Abstract

Plants present a delimited reservoir of biologically active compounds. Many plants synthesize several compounds of secondary metabolism, such as alkaloids, terpenoids, phenolics, steroids, etc. Such compounds are generally thought to be involved in plant–insect interactions. Phytoecdysteroids are a class of chemicals that plants synthesize; these compounds are analogues of molting hormones produced by insects. In this work, the effect of the 20-hydroxyecdysone, which is a molecule that belongs to the family of phytoecdysteroids, was tested on an insect pest, *Tribolium castaneum* (Herbst). Firstly, the effect of this molecule on post-embryonic development parameters was tested after ingestion at 300, 600, 900, and 1,200 ppm. Secondly, the effect of the 20-hydroxyecdysone was also tested on the biological parameters (proteins, alpha-amylase, detoxification enzymes). The results of the post-embryonic parameters test showed an important induction of larval mortality and a significant reduction of pupation and adult emergence rates. On the other hand, the test on the biological parameters showed that the 20-hydroxyecdysone caused a significant decrease in the levels of soluble proteins in treated larvae. In addition, the alpha-amylase activity was significantly inhibited by the ingestion of the phytoecdysteroid. And there was also a disruption of detoxification enzymes. The whole of the disturbances recorded in this work prove that phytoecdysteroids are thought to have potential value on *T. castaneum* control.

Key words: insect pest, phytoecdysteroid, toxicity, biochemical parameter

Plants are continually exposed to damage caused by many agents including insects, (Talbot 2005). The life of those pests is ensured by the presence of green plants, which are considered as an important source of nutrition for heterotrophic living beings. Therefore, a better understanding of the plant–insect interaction is really necessary (Schoonhoven et al. 2005). Statistics show that the tithe of annually produced plant biomass is consumed by insects, which makes insects a huge threat to agricultural productivity (Stamp 1996, Coupe and Cahill 2003). Following the damage produced by these insect pests, plants induce resistance in response to these phytophagous (Stamp 1996, Dicke and Loon 2000). In fact, plant resistance can be induced by the biosynthesis of groups of secondary metabolites such as phenolics, terpenes, alkaloids, and steroids (Fraenkel 1959).

Phytoecdysteroids are natural steroids synthesized by plants. They have a similar chemical structure to ecdysteroids, which are molting hormones produced by insects. Phytoecdysteroids were found to have defensive potential against pests’s attacks (Dinan 2001, Schmelz et al. 2002). Blackford and Dinan (1997) studied the effect of ingested phytoecdysteroids against *Cynthia cardui* (Linnaeus, 1758) (Lepidoptera: Nymphalidae) larvae, and they found that phytoecdysteroids prolonged the larval and pupal periods, induced mortality, and provoked a disruption of the adult emergence. Tanaka et al. (1994) reported that phytoecdysteroids disrupted the physiological parameters of *Bombyx mori* (Linnaeus, 1758) (Lepidoptera: Bombycidae). However, certain species remain unsuscetible to the exogenous application of phytoecdysteroids; it is the case of *Heliothis virescens* (Fabricius, 1777) (Lepidoptera: Noctuidae) (Kubo et al. 1987) and *Ostrinia nubilalis* (Hübner, 1796) (Lepidoptera: Pyralidae) (Gelman et al. 1991).

Diverse researchers have showed that sterols affect negatively the biochemical and physiological parameters of herbivorous insects. However, the losses of stored grains caused by insect infestation is a serious problem. Therefore, testing the effect of phytoecdysteroids on insect pests of stored products should be focused on by more studies.
Chaitanya et al. (2011) reported that the ingested phytoecdysteroids disrupt the physiological parameters of Corcyra cephalonica (Stainton, 1866) (Lepidoptera: Pyralidae). Rharabe et al. (2009) showed that phytoecdysteroids provoke a disruption in the post-embryonic parameters of Plodia interpunctella (Hübner, 1813) (Lepidoptera: Pyralidae).

Among insect pests, Tribolium castaneum (Herbst) (Coleoptera: Tenebrionidae) is the major pest that causes quantitative and qualitative damage to post harvested products (Burkholder and Faustini 1991). In this study, the effect of 20-hydroxyecdysone, a molecule belonging to the family of phytoecdysteroids, was tested on the development, and alpha-amylase and detoxification enzyme activities of the stored products' insect pest, T. castaneum. We chose 20-hydroxyecdysone in preference to any other molecule for this study because it is the most common and the main phytoecdysteroid contained in plants and also the major biologically active ecdysoider of insects (Dinan 2001).

Materials and Methods

Insect Rearing

Tribolium castaneum was raised in the laboratory under standard conditions of temperature of 26 ± 2°C, relative humidity of 75 ± 5% and subjected to a diet consisting of wheat flour with yeast in a proportion of 5%. Five larval instars were displayed by T. castaneum under these conditions. Larvae of the fourth stage are left to fast for 20 h before submitting them to experimentation in order to induce them to take food.

Post-Embryonic Development

20-Hydroxyecdysone (95% of purity) was dissolved in 5% methanol in distilled water. The phytoecdysteroid tested was mixed with wheat flour at concentration of 300, 600, 900, and 1,200 ppm. For control lot, methanol alone in distilled water was added to diet. The solvent was evaporated from the diet at 37°C in an oven for 48 h. Petri dishes were prepared in which starved larvae were put (with no food) to ensure that the effect was due to 20-hydroxyecdysone ingestion and not to a deterrence effect. Mortality, pupation, and adult emergence rate were observed every 2 d over 26 d. Mortality was identified by brown coloration with no noticeable movements. Note that insects of T. castaneum were maintained under standard conditions throughout the monitoring period. Ten larvae were added to each petri dish for all the experiments and five replicates (five petri dishes) were performed for treated, starved, and control larvae.

Biochemical Parameters

The biochemical study of some parameters such as the rate of proteins, and alpha-amylase and detoxification enzyme activities was established in relation to the toxic effects resulting from the ingestion of the 20-hydroxyecdysone.

Ten replicates were performed for treated, starved, and control larvae. For the biochemical parameters, larvae were treated for 7 d before starting the analysis.

Soluble Protein Rate

For protein measurements, three larvae were homogenized in 1 ml of Tris-HCl buffer (50 mM, pH 7) and soluble protein content was determined according to the method of Bradford 1976).

Alpha-Amylase Activity

Measurement of alpha-amylase activity was performed according to (Valencia et al. 2000) with minor amendments. Three larvae were homogenized in acetate buffer (50 mM) with NaCl (10 M) and CaCl$_2$ (20 M) at pH 5. Three larvae were incubated at 37°C for 15 min. Then, the iodine reagent was added, and the mixture centrifuged at 4,000 x g for 10 min. The alpha-amylose activity was expressed by the quantity of starch consumed per unit of time by larvae (the absorbance was read at 580 nm).

Detoxification Enzymes

Esterase activity was determined using 1-NA (1-naphthyl acetate). Three larvae were added to mixture (pH 6.5) and incubated 1 h at 30°C. The absorbance was read at 600 nm. Specific activity was calculated by using a standard curve of 1-naphthol according to (Gomori 1953).

Glutathione S-transferase (GST) activity was measured using 1 mM CDNB (1-chloro-2,4-dinitrobenzene), 5 mM reduced glutathione, and 0.1 M Tris buffer, pH 7. The increment in absorbance at 340 nm was recorded during 5 min at 30°C to determine the nanomoles of substrate conjugated per minute per milligram of protein, using a molar extinction coefficient of 9.6 mM/cm (Habig et al. 1974).

P450 monooxygenases activity was measured according to Masters et al. (1965). Mixture of NADPH generating system at pH 7 and cytochrome c solution was incubated 1 h at 30°C. The reaction was stopped by methanol, then centrifuged at 12,000 rpm for 5 min. The absorbance was read at 550 nm to determine the nanomoles of cytochrome c reduced per minute per milligram of protein, using a molar extinction coefficient of 27.6 mM/cm.

Statistical Analysis

The results obtained were analyzed by the analysis of variance (ANOVA) using Statistica (1997) software to determine the statistical significance in the effect of 20-hydroxyecdysone on biological and physiological parameters of T. castaneum. Honest Significant Difference (HSD) testing was carried out using the Tukey test with untreated group as the control. A significant level of 0.05 was used for all statistical tests.

Results

Effects of 20-Hydroxyecdysone on Development Parameters

Ingestion of 20-hydroxyecdysone by the larvae of T. castaneum induced mortality from the 4th day of treatment for the highest dose (1,200 ppm) and increased to achieve its highest rate by the 14th day (Fig. 1). The percentage of inhibition compared to the control was (42%). For the other doses, mortality began from the sixth day and achieved its maximum either by the day 10 (for 300 ppm) or 12 (for 600 ppm and 900 ppm), whereas the mortality of starved larvae reached it maximum by day 14. It is noted that control larvae did not show mortality throughout the monitoring period. Statistical analysis showed that larval mortality effect was very highly significant for all treatment and for starved larvae as compared to the control (F = 51.2–90.1, df = 5–18; P < 0.001).

Results of pupation for control, treated, and starved larvae are grouped together in Fig. 2. Pupation began on the sixth day in control larvae and then increased rapidly throughout the monitoring period to reach its maximum value on day 14. In larvae treated with 20-hydroxyecdysone, precocious pupation appears 4 d earlier at 1,200 ppm and 900 ppm and 2 d earlier at 600 and 300 ppm as compared to control larvae. For starved larvae, we did not record any pupation throughout the monitoring period. Statistical analysis show that the treatment as well as starvation had a very highly significant effect on pupation (F = 8.9–25.6; df = 5–18; P < 0.001).
The emergence rate of adults is calculated from the number of pupae formed. Our results showed that this percentage was significantly affected by the presence of the 20-hydroxyecdysone in larval diet (Fig. 3). The adult emergence started from the 16th day for the control larvae and reached its highest rate on day 26. Similarly, for treated larvae with doses of 300, 600, and 900 ppm, it started on day 16 as well. However, for larvae treated with the dose of 1,200 ppm, the adult emergence began 2 d earlier. It is noted that the adult emergence rate increased throughout the monitoring period in larvae treated with all doses. Statistical analysis showed that larval mortality effect was very highly significant for all treatment and for starved larvae as compared with control \( (F = 19.8–77.4; \text{df} = 5–18; P < 0.001) \).

**Effects of 20-Hydroxyecdysone on Soluble Protein Rate**

Protein content in control larvae decreases very significantly \( (P < 0.001) \) for starved and all treated larvae in a dose-dependent manner (Table 1). Protein content in starved larvae of *T. castaneum* is also significantly reduced \( (P < 0.001) \).

**Effects of 20-Hydroxyecdysone on Alpha-Amylase Activity**

The results of the assay for alpha-amylase activity in control larvae, larvae treated with different doses of 20-hydroxyecdysone, and starved larvae are shown in (Table 1). The amount of starch consumed in the larvae treated with 20-hydroxyecdysone decreased, as the dose of the treatment increased, in a very high significant way \( (P < 0.001) \).

**Effects of 20-Hydroxyecdysone on Detoxification Enzymes**

The results of 20-hydroxyecdysone effect on detoxification enzymes of *T. castaneum* are regrouped in (Table 2). In treated larvae, esterase activity using 1-Na as substrate increased at low concentration (300 ppm) but decreased when using higher concentration (1,200 ppm) of 20-hydroxyecdysone.

GST using CDNB as substrate increased in treated larvae in a dose-dependent manner. Statistical analysis shows that 20-hydroxyecdysone had a very highly significant effect \( (P < 0.001) \) on GST activity for all doses.
Fig. 3. Effect of 20-hydroxyecdysone on adult emergence of Tribolium castaneum. Each point represents the mean ± SE of five replicates. Means in the same column followed by different letters indicate that the difference between controls and treated or starved larvae is statistically significant as determined by the Tukey’s HSD test. Between the letters ‘a’ and ‘b’, the effect is significant (P < 0.05). Between the letters ‘a–c’, the effect is very significant (P < 0.01). Between the letters ‘a–d’, the effect is very highly significant (P < 0.001).

Table 1. Effect of 20-hydroxyecdysone on protein and alpha-amylase activity of Tribolium castaneum larvae after 7 d of treatment

| Treatment   | Protein (µg/larvae) | α-Amylase (µg of starch consumed/larva) |
|-------------|---------------------|---------------------------------------|
| Control     | 233.15 ± 24a        | 174.63 ± 1.7a                         |
| 300 ppm     | 151.32 ± 15b        | 161.25 ± 2.06b                        |
| 600 ppm     | 149.13 ± 5b         | 150.53 ± 2.5b                         |
| 900 ppm     | 110.07 ± 20c        | 145.15 ± 2.2c                         |
| 1,200 ppm   | 95.7 ± 16c          | 134.95 ± 1.9c                         |
| Starved     | 48.34 ± 7.7d        | 132.38 ± 2.6c                         |

Means in the same column followed by different letters indicate that the difference between controls and treated or starved larvae is statistically significant as determined by the Tukey’s HSD test. Between the letters ‘a’ and ‘b’, the effect is significant (P < 0.05). Between the letters ‘a–c’, the effect is very significant (P < 0.01). Between the letters ‘a–d’, the effect is very highly significant (P < 0.001).

P450 monoxygenases activity increased only at 300 ppm; this activity was inhibited significantly when larvae of T. castaneum were exposed to 1,200 ppm of 20-hydroxyecdysone. Starved larvae showed also a significant inhibition of this activity.

Discussion

In this study, it was found that the 20-hydroxyecdysone possesses larvicidal activity against T. castaneum. Obtained results demonstrated that when the phytoecdysteroid is added to the food of larvae, it causes negative effects that occur through significant larval mortality, and through inhibition of development. Similar effects were observed after edcsyne analogs had been ingested in Tribolium confusum (du Val, 1861) (Coleoptera: Tenebrionidae) larvae diet, they inhibited growth and development of this insect pest (Robbins et al. 1970). A developmental anomalies during metamorphosis were also shown after certain phytoecdysteroids had been incorporated into an artificial diet of larvae of the leek-moth Acrolepiopsis assectella (Zeller, 1839) (Lepidoptera: Hyponomeutidae) (Arnault and Sláma 1986). Rharrabe et al. (2010) found that ingested phytoecdysteroids increased mortality and provoked a disruption of development in P. interpunctella (Hübner) as well.

The obtained results in this study revealed that the mortality increased significantly after ingestion of 20-hydroxyecdysone in a dose-dependent manner, and the larval mortality was registered due to toxic effect of this phytoecdysteroid. Precocious pupation and adult emergence were registered, with a reduction of their percentages compared to controls. Similar effects were observed when phytoecdysteroids ingested to the diet of Leptinotarsa decemlineata (Say, 1824) (Coleoptera: Chrysomelidae) larvae (Zolotar’ et al. 2001), P. interpunctella (Hübner) (Rharrabe et al. 2009). Macedo et al. (2011) reported that the incorporation of Tolisin from Talisia esculenta (A. St. Hil) Radlk (Sapindales: Sapindaceae) seeds into an artificial diet fed to Anticarsia gemmatalis (Hübner, 1818) (Lepidoptera: Noctuidae) affects larval growth, pupal weight, development and mortality, adult fertility, and longevity and produces malformations in pupae and adult insects. Boukouvala et al. (2016) demonstrated that the exposure to pyrrole derivatives causes insecticidal effect against T. confusum.
To fully clarify the effects of 20-hydroxyecdysone on *T. castaneum*, the results of ingested phytoecdysteroid on biochemical parameters were analyzed. These results revealed a significant drop in protein rate in larvae of *T. castaneum*. This drop could be due to a reduction of protein synthesis mainly in the fat body following the deterioration of the internal tissues of insects, or to a strong mobilization of proteins as a response to the nutritional stress caused by the exposure of the larvae to the phytoecdysteroid applied. Similar effects were observed after exposure of *P. interpunctella* larvae to 20-hydroxyecdysone, and it induces a decrease in protein content (Rharrahe et al. 2009). Such disruption was recorded in *B. mori* after ingesting phytoecdysteroids from *Radix adyranthes* (Blume) (Caryophyllales: Amaranthaceae) (Miao et al. 2004). Similar effects were also observed after the azadirachtin ingestion in *Schistocerca gregaria* (Forsskal, 1775) (Orthoptera: Acrididae) (Rao and Subrahmanyan 1986) and *P. interpunctella* (Rharrahe et al. 2008). Concerning digestive enzyme, the results clearly showed that the ingestion of 20-hydroxyecdysone causes an inhibition of alpha-amylase activity in a dose-dependent manner. This effect can be due to a direct inhibition of the activity of the enzymes themselves or indirectly to a perturbation of some neuromolecules (as Sulfakinin) that involved in alpha-amylase signaling of the enzymes themselves or indirectly to a perturbation of some enzymes. The effects of ingested phytoecdysteroids in the leek moth, *Acrolepiopsis assectella* Zell.
