhibited
tumor growth significantly in MCF7 tumors (Figure
4A-4B). Doxorubicin treatment yielded significant
tumor inhibition in both cancer subtypes. In MB231,
the combination of doxorubicin and A-443654 inhibited
tumor growth significantly compared to A-443654 or sham
treatment, but only if A-443654 was postponed for a week
after commencing doxorubicin administration (treatment
group B). In contrast, co-administration of A-443654
and chemotherapy (treatment group A) diminished the
tumor growth inhibition induced by doxorubicin alone.
In MCF7, the combination of doxorubicin and A-443654
yielded significant tumor growth inhibition as compared to
A-443654 or sham treatment, but only if the Akt inhibitor
and doxorubicin were administered concomitantly
(treatment group A). In both breast cancer models there
was no significant difference in tumor response between
doxorubicin alone and doxorubicin combined with
A-443654.

Subcutaneous Akt inhibitor injections caused a
7% weight loss after 14 days of treatment, which was
comparable to combined treatment with doxorubicin and
A-443654. However, the observed weight loss precluded
further extension of the A-443654 treatment period, to
assess whether long-term Akt inhibition could augment
the efficacy of doxorubicin. Unfortunately, two mice in
the doxorubicin and one mouse in the doxorubicin and
A-443654 group (A) had to be euthanized and taken out of
the MCF7 trial due to accidental injection of doxorubicin
into the gut wall and subsequent gut necrosis.

In a separate experiment, mice exposed to the
same treatment regimens as above were euthanized after
14 days and tumor tissue extracted for molecular
analysis (doxorubicin-naive MB231; n=3 mice/group
and MCF7; n=2 mice/group). As monotherapy,
A-443654 or doxorubicin yielded a heterogenous
increase in Akt phosphorylation in MCF7 and to
a lesser extent in MB231 xenografts, although not
significant by densitometry (Figure 4C-4D). Combined
treatment with A-443654 and doxorubicin increased
Akt phosphorylation in MCF7 xenografts significantly,
whereas the phosphorylation level of Akt in MB231
was unaffected by the combination regimen (Figure 4C-
4D). While Akt phosphorylation increased substantially
subsequent to 24 hours of A-443654 treatment in vivo
(Figure 2A-2D), this increase was less pronounced in
MB231 and MCF7 xenografts after two weeks of
A-443654 treatment (Figure 4C-4D).

Potential effects of Akt inhibition was further
monitored by analyzing downstream target effects (S6K
phosphorylation status). In doxorubicin-naive MB231
tumors, protein analysis demonstrated significantly reduced
S6K phosphorylation after treatment with doxorubicin alone
or combined with A-443654 (Figure 4C). In doxorubicin-
naive MCF7 tumors, A-443654 or doxorubicin, either
alone or in combination, reduced mTOR phosphorylation
(Figure 4D). Gene expression analysis of PTEN, AKT1
and S6K in tumors extracted 14 days after commencing
therapy (Supplementary Figure 3) demonstrated a
significant decrease in AKT1 in MCF7 tumors subsequent
to doxorubicin exposure, but apart from this no definite
differences between the treatment groups were observed in neither MCF7 nor MB231.

Gene expression changes induced by anthracyclines in human breast cancers

Next, to compare with the preclinical results, we examined how anthracyclines affected acute and chronic tumor gene expression by analyzing breast cancer samples obtained before and 24 hours after the first epirubicin (60 mg/m² i.v.) course, or before and after 16 weeks of weekly doxorubicin (14 mg/m² i.v.). All 24 tumors collected in the dose dense epirubicin trial (ClinicalTrials.gov NCT00496795) expressed PTEN, AKT1 and S6K, before and/or after treatment (Supplementary Figure 4). Among the patients treated with epirubicin, AKT1 gene expression increased significantly (p=0.016) in tumors that subsequently regressed on treatment (PR; n=9), whereas no change was observed in tumors that did not respond (SD, PD; n=15, Figure 5A). The mRNA levels of PTEN and S6K did not change significantly, neither among responders nor non-responders (Figure 5A). Stratifying patients according to ER status, neither AKT1, PTEN nor S6K mRNA levels were influenced by epirubicin exposure among ER negative tumors (n=11), independent of clinical response to therapy (Figure 5B). Interestingly, among the ER positive tumors (n=13), AKT1 (p=0.040) as well as PTEN levels (p=0.039) increased significantly in patients who responded to therapy (n=6); whereas no change in neither AKT1 nor PTEN levels was observed among the non-responders (n=7, Figure 5B). Furthermore, S6K decreased significantly (p=0.027) in ER positive tumors that did not respond to therapy (n=7, Figure 5B).

After a median follow-up of 69 months, six out of 24 patients from the dose dense trial had developed breast cancer recurrence; no difference in gene expression changes between patients relapsing and those not relapsing was observed (Supplementary Figure 4).

To assess potential long-term effects of anthracycline treatment, tumor samples collected from 30 patients with locally advanced breast cancers, before and after 16 weeks of doxorubicin [30, 31], were examined for long-term gene expression changes of PTEN and AKT1 (Supplementary Figure 5). Analysing all patients together, no change in neither AKT1 nor PTEN expression was observed. However, stratifying patients based on response to therapy, PTEN expression increased significantly (p=0.033) among non-responders (patients having a PD or SD on therapy; n=17), in particular among ER negative non-responders (n=4; p=0.026; Figure 6A-6B). In contrast,

Figure 3: Cytotoxicity of A-443654 and doxorubicin in doxorubicin-naïve and doxorubicin-resistant human breast cancer cell lines. In vitro cytotoxicity of doxorubicin (1 μM), Akt inhibitor A-443654 at IC30 concentration, or the combination, in doxorubicin-naïve or resistant MB231 (A) and MCF7 (B) cells, after 24 hrs drug exposure. WST-1 cell proliferation assay, absorbance read at optical density (OD) 450 nm, normalized to readings in control wells exposed to equivalent volumes of DMSO (doxorubicin stock solvent) and HPMC (dissolvent for A-443654). (C-D) Western blots for PTEN and Akt-mTOR-S6K signaling in MB231 (C) and MCF7 (D) tumors, harvested the last day of A-443654 treatment. Whole cell lysate, 30 μg protein loaded per lane. The sample order on the blot pictures has been rearranged to enhance readability. Densitometries for western blot (C-D) depict the relative protein expression, normalized to actin. Phosphorylated Akt (p-Akt) and mTOR (p-mTOR) were normalized to actin and thereafter to total Akt and mTOR, respectively. Bars represent the mean protein expression for experiments performed in duplicate (D) or triplicate (C) ± SEM. *p<0.05
while 22 out of 30 patients had relapsed during a median follow-up of 235 months, gene expression changes did not correlate to long-term outcome (Supplementary Figure 5).

The mutation status of PIK3CA and TP53 was assessed in all the above tumor samples (Supplementary Figure 4 and Supplementary Figure 5). The low number of tumors harboring PIK3CA mutations precluded any correlation analysis between PIK3CA mutation status and the gene expression changes observed. Among tumors assessed before and 24 hours after the initial epirubicin course, no difference in PTEN or AKT1 gene expression was observed regardless of response to

Figure 5: AKT1, PTEN and S6K gene expression in human breast cancers before and 24 hrs after epirubicin exposure. (A) Box plots of gene expression of PTEN, AKT1 and S6K normalized to RPLP2 in human breast cancer samples, before and 24 hrs after the first epirubicin dose, from patients in the dose dense trial. chemotherapy, if subdivided into TP53 wt (n=16) and TP53 mutated tumors (n=8). Upregulated AKT1 24 hrs after the first epirubicin exposure was observed in six out of 13 ER positive breast cancers which subsequently regressed on this treatment (Figure 5); and four out of these six tumors where AKT1 increased harbored wt TP53 status (Supplementary Figure 4).

In tumors examined before and after 16 wks of doxorubicin, if split by TP53 mutation status (TP53 wt; n=15, TP53 mutated; n=15), PTEN increased significantly after treatment (p=0.02) in tumors harboring TP53 mutations that did not respond to doxorubicin treatment (n=8), whereas no change was observed among responders (n=7) or among TP53 wt tumors (data not shown). Also, there was no significant change in AKT1, among responders or non-responders to doxorubicin, if the subgroups were split by TP53 mutation status.

DISCUSSION

Patients with ER positive as well as ER negative breast cancer obtain improved survival from adjuvant polychemotherapy [17], but the benefit of chemotherapy is less in typical luminal A tumors with strong ER expression compared to other subtypes [18]. The mutational landscape of breast cancer subtypes differ substantially, with a high prevalence of activating PIK3CA mutations in ER positive, luminal or HER2-enriched tumors, whereas inactivating TP53 mutations are commonly observed in ER negative subtypes [4]. Moreover, while activating AKT1 mutations are rare in human breast cancers, they occur more frequently among luminal or HER2-enriched (2-4%) than basal-like tumors (0%) [4], suggesting a selection pressure towards increased Akt signaling in these neoplasms. Accordingly, the PI3K-Akt-mTOR pathway has been targeted therapeutically to counteract acquired resistance to endocrine therapy and combined trastuzumab-chemotherapy in clinical trials [1, 3, 5, 19]. However, the importance of PI3K-Akt-mTOR signaling to chemoresistance has not been fully elucidated.

Here, we systematically explored alterations in this pathway in response to anthracycline and/or Akt inhibition in ER positive and negative breast cancer cell lines and their concomitant xenografts and to anthracycline treatment in human breast cancers.

We established that the Akt inhibitor A-443654 reduces cell proliferation both in the ER positive MCF7 and the ER negative MB231 cell line in vitro. However, Akt inhibition yielded tumor regression in MCF7 and not MB231 in vivo, and doxorubicin significantly augmented this tumor response only in MCF7 xenografts. Of notice, A-443654 caused significant weight loss which was intolerable beyond 14 days, and we therefore could not explore its full potential alone or combined with anthracyclines. Toxicity was a similar problem in the first clinical trials testing Akt inhibitors, although next generation compounds seem better tolerated [20] and should be tested in long-term combination schedules with anthracyclines. Importantly, the combined efficacy of A-443654 and doxorubicin was dependent on timing, where concomitant administration of the Akt inhibitor and chemotherapy was required for optimal tumor regression in MCF7 xenografts. In contrast, co-administration of A-443654 with doxorubicin reduced the efficacy of doxorubicin in MB231 xenografts. Doxorubicin yielded rapid upregulation of phosphorylated Akt in MCF7 cells in vitro, whereas long-term exposure and induction of doxorubicin resistance was required to upregulate phosphorylated Akt in MB231. This may explain the different efficacy with respect to timing between doxorubicin and the Akt inhibitor in the two cell lines.

Previous studies have revealed A-443654 to act as an ATP competitive inhibitor of Akt; as such, it increases Akt phosphorylation while at the same time inhibiting Akt downstream signaling [15, 16]. Accordingly, A-443654 rapidly increased Akt phosphorylation, which was more pronounced in the MCF7 as compared to the MB231 cell line, and suggesting a particular responsiveness of the PI3K-Akt-mTOR pathway in ER positive breast cancer cells. However, the cytotoxicity of A-443654 was comparable between MCF7 and MB231, and similar inhibition of Akt downstream signaling was observed in the ER positive and ER negative cell lines. In contrast, the activity of A-443654 was profoundly reduced in doxorubicin-resistant MB231 cells, where the inhibition of Akt signaling by A-443654 was abrogated. Interestingly, doxorubicin resistance enhanced the cytotoxicity of A-443654 significantly in MCF7, with maintained inhibition of Akt downstream signaling. The mechanisms behind the enhanced activity of A-443654 in doxorubicin-resistant MCF7 cells remain to be established. However, the baseline Akt phosphorylation level is higher in the doxorubicin-resistant MCF7 cell line, as compared to doxorubicin-naïve MCF7 cells, potentially explaining the increased cytotoxicity towards A-443654.

In line with previous observations [10, 21], we established that doxorubicin exposure increases Akt phosphorylation in the ER positive MCF7 and T47D human breast cancer cell lines, but not the ER negative MB231 cell line. Herein we expand upon these data to show that MCF7 cells made resistant to doxorubicin exhibit a higher constitutive Akt phosphorylation levels which is not affected by further doxorubicin exposure. The increased cytotoxicity of Akt inhibition in doxorubicin-resistant MCF7 breast cancer cells points to a potential use of such a drug class in ER positive breast cancer, in particular if resistance to anthracycline has developed and Akt phosphorylation levels are elevated. Importantly, while the Akt inhibitor exhibited increased cytotoxicity in doxorubicin-resistant compared to doxorubicin-naïve MCF7 breast cancer, we did not examine whether Akt inhibitors can be used to reverse doxorubicin resistance, but this issue should be addressed in future trials. However, upregulated PI3K-Akt-mTOR signaling is...
clearly associated with chemoresistance, which has been shown in various preclinical cancer models, and chemotherapy response can be augmented in this setting by simultaneous PI3K or Akt inhibition [10, 11, 22–24], in particular in ER positive breast cancer [10, 22].

Finally, we provide clinical data demonstrating that increased AKTI1 gene expression 24 hours after epirubicin exposure characterizes ER positive, but not ER negative, primary breast cancers that subsequently regress on anthracycline treatment. Interestingly, no change in tumor AKTI1 expression was observed in patients after 16 weeks of doxorubicin, suggesting an intermittent Akt response where the efficacy of Akt inhibitors could depend on timing. Furthermore, an increased AKTI1 mRNA level 24 hrs after the first chemotherapy course could potentially be used as a biomarker identifying ER positive tumors likely to respond to chemotherapy. The reason why elevated AKTI1 mRNA is associated with good response remains to be elucidated. However, if high AKTI1 translates into increased Akt activation throughout the duration of chemotherapy, chronic Akt activation may promote senescence and apoptosis by downregulating MDM2 and increasing p53 in breast cancers with preserved p53 function [25, 26]. Of notice, among the ER positive breast cancers which responded to epirubicin, four out of six tumors with upregulated AKTI1 after chemotherapy harbored wt TP53 status.

In contrast to the patient data, AKTI1 mRNA levels were not affected in the MB231 and MCF7 human breast cancer cell lines after 24 hrs chemotherapy exposure. The reason for this discrepancy remains to be elucidated, but could be due to the admixture of tumor cells and stroma in patient tumor samples in contrast to the pure tumor cell content in the in vitro cultures. Unfortunately, we did not have patient samples available for protein analysis of Akt and Akt signaling to compare with the gene expression data. Furthermore, the induction of Akt phosphorylation by A-443654 which was observed in MB231 and MCF7 in vitro, was not detected in the corresponding xenografts. Again, the admixture of tumor cells and stroma cells in vivo, as well as the heterogeneity between the xenografts may explain the lack of correlation between the in vivo and in vitro findings. Moreover, the xenografts used for the protein analysis were extracted after 14 days of treatment compared to the 2 hrs and 24 hrs of treatment in the in vitro experiments. The reason why decreased PTEN mRNA levels did not decrease PTEN protein levels in MB231 cells after 24 hrs exposure to doxorubicin also remains to be established. Whereas rapid changes in gene expression are induced by the chemotherapy, protein changes may take longer to develop due to the relatively long half-life of PTEN (>8 hrs) [13]. Furthermore, there is no strong correlation between PTEN mRNA and PTEN protein levels in human breast cancer [14], which could be explained by post-transcriptional and post-translational mechanisms modifying protein expression and stability.

In conclusion, our data point to upregulated Akt expression as a recurrent initial response to anthracyclines in ER positive human breast cancers, and in particular, among patients who respond to chemotherapy. Furthermore, we observed increased sensitivity to Akt inhibition in doxorubicin-resistant, compared to doxorubicin-naïve, ER positive MCF7 breast cancer cells. Accordingly, the benefit of Akt inhibition is clearly context-dependent, with respect to ER status and previous anthracycline exposure. Thus far, the role of Akt inhibitors to augment the efficacy of chemotherapy in solid tumors has not been dealt with to a large extent, despite promising preclinical and clinical data [23, 24, 27–29] and should be explored further, in particular in ER positive breast cancers.

MATERIALS AND METHODS

Ethical declaration

The authors declare that the experiments within this paper comply with the ethical standards and current laws in Norway.

Cell lines

The ER positive MCF7 and T47D and the ER negative MDA-MB-231 (MB231) human breast cancer cell lines were used for all the preclinical experiments. For cell growth conditions and cell line identity, see Supplementary methods. Doxorubicin (Adriamycin, Pfizer) was diluted to 2 mg/ml in DMSO 99% for cell culture experiments, stored as frozen aliquots (-20°C), and prepared fresh by dilution in complete cell culture medium for each experiment to preserve drug stability. Control cells were always incubated with an equivalent volume of DMSO 99% as cells exposed to medium containing doxorubicin. A-443654 (AbbVie) was dissolved in 0.2% hydroxypropyl methylcellulose (HPMC, Sigma) prior use. For comparison, control cells were given an equivalent volume of HPMC as those cells exposed to A-443654.

Generation of doxorubicin-resistant cell lines

Doxorubicin-naïve MB231 and MCF7 cells were grown in gradually increasing doxorubicin concentrations over several months. When the cells were subconfluent they were exposed to growth medium containing twice the previous concentration of doxorubicin, and this was repeated until a dose was reached, where the cells would not expand any further. At this point, the cells had acquired resistance to doxorubicin 1.5 µM (MB231 dox-res) and doxorubicin 0.65 µM (MCF7 dox-res), each by exposure for 48 hrs. The cells were maintained in doxorubicin-free medium, but exposed to doxorubicin at their resistance

www.impactjournals.com/oncotarget
dose every two weeks to maintain resistance. Control cells were propagated in medium with an equivalent volume of DMSO. To determine the acute response to doxorubicin in doxorubicin-resistant cells, the cells were seeded at 3x10^5 in 6-well dishes (Nunc) and incubated for 24 hrs until 70% confluence. The medium was then replaced by medium containing either doxorubicin or DMSO, and cells were incubated for another 24 hrs before the cells was harvested and RNA and protein isolated.

**In vitro activity and cytotoxicity of A-443654 and doxorubicin**

Subconfluent MB231 and MCF7 cells (in T25 flasks), either doxorubicin-naïve or doxorubicin-resistant, were exposed to increasing concentrations of Akt inhibitor A-443654 or HPMC (control) to assess the influence on Akt phosphorylation, and protein was harvested after 2 hrs. To evaluate the influence of the Akt inhibitor on Akt phosphorylation and downstream signaling after 24 hrs, cells were exposed to A-443654 at the IC30 (1 μM MB231, 0.5 μM MCF7), before harvesting protein.

To assess the influence of doxorubicin +/- Akt inhibitor A-443654 on cell viability, 5000 MB231, 1500 MCF7 or 20000 T47D cells were seeded per well in 96-well plates (Falcon), and allowed to attach over night in complete medium. Thereafter the drug(s) was added, before culturing the cells for another 24 hours. Cell proliferation after drug exposure was assessed by the WST-1 assay (Roche), as described in the manufacturer’s manual.

**Gene expression analysis and western blots**

Therapy-induced changes in gene and protein expression were assessed using qPCR and western blot analyses. Detailed methods, primers and antibodies are described in Supplementary methods.

**In vivo cytotoxicity of A-443654 and doxorubicin**

NOD/SCID mice were bred and mouse crossings performed inhouse at the Animal Facility, University of Bergen. Adult mice of fertile age were anesthetized with isoflurane (Baxter) before 1x10^6 MCF7 or MB231 cells were injected orthotopically in the fourth left inguinal mammary gland. The tumors were measured every 3-4 days using Vernier calipers, and tumor volumes were calculated using the formula a*b/2, where a and b are the shorter and longer diameter of the tumors respectively. Treatment commenced when the tumors had reached 4-6 mm in diameter, and the animals were stratified into groups according to tumor size. The mice were euthanized if signs of serious distress occurred or when the first tumor in any treatment group had a tumor diameter exceeding 17 mm.

The maximum tolerable dose (MTD) of doxorubicin, given weekly for two following weeks, with or without the Akt inhibitor A-443654 was initially assessed in non-tumor bearing NOD/SCID mice before commencing the therapy trial in xenograft-implanted mice. Doxorubicin was dissolved in 0.9% NaCl (Baxter) and injected i.p. once weekly for two consecutive weeks to establish an MTD of 1.25 mg/kg qW. A-443654 was dissolved in HPMC and administered subcutaneously at 3.75 mg/kg BID for 14 consecutive days, based on dosage reported elsewhere [16]. In the combination treatment groups, administration of A-443654 commenced either upfront (A), 24 hours after the first doxorubicin injection (to treat primary resistance due to high Akt signaling), or started as a delayed regimen (B) at the same time as the second doxorubicin injection (to counteract doxorubicin-induced acquired resistance due to upregulated Akt signaling). Control mice were given 0.2% HPMC s.c. and 0.9% NaCl i.p.

In a separate experiment, three MB231 mice and two MCF7 mice per group were sacrificed at the end of 14 days of treatment (as given in the treatment trial above) for protein analysis. All animals were euthanized by cervical dislocation two hours after the last injection of A-443654 or sham treatment, and tissue samples from the tumor as well as all organs snap-frozen on liquid N2 and stored at -80°C.

The animal experiments were performed with the approval of and in accordance with guidelines by the Norwegian State Commission for Laboratory Animals.

**Patient breast cancer samples**

The short-term effect of anthracyclines on PTEN, AKT1 and S6K gene expression was assessed in a selected cohort of 14 ER positive and 11 ER negative breast cancers biopsied before and 24 hrs after receiving their first course of epirubicin as part of the “dose dense trial” (ClinicalTrials.gov NCT00496795) wherein treatment-naïve patients with locally advanced breast cancer were given doxorubicin neoadjuvant epirubicin 60 mg/m² q2w (four courses) followed by docetaxel 100 mg/m² q2w (four courses). The presence of pre-treatment PIK3CA and TP53 mutations in all tumor samples were examined as described in Supplementary methods. One ER positive tumor pair was excluded due to poor RNA quality, leaving 24 tumor pairs for analysis.

Furthermore, to analyze for long-term effects of anthracyclines on PTEN and AKT1 mRNA levels, gene expression was assessed in paired tumor samples from 30 patients with treatment-naïve locally advanced breast cancer in the “doxorubicin trial”, biopsied before and after 16 wks of neoadjuvant doxorubicin 14 mg/m² qW treatment [30, 31]. Briefly, tumor pairs for mRNA analysis were available from 24 patients with ER positive and six patients with ER negative locally advanced breast cancer.
The dose dense and doxorubicin clinical trials were approved by the Regional Ethical Committee of the Western health region in Norway (reference numbers: 192/91-69.91 and 079.06). All patients gave their informed consent before inclusion. Accordingly, all procedures performed in these clinical trials were in accordance with the national ethical standards and with the 1964 Helsinki declaration and its later amendments.

Statistics

SPSS 22/PASW 17.0 and Graph Pad Prism v6 software packages were used for statistical analyses. Correlation analysis between \( \text{AKT1} \) and \( \text{PTEN} \) or \( \text{S6K} \) mRNA expression levels was performed using Spearman’s rho. Comparison of gene or protein expression levels was performed using the Student’s \( t \)-test for paired samples or two independent samples, as appropriate. All \( p \)-values reported are two-tailed, and \( p<0.05 \) was considered statistically significant.

Availability of data and materials

All raw data generated from the experiments presented are available from the corresponding author upon request. The data subset used for mutational calling of \( \text{TP53} \) and \( \text{PIK3CA} \) in the “dose dense trial” was extracted from whole exome sequencing data, and the DNA sequences are available from the corresponding author upon request.

Authors’ contributions

HPE and PEL designed the studies. SY, HPE, SK and PEL wrote the manuscript. SY, EA and HPE performed and supervised the laboratory experiments, the preclinical studies, and analyzed the results. SK helped with experimental design and analyzed the mutational data extracted from the whole exome sequencing dataset. PEL was principal investigator for the clinical trials. IRS, HPE and PEL conducted the clinical trials, performed response evaluations and collected follow-up data. SY and HPE performed statistical calculations. All authors have read and approved the final version of the manuscript.

ACKNOWLEDGMENTS

We gratefully acknowledge the contribution made by the patients included in the dose dense and doxorubicin trials. Furthermore, the trials could not have been conducted without the skillful expertise of colleagues in the Departments of Oncology, Radiology and Surgery at Haukeland University Hospital, and the technical assistance from E.N. de Faveri and D. Ekse.

CONFLICTS OF INTEREST

The authors declare they have no conflicts of interest.

FUNDING

The current work was supported by generous donations by Trond Mohn to the Mohn Cancer Research laboratory, and grants from Bergen Medical Research Foundation, Helse Vest and the Norwegian Cancer Society. A-443654 was kindly provided by AbbVie.
