Abstract

We derive formulae for neutrino masses and mixing angles in a type I seesaw framework with an underlying $A_4$ flavor symmetry. In particular, the Majorana neutrino mass matrix includes contributions from an $A_4$ triplet, 1, $1'$, and $1''$ flavon fields. Using these formulae, we constrain the general $A_4$ parameter space using the updated global fits on neutrino mixing angles and mass squared differences, including results from the Daya Bay and RENO experiments, and we find predictive relations among the mixing parameters for certain choices of the triplet vacuum expectation value. In the normal hierarchy case, sizable deviation from maximal atmospheric mixing is predicted, and such deviation is strongly correlated with the value of $\theta_{13}$ in the range of $\sim (8-10)^\circ$. On the other hand, such deviation is negligible and insensitive to $\theta_{13}$ in the inverted mass hierarchy case. We also show expectations for the Dirac CP phase resulting from the parameter scan. Future refined measurements of neutrino mixing angles will test these predicted correlations and potentially show evidence for particular triplet vev patterns.
I. INTRODUCTION

With the independent discoveries of a nonzero $\theta_{13}$ from the Daya Bay [1] and RENO [2] collaborations, and the supporting hints from the T2K [3], MINOS [4], and Double Chooz [5] experiments, we now possess the first complete experimental picture of the Pontecorvo-Maki-Nakagawa-Sakata (PMNS) mixing matrix. Following a recent global analysis of neutrino oscillation parameters from Ref. [6] (see also [7–9] and [10–12]), we can summarize the experimental status to date as

$$\sin^2 \theta_{13} = 0.320^{+0.015}_{-0.017},$$ (1)

$$\sin^2 \theta_{23} = \begin{cases} 
0.49^{+0.08}_{-0.05} & \text{(Normal)} \\
0.53^{+0.05}_{-0.07} & \text{(Inverted)}
\end{cases},$$ (2)

$$\sin^2 \theta_{12} = \begin{cases} 
0.026^{+0.003}_{-0.004} & \text{(Normal)} \\
0.027^{+0.003}_{-0.004} & \text{(Inverted)}
\end{cases},$$ (3)

$$\Delta m^2_{21} = 7.62 \pm 0.19 \times 10^{-5} \text{ eV}^2,$$ (4)

$$\Delta m^2_{31} = \begin{cases} 
2.53^{+0.08}_{-0.16} \times 10^{-3} \text{ eV}^2 & \text{(Normal)} \\
-(2.40^{+0.10}_{-0.07}) \times 10^{-3} \text{ eV}^2 & \text{(Inverted)}
\end{cases}. \quad (5)$$

Before the $\theta_{13} \neq 0$ discovery, the PMNS matrix was consistent with the tribimaximal (TBM) mixing pattern [13], which can be written as

$$U_{TBM} = \begin{pmatrix}
\frac{2}{\sqrt{6}} & \frac{1}{\sqrt{3}} & 0 \\
\frac{1}{\sqrt{6}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} \\
\frac{1}{\sqrt{6}} & -\frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}}
\end{pmatrix}, \quad (6)$$

where we have adopted the same phase convention as the PDG [14] for placement of the minus signs. The TBM mixing pattern gives the solar mixing angle corresponding to $\sin^2 \theta_{12} = 1/3$, the atmospheric mixing angle $\sin^2 \theta_{23} = 1/2$, and reactor mixing angle $\sin^2 \theta_{13} = 0$. Neutrino mass matrices that give rise to TBM mixing have distinct invariants that can be traced to discrete symmetries such as the Klein $Z_2 \times Z_2$ group or the symmetry group $S_4$ [15–18] (see also, [19]). On the other hand, by introducing dynamical (flavon) fields, the TBM mixing pattern can arise from a smaller underlying finite group, the tetrahedral group, $A_4$. To be compatible with grand unification, a successful generation of appropriate lepton and quark masses and mixing angles can be achieved by considering $T'$, the double covering group of $A_4$. In an $SU(5)$ grand unified model [20], the $T'$ group also affords a novel origin of $CP$ violation from complex Clebsch-Gordan coefficients [21], while in a Randall-Sundrum model [22, 23], the $T'$ flavor symmetry is simultaneously used to
forbid tree-level flavor-changing neutral currents (FCNCs). For reviews of the status of $A_4$ and $S_4$ models, the tribimaximal and bimaximal paradigm, see [24–26]. For early work in mixing and GUT theories, see [27].

The literature on the interrelation between TBM neutrino mixing matrices and finite group flavor symmetries is vast. With discovery of a nonzero $\theta_{13}$ from Daya Bay and RENO, however, the TBM prediction for a vanishing reactor angle is ruled out, calling into question the entire TBM paradigm. We emphasize, however, that the underlying flavor symmetries that naturally give rise to TBM mixing are nevertheless viable options for explaining the updated PMNS mixing pattern. In particular, we demonstrate that $A_4$, when we include flavons that are not included in the usual TBM analysis, can readily accommodate a large value of $\theta_{13}$ and retain predictivity for $\delta$, the PMNS $CP$-violating Dirac phase.

Work before the Daya Bay and RENO results that focused on finite group symmetries and generating nonzero $\theta_{13}$ includes [28], which studied corrections to TBM from higher dimensional operators and [29], which discussed renormalization group (RG) equations in see-saw models. More recent work looking to use higher dimensional operators to generate violations of the TBM scheme or neutrino phenomenology include [30, 31]. The authors of [32] conclude higher dimension operators and RG effects are equally important for leptogenesis. In [33], it was found that the size of corrections to neutrino mixing sum rules coming from renormalization group running are small. Correspondingly, in [34], it was shown that a large $\theta_{13}$ value cannot be generated through running if $\theta_{13}$ starts at 0. In [35], NLO and NNLO expressions were given for neutrino mixing angles in hierarchal mass scenarios with sequential dominance.

Nevertheless, we note that it is possible, with the so-called Hilbert basis method [36], to construct supersymmetric models where these higher dimensional operators in the holomorphic superpotential vanish. On the other hand, certain flavon-induced corrections in the non-holomorphic Kähler potential [37] cannot be forbidden by any conventional symmetries. Hence, even in the original $A_4$ models where $\theta_{13}$ vanishes at leading order, once these Kähler corrections are properly taken into account, a sizable $\theta_{13}$ can be attained that is compatible with the current experimental value [38].

Much of the recent literature has focused solely on accommodating non-zero $\theta_{13}$ with low-energy perturbations to the TBM matrix and ignore or only briefly discuss the possible underlying UV physics responsible for these deviations. In this vein, one popular parametrization was introduced in [39], which introduced deviations from TBM values using $s$, $a$, and $r$ for the solar, atmospheric, and reactor mixing angles, respectively. Further work along this line, such as parameter scans in
this space of deviations, include [40–48] and also [49,52], which used a similar approach but an
equivalent set of parameters. One drawback of such approaches is that complete UV flavor models
generally predict additional flavor violating effects, which are not captured in these low-energy
deviation studies [53]. Separately, TBM and BM mixing scenarios were studied for the case of
nearly degenerate neutrino masses where loop corrections provide large effects in mixing angles [54].
Loop corrections to the Type I seesaw Majorana neutrino mass matrix leading to nonzero $\theta_{13}$ were
also studied in [55]. Studies of generating nonzero $\theta_{13}$ from breaking $\mu-\tau$ symmetry include [56–58].

In this work, we adopt a top-down approach where we will constrain the UV parameter space
by the low energy neutrino observables. While other $A_4$ studies may have looked at the additional
effects from $1'$ and $1''$ flavons contributing to the Majorana neutrino mass matrix, including [59–65],
they have generally considered the pattern of the vacuum expectation value (VEV) of the triplet
flavon to be $\propto (1,1,1)^T$. Some earlier work has separately considered other forms of the triplet
flavon, such as [66]. In addition, recent literature has focused on small perturbations from the
$(1,1,1)^T$ triplet flavon structure as a mechanism for generating a nonzero $\theta_{13}$ [59,67–69], where
this small perturbation may arise from a vacuum misalignment correction.

In contrast, our work considers the full parameter space of $A_4$ flavons contributing to the
Majorana mass matrix in the Type I seesaw. Thus we consider triplet flavon vevs that are markedly
different from the usual TBM $(1,1,1)^T$ form simultaneously with the presence of $1'$ and $1''$ flavons.
By looking at a completely general admixture of possibly flavon vevs, we can definitively constrain
the entire $A_4$ parameter space in this Type I seesaw model. We remark that for the charged
lepton masses and the Dirac neutrino masses, we introduce the minimal field content to generate
their mass matrices and only introduce the full flavon field content for the RH neutrino masses.
Moreover, even though we consider a larger $A_4$ parameter space than the earlier literature, we still
retain predictivity, especially when the triplet flavon vev pattern preserves a subgroup of $A_4$.

Here we concentrate on the group $A_4$, which is the smallest group that contains a triplet rep-

resentation. Other groups that have been utilized include $O(2)$ and $SO(2)$ symmetry [70], $\Delta(3n^2)$
and $\Delta(6n^2)$ [71,72], $\Delta_{96}$ [73,74], $Q_6$ with three sterile neutrinos [75], and product groups of mod-
ular $Z_n$ finite groups in various permutations [76–85]. Other studies have focused on permutation
symmetry $S_3$ and $S_4$ models [86–92]. Other mixing scenarios beyond TBM and related patterns
include democratic mixing, which has been studied in [43,54,93], tetra-maximal mixing [94], and
anarchic mixing [95–98].

The paper is organized as follows. In Sec. II we briefly review the $A_4$ finite group symmetry
and our type-I seesaw model implementation. In Sec. III we present the results of our parameter
scan of the $A_4$ flavor vev space. We conclude in Sec. [IV] An intermediate step of our calculation is presented in Appendix [A].

II. THE $A_4$ MODEL

We construct a Type I seesaw model based on an $A_4$ flavor symmetry. We include three right-handed neutrinos $N_i$, which are Standard Model gauge singlets. These neutrinos transform as a triplet $3$ under $A_4$. We also assign the lepton $SU(2)$ doublet $L \sim 3$, charged lepton $SU(2)$ singlets $e_R \sim 1$, $\mu_R \sim 1''$, $\tau_R \sim 1'$. To separate the charged lepton coupling scalars from the neutrino coupling scalars, we impose a $Z_2$ symmetry. These representations are summarized in Table I.

| $H$ | $L$ | $N$ | $e_R$ | $\mu_R$ | $\tau_R$ | $\phi_E$ | $\phi_N$ | $\eta$ | $\chi$ | $\psi$ |
|-----|-----|-----|-------|---------|---------|---------|---------|-------|-------|-------|
| $A_4$ | 1 | 3 | 3 | 1 | $1''$ | 1' | 3 | 3 | 1 | 1' | 1'' |
| $Z_2$ | 1 | 1 | 1 | -1 | -1 | -1 | 1 | 1 | 1 | 1 | 1 |

TABLE I: The $A_4$ and $Z_2$ charge assignments of the Standard Model fields and $A_4$ flavons.

The Lagrangian for the leptons is

$$\mathcal{L} \supset (H L (\lambda_e e_R + \lambda_\mu \mu_R + \lambda_\tau \tau_R) \left( \frac{\phi_E}{\Lambda} \right) + \lambda_N \tilde{H} \tilde{L} N + \text{h.c.})$$

$$+ \lambda_{RR} N^T N \left( \frac{c_N \phi_N + c_\eta \eta + c_\chi \chi + c_\psi \psi}{\Lambda} \right) + \text{c.c.},$$

where $\phi_E \sim 3$, $\phi_N \sim 3$, $\eta \sim 1$, $\chi \sim 1'$, and $\psi \sim 1''$ are scalar fields which acquire vevs and break the $A_4$ symmetry at the scale $\Lambda$, and the couplings $c_N$, $c_\eta$, $c_\chi$, and $c_\psi$ are complex. However, we absorb all phases (including Majorana phases) into $c_N$ and thus $c_N$ is indexed to be non-universal. We will not specify here the scalar potential to give the $\phi_E$, $\phi_N$, $\eta$, $\chi$, and $\psi$ fields vevs, but instead we leave a study of the potential construction and vacuum alignment questions for future work.

The Lagrangian includes the familiar Dirac masses for the charged leptons, new Dirac masses for the neutrinos, and a general $A_4$–invariant Majorana mass matrix which includes all possible $A_4$ contractions. Thus, in contrast with early, pre-Daya Bay and RENO models that generated exact TBM mixing by including only the $\phi_N \sim (1, 1, 1)^T$ and $\eta$ flavons, we include the $\chi$ and $\psi$ flavons and allow $\phi_N$ vev to be less constrained: subcategories of our approach have also been considered previously [59–65].

The explicit form of the resulting mass matrices for the charged leptons and neutrinos is easily obtained from the $A_4$ invariants, which are reviewed, for example, in Ref. [24]. We assume $\phi_E$ acquires a vev $\langle \phi_E \rangle = \Lambda (1, 0, 0)^T$, and thus after electroweak symmetry breaking whereby the
Higgs acquires a vev $v_h$, the charged lepton mass matrix is

$$\bar{L}M_L e = \bar{L}v_h \begin{pmatrix} \lambda_e & 0 & 0 \\ 0 & \lambda_\mu & 0 \\ 0 & 0 & \lambda_\tau \end{pmatrix} e, \quad (8)$$

where $e = (e_R, \mu_R, \tau_R)$. The corresponding Dirac mass matrix for the neutrinos is simply governed by the $A_4$ contraction of $L$ and $N$, giving

$$\lambda_N \bar{H} \bar{L} N = \bar{L}M_{DC} N = \bar{L} \begin{pmatrix} \lambda_N v_h & 0 & 0 \\ 0 & 0 & \lambda_N v_h \\ 0 & \lambda_N v_h & 0 \end{pmatrix} N. \quad (9)$$

For the Majorana mass matrix, we will be more general and allow $\phi_N$ to obtain a general vev pattern, $c_N \langle \phi_N \rangle = \Lambda(\phi_a, \phi_b, \phi_c)$. In addition, we let $c_\eta \langle \eta \rangle = \Lambda_\eta$, and similarly for $\chi$ and $\psi$, such that the vev parameters $\eta$, $\chi$, and $\psi$ are dimensionless and have absorbed their respective Lagrangian couplings. We have the Majorana mass matrix

$$M_N N^T N = \Lambda_{RR} N^T N \begin{pmatrix} \frac{2}{3} \phi_a + \eta & -\frac{1}{3} \phi_c + \psi & -\frac{1}{3} \phi_b + \chi \\ -\frac{1}{3} \phi_c + \psi & \frac{2}{3} \phi_b + \chi & -\frac{1}{3} \phi_a + \eta \\ -\frac{1}{3} \phi_b + \chi & -\frac{1}{3} \phi_a + \eta & \frac{2}{3} \phi_c + \psi \end{pmatrix}. \quad (10)$$

It is worth noting that there is another term one could write, $m_{RR} N^T N$, which sets an additional mass scale $m_{RR}$ which we will designate as $\Lambda_{RR}$. We absorb this term into the vev of $\eta$. Since $N$ is a gauge singlet, there is no connection between the Higgs vev and the mass scale $\Lambda_{RR}$. In particular, if we set $\Lambda_{RR} \sim \mathcal{O}(\Lambda_{GUT}) \approx 10^{16}$ GeV, we exercise the seesaw mechanism to generate light neutrino masses. Moreover, we assume the $A_4$ breaking scale $\Lambda \sim 0.1 \Lambda_{RR}$ to avoid tuning issues between the mass scale and the breaking scale. The block matrix for the neutrinos in the $(\nu_L, N)^T$ basis is

$$M_\nu = \begin{pmatrix} 0 & M_{DC}^T \\ M_{DC} & M_N \end{pmatrix}, \quad (11)$$

which generates the effective neutrino mass matrix

$$M_{\nu, \text{eff}} = M_{DC} M_N^{-1} M_{DC}^T, \quad (12)$$

after the right-handed neutrinos have been integrated out.

Now, in exact analogy with the Cabibbo-Kobayashi-Maskawa (CKM) matrix, the PMNS matrix arises when we express the weak charged current interactions in the lepton mass basis. The PMNS
The PMNS matrix is

\[ V_{PMNS} = U_L U^\dagger_\nu, \]  

where

\[ M_L^{\text{diag}} = U_L M_L U^\dagger_L, \quad M_\nu^{\text{diag}} = U_\nu M_\nu,_{\text{eff}} U^\dagger_\nu, \]  

but from Eq. (8), \( U_L = \mathbf{1}_3 \), and thus the PMNS matrix is identified with the neutrino diagonalization matrix \( U^\dagger_\nu \). The three parameters \( \lambda_e, \lambda_\mu, \) and \( \lambda_\tau \), which are each rescaled by \( \langle \phi_E \rangle / \Lambda \), are in one-to-one correspondence with the three charged lepton masses and are hence fixed.

Having identified \( V_{PMNS} \equiv U^\dagger_\nu \), we adopt the standard parametrization of the PMNS matrix given by

\[
V_{PMNS} = \begin{pmatrix}
1 & 0 & 0 \\
0 & c_{23} & s_{23} \\
0 & -s_{23} & c_{23}
\end{pmatrix}
\begin{pmatrix}
c_{13} & 0 & s_{13} e^{-i\delta} \\
0 & 1 & 0 \\
-s_{13} e^{i\delta} & 0 & c_{13}
\end{pmatrix}
\begin{pmatrix}
c_{12} & s_{12} & 0 \\
-s_{12} & c_{12} & 0 \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
1 & e^{i\xi_1} & e^{i\xi_2}
\end{pmatrix},
\]

where \( c_{ij} = \cos \theta_{ij}, \ s_{ij} = \sin \theta_{ij}, \) \( \delta \) is the Dirac phase, \( \xi_1 \) and \( \xi_2 \) are the Majorana phases, with \( 0 \leq \theta_{ij} \leq \pi/2, \ 0 \leq \delta, \ \xi_1, \xi_2 \leq 2\pi \).

We now have a solvable system of equations relating the neutrino masses, mixing angles, and phases with the flavon vevs. From Eq. (12), Eq. (14), and using \( U^\dagger_\nu = V_{PMNS} \), we find the relation

\[
M_D c M_N^{-1} M_D^T = M_{\nu,\text{eff}} = U^\dagger_\nu M^{\text{diag}}_\nu U_\nu = V_{PMNS} M^{\text{diag}}_\nu V^\dagger_{PMNS},
\]

where \( M_N \) is given in Eq. (10). Solving for \( M_N^{-1} \) and inverting, we get

\[
M_N = M_D^T V_{PMNS} (M^{\text{diag}}_\nu)^{-1} V^\dagger_{PMNS} M_D.
\]

Entry by entry, we have a system of six equations that can be solved analytically, which gives exact relations between the \( A_4 \) parameter space and the physical masses and PMNS mixing angles. This is manifestly symmetric, which is most easily seen from Eq. (10). A similar result using the mass entries of the Majorana mass matrix instead of the triplet and one-dimensional flavon vevs was the starting point of [64]. Our approach, in contrast, directly shows the correlation between different UV triplet flavons and low energy neutrino observables.

Naively, we have a six-dimensional UV parameter space, given by the three components of the \( \phi_N \) triplet flavon and each of the one-dimensional flavons. The flavon breaking scale \( \Lambda \) and the Majorana mass scale are unobservable and can be absorbed into the six flavon vev components.
Now, although the triplet’s vevs can be independent degrees of freedom, certain breaking alignments in flavon space preserve the $Z_2$ or $Z_3$ subgroups of $A_4$ and thus reduce the number of UV parameters. We will thus categorize our results according to subgroup preserving and subgroup breaking triplet vev patterns, which are listed in Table II. Subgroup preserving vev patterns thus effectively have a four-dimensional parameter space, while subgroup breaking vev patterns have a six-dimensional space.

In general, there are nine physical parameters which give rise to eight physical predictions: three mixing angles, three masses, and one Dirac CP phase, as well as two Majorana phases that combine to dictate the rate of neutrinoless double $\beta$ decay. We will not discuss $0\nu2\beta$ further in this paper, and instead focus on the three angles, three masses, and the Dirac CP phase. We can thus see both our subgroup preserving and subgroup breaking categories are predictive: the four parameters in the subgroup preserving category, for instance, are over-constrained by the existing neutrino measurements, and the existence of a nontrivial solution reflects the suitability of the $A_4$ finite group as a possible flavor symmetry of the lepton sector. In addition, for both categories, the yet-to-be-discovered Dirac CP phase is predicted from our parameter scan, which we detail in the next section.

### A. Breaking Bimaximality, Analytic Results

We present an analytic understanding of breaking bimaximality (*i.e.* deviations of $\theta_{23}$ from 45°) in our general Type I seesaw $A_4$ construction. First, we calculate the effective neutrino mass matrix, and then analyze to the extent a $\theta_{23} = 45^\circ$ rotation diagonalizes this matrix. Starting with Eq. (9), we write

\[
M_{Dc} = M_{Dc}^T = \lambda_{Nv_h} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix},
\] (18)

| Subgroup | vev alignment |
|----------|---------------|
| $Z_2$    | $(1,0,0), (0,1,0), (0,0,1)$ |
| $Z_3$    | $(-1,1,1), (1,1,-1), (1,-1,1), (1,1,1)$ |
| breaking | $(0,1,1), (1,0,1), (1,1,0), (0,1,-1), (2,1,1), (1,1,2), (1,2,1), (1,-2,1), (1,1,-2), (1,2,1)$ |

TABLE II: Listed vev alignments for $\phi$ that preserve a $Z_2$ or $Z_3$ subgroup of $A_4$. 
Thus, the seesaw mass matrix in Eq. (12) can be inverted to give

\[
(M^\text{diag}_\nu)^{-1} = (U_\nu M_{\nu, \text{eff}} U^{\dagger}_\nu)^{-1} = (U^{\dagger}_\nu)^{-1}(M_{\nu, \text{eff}})^{-1}(U_\nu)^{-1} = U_\nu (M_{\nu, \text{eff}})^{-1} U^{\dagger}_\nu. \tag{19}
\]

Thus, the seesaw mass matrix in Eq. (12) can be inverted to give

\[
M^{-1}_{\nu, \text{eff}} = \frac{1}{\lambda_N^4 v_h^4} M_{\text{DC}} M_N M^T_{\text{DC}}. \tag{20}
\]

Recall that because our charged lepton mass matrix in Eq. (8) is diagonal, we have the identity

\[V_{PMNS} = U^\dagger_\nu,\]

so the diagonalization matrix of \(M_{\nu, \text{eff}}\), and by extension, \(M^{-1}_{\nu, \text{eff}}\) is the PMNS matrix.

Recall that the PMNS matrix is composed of three Jacobi rotation angles, ordered as a \(\theta_{23}\) rotation, a \(\theta_{13}\) rotation, and then a \(\theta_{12}\) rotation, and the phase rotations, as we can see from Eq. (15).

Also, recall that a Jacobi rotation operates on a \(2 \times 2\) block of the matrix, such as

\[
\begin{pmatrix}
a & b \\ b & c
\end{pmatrix},
\]

where the rotation angle is defined as

\[
\tan 2\theta = \frac{2b}{c - a}. \tag{22}
\]

In particular, for fixed \(c\) and \(a\), the sign of \(b\) determines the sign of \(\theta\). Moreover, we know that a rotation matrix for a single angle \(\alpha + \beta\) can be decomposed into first rotating by \(\alpha\) and then by \(\beta\).

(This, of course, does not commute with rotations about other axes.) Hence, we can rotate \(M^{-1}_{\nu, \text{eff}}\) by \(\theta_{23} = 45^\circ\) and then understand deviations from bimaximality by testing the remaining presence of off-diagonal entries in the \((3, 2)\) and \((2, 3)\) entries of the effective neutrino mass matrix.

From Eq. (9) and Eq. (10), the RHS of Eq. (20) is

\[
M^{-1}_{\nu, \text{eff}} = \frac{1}{\lambda_N^2 v_h^2} \begin{pmatrix}
\frac{2}{3} \phi_a + \eta & -\frac{1}{3} \phi_b + \chi & -\frac{1}{3} \phi_c + \psi \\
-\frac{1}{3} \phi_b + \chi & \frac{2}{3} \phi_c + \psi & -\frac{1}{3} \phi_a + \eta \\
-\frac{1}{3} \phi_c + \psi & -\frac{1}{3} \phi_a + \eta & \frac{2}{3} \phi_b + \chi
\end{pmatrix}, \tag{23}
\]

which as a trivial check, is still symmetric. After we perform the \(\theta_{23} = 45^\circ\) bimaximal rotation, we have

\[
R^T_{BM} M^{-1}_{\nu, \text{eff}} R_{BM} =
\begin{pmatrix}
\frac{2}{3} \phi_a + \eta & \frac{1}{3\sqrt{2}}(-\phi_b + \phi_c) + \frac{1}{\sqrt{2}}(\chi - \psi) & -\frac{1}{3\sqrt{2}}(\phi_b + \phi_c) + \frac{1}{\sqrt{2}}(\chi + \psi) \\
\frac{1}{3\sqrt{2}}(-\phi_b + \phi_c) + \frac{1}{\sqrt{2}}(\chi - \psi) & \frac{1}{3}(\phi_a + \phi_b + \phi_c) - \eta + \frac{1}{2} \chi + \frac{1}{2} \psi & \frac{1}{3}(-\phi_b + \phi_c) - \frac{1}{2} \chi + \frac{1}{2} \psi \\
\frac{1}{3\sqrt{2}}(-\phi_b + \phi_c) + \frac{1}{\sqrt{2}}(\chi + \psi) & \frac{1}{3}(\phi_a + \phi_b + \phi_c) - \eta + \frac{1}{2} \chi + \frac{1}{2} \psi & \frac{1}{3}(-\phi_a + \phi_b + \phi_c) + \eta + \frac{1}{2} \chi + \frac{1}{2} \psi
\end{pmatrix}. \tag{24}
\]
So, if $\frac{1}{3}(-\phi_b + \phi_c) - \frac{1}{2}\chi + \frac{1}{2}\psi \neq 0$, then the $\theta_{23} = 45^\circ$ bimaximal rotation was insufficient to eliminate the (3, 2) and (2, 3) entries and an additional $\theta_{23}$ rotation is needed. (In addition, if the (2, 2) and (3, 3) entries are identical, then $\theta_{23} = 45^\circ$ is guaranteed.) Moreover, we see that the transformation $\phi_b \leftrightarrow \phi_c$ and $\chi \leftrightarrow \psi$ changes the sign of the (3, 2) and (2, 3) entries while leaving the (2, 2) and (3, 3) entries fixed. Hence, we can see that any viable solution characterized by a triplet vev of $(\phi_a, \phi_b, \phi_c)$ and a particular set of $\eta$, $\chi$, and $\psi$ can be transmuted to a different solution characterized by $(\phi_a, \phi_c, \phi_b)$ and $\eta$, $\psi$, and $\chi$ with an opposite sign of the deviation from $\theta_{23} = 45^\circ$.

III. PARAMETER SCAN RESULTS FOR SUBGROUP PRESERVING AND SUBGROUP BREAKING TRIPLET FLAVON VEVS

Since current neutrino experiments do not have sensitivity to individual neutrino masses, we constrain the low energy neutrino observables by fitting to three mixing angles, two $\Delta m^2$, and the cosmological constraint on the sum of absolute neutrino masses. Clearly, the remaining parameter space for $\delta$ is the predictive relation from our parameter scan. (As stated before, we do not discuss the sensitivity to the Majorana phases from neutrino-less double $\beta$ decay experiments.) We first take the system of equations in Eq. (17) and solve for the $A_4$ breaking vevs in terms of the neutrino observables. These solutions are presented in Appendix A. Since we want to work from the top-down, however, we partially invert the system to solve for the neutrino masses and the $A_4$ singlet vevs in terms of the $A_4$ triplet vev and the neutrino mixing angles and the $CP$ phase. We obtain

$$m_i = \frac{v_h^2}{\Lambda_{RR}} (a^i b^j c^k \epsilon_{ijk} (\phi_a b^j c^k \epsilon_{ijk} + \phi_b a^i c^k \epsilon_{ijk} + \phi_c a^i b^j \epsilon_{ijk})^{-1},$$

where $m_1, m_2, m_3$ are the three light neutrino masses, $i, j, k = 1, 2, 3$, and $\epsilon_{ijk}$ is the Levi-Civita tensor. The three-component vectors $\vec{a}$, $\vec{b}$, $\vec{c}$ are found in Table III.

This partial inversion is advantageous because, using the measured mixing angles, we can test individual $A_4$ triplet vevs and determine the fit to the correct mass squared differences and the cosmological constraint. We reparametrize the mass squared difference constraints into a ratio $\Delta_{21}/\Delta_{31}$, where $\Delta_{ij} \equiv m_i^2 - m_j^2$ and use the dimensionless ratio to constrain the dimensionless vevs in Eq. (25). The mass scale $v_h^2/\Lambda_{RR}$ is then fixed by matching either of the measured mass squared differences.

In line with our top-down approach and intuition about the $A_4$ finite group, we attempt to preserve many of the symmetries present in the case of TBM mixing. Yet, simply relaxing $\sin^2 \theta_{13} = 0$
while simultaneously keeping the other TBM mixing angle relations did not lead to viable solutions without perturbing the triplet vev alignment. We therefore choose to relax the bimaximal relation \( \sin^2 \theta_{23} = \frac{1}{2} \) and maintain the trimaximal relation \( \sin^2 \theta_{12} = \frac{1}{3} \). In this way, we can understand a larger region of \( A_4 \) parameter space since the experimental bounds on \( \theta_{12} \) are tighter than those on \( \theta_{23} \). Given this fixed \( \theta_{12} \), we then choose each of the Dirac and Majorana phases to be 0 or \( \pi \) for each triplet vev pattern.

However, this process itself is not entirely trivial, as not all choices are independent. Up to field re-phasing, there are four transformations about bimaximal mixing in which components of Eq. (25) transform antisymmetrically. Under the interchange of \( \theta_{23} = 45^\circ + x \leftrightarrow \theta_{23} = 45^\circ - x \) and any of the four,

\[
\begin{align*}
\delta = 0, \xi_1 = 0, \xi_2 = 0 & \leftrightarrow \delta = \pi, \xi_1 = \pi, \xi_2 = \pi \\
\delta = 0, \xi_1 = \pi, \xi_2 = 0 & \leftrightarrow \delta = \pi, \xi_1 = \pi, \xi_2 = 0 \\
\delta = 0, \xi_1 = 0, \xi_2 = \pi & \leftrightarrow \delta = \pi, \xi_1 = 0, \xi_2 = \pi \\
\delta = 0, \xi_1 = \pi, \xi_2 = \pi & \leftrightarrow \delta = \pi, \xi_1 = 0, \xi_2 = 0,
\end{align*}
\]

we find

\[
\begin{align*}
\vec{a} \cdot (\vec{b} \times \vec{c}) & \leftrightarrow -\vec{a} \cdot (\vec{b} \times \vec{c}) \\
\vec{b} \times \vec{c} & \leftrightarrow \vec{c} \times \vec{b} \\
\vec{a} \times \vec{b} & \leftrightarrow \vec{a} \times \vec{c}.
\end{align*}
\]

It immediately follows that the existence of one solution implies there is a corresponding solution with different phases (and a possibly different triplet alignment) which is related under these

\[\text{TABLE III: The explicit components of } \vec{a}, \vec{b}, \vec{c} \text{ as function of mixing angles and the triplet } \phi.\]
transformations. What remains to be specified are the angles $\theta_{23}$ and $\theta_{13}$, which we scan over the $2\sigma \theta_{23}$ range of Ref. [12] and over the $2\sigma \theta_{13}$ experimental bounds from Daya Bay in Ref. [1]. We draw contours in this two-dimensional plane that satisfy the measured mass squared differences from Ref. [12] and we constrain the ratio of $\Delta m^2$ within $2\sigma$ uncertainties as dictated by the predicted neutrino hierarchy and set the individual neutrino mass scale using $\Lambda_{RR}$. From the existence of matter effects in solar neutrino oscillation, we know that $\Delta_{21} > 0$. So by enforcing this constrain upon the ratio there is a unique positive value and negative value for $\Delta_{21}/\Delta_{31}$ that correspond to a normal or inverted neutrino mass hierarchy respectively. We then require the contours to satisfy the $\sum_i |m_{\nu_i}| < 0.81$ eV [99]. Because degenerate neutrino spectra lead to numerically unstable results, we discard possible solutions arising from degenerate neutrino spectra.

A. Numerical Results

These results are shown in the left panel of Fig. 1 for subgroup preserving triplet vev patterns from Table II that generate a normal hierarchy, while the right panel shows the subgroup preserving patterns that generate an inverted hierarchy. These figures clearly show the correlations between the deviation from the bimaximal $\theta_{23}$ and nonzero $\theta_{13}$. Patterns that have such solutions are now uniquely determined and predict a very specific combination of masses and the $CP$ phase. A notably absent alignment is the (1,1,1) breaking pattern, often associated with TBM mixing. We can understand this by considering Eq. (20) and asserting $\phi_a = \phi_b = \phi_c$. We find

$$f(\theta_{12}, \theta_{13}, \theta_{23})(m_2 - m_3) = 0,$$

and so unless the function $f$ is zero, the masses $m_2$ and $m_3$ are required to be degenerate and this vev is not a viable phenomenological alignment. Under exact TBM mixing, $f$ is zero and the masses are free.

We also show the corresponding parameter scans for subgroup breaking triplet vev patterns that give normal hierarchies in the left panel of Fig. 2 and inverted hierarchies in the right panel. Although the parameter space is less predictive, we can nevertheless see that a normal hierarchy requires significant breaking of bimaximality, while an inverted hierarchy still allows for a bimaximal $\theta_{23}$ for some vev patterns.

For each successful triplet vev pattern and phase choice, we list the $\theta_{23}$ value and neutrino mass spectrum corresponding to the central value for $\theta_{13}$ from the Daya Bay collaboration in Table IV.
FIG. 1: Contour plots of $\Delta_{21}/\Delta_{41}$ over the $2\sigma$ regions of $\theta_{23}$ and $\theta_{13}$ for subgroup preserving triplet vev patterns that generate (left panel) a normal hierarchy and (right panel) an inverted hierarchy. For normal hierarchies, we find the $(1, 0, 0)$ pattern stays close to the central angle of $\theta_{23}$, while the the $(1, -1, 1)$ and $(1, 1, -1)$ patterns avoid the central value. The inverted hierarchy solutions, however, only deviate from the maximal angle of $\theta_{23}$ by values of order $O(0.1^\circ)$.

FIG. 2: Contour plots of $\Delta_{21}/\Delta_{41}$ over the $2\sigma$ regions of $\theta_{23}$ and $\theta_{13}$ for subgroup breaking triplet vev patterns that generate (left panel) a normal hierarchy and (right panel) an inverted hierarchy. The normal hierarchy solutions characteristically avoid the central value of $\theta_{23}$. Like the subgroup preserving vev patterns, here the inverted hierarchy solutions feature little deviations from the central value of $\theta_{23}$.

The vev alignments $(1, 0, 0)$ and the permutations of $(-1, 1, 1)$ comprising the first and second sets of solutions shown in Table IV are vevs preserving the $Z_3$ and $Z_2$ subgroups, respectively. The remaining vev alignments break $A_4$ completely. Each vev alignment can produce some deviation from $\theta_{23} = \pi/4$, and most notably, non-$Z_3$ preserving alignments can produce significant breaking of bimaximality where TBM cannot be approximate.
Generally, we find that inverted hierarchies feature deviations from $\theta_{23}$ from the TBM case of order $O(0.1^\circ)$, while normal hierarchies favor deviations an order of magnitude larger. For a given choice of Dirac $CP$ phase, we find that most breaking patterns are relatively insensitive to changes in $\theta_{13}$ with the current experimental bounds. We also highlight the fact that many simple $A_4$ triplet vev possibilities are excluded by the current experimental data. In particular, arbitrary triplet vev patterns in general will not generate the small hierarchy in experimental mass squared differences, and those that do are highly predictive about the extent of bimaximal breaking.

We can semi-analytically see why the normal hierarchy solutions deviate more strongly from bimaximality than the inverted hierarchy solutions. In general, for fixed $\theta_{12}$ and $\theta_{13}$, we can consider a Taylor expansion of the neutrino masses around $z \equiv \theta_{23} - 45^\circ$,

$$
m_1 = x_1 + y_1 z + \ldots ,
$$

$$
m_2 = x_2 + y_2 z + \ldots ,
$$

$$
m_3 = x_3 + y_3 z + \ldots ,
$$

where $x_{1,2,3}$ and $y_{1,2,3}$ are the zeroth and first order coefficients. Using this expansion, we have

$$
\Delta_{21} = m_2^2 - m_1^2 \approx x_2^2 - x_1^2 + 2(x_2 y_2 - x_1 y_1) z + O(z^2).
$$

A complete expression of this mass squared difference for the central values of $\theta_{12}$ and $\theta_{13}$ and arbitrary triplet vev is not useful, but if we consider the special case of $\phi_b = \phi_c$, we generally find $x_1 = x_2$ and $y_1 = -y_2$, giving

$$
\Delta_{21} \approx 4x_2 y_2 z + O(z^2).
$$

Furthermore, if we consider the behavior of the expansion coefficients $x_1$ and $y_1$ for normal hierarchy solutions versus related inverted hierarchy solutions, we find $x_1^{(N)} \approx x_1^{(I)}$ and $4y_1^{(N)} \approx y_1^{(I)}$: from the $\Delta_{21}$ constraint, we see

$$
z^{(N)} \approx 4z^{(I)},
$$

which implies that the resulting deviation from bimaximality is much larger for normal hierarchies compared to inverted hierarchies. When exact expressions are used, the difference can be as big as an order of magnitude, as evident in the figures.

**B. Dirac $CP$ Phase Predictions**

We now examine the predicted Dirac $CP$ phase for various triplet vev patterns. Instead of fixing $\delta$ and scanning over $\theta_{23}$ and $\theta_{13}$ as before, we now set $\theta_{23}$ to the value preferred by the central
\(\theta_{13}\) value of Daya Bay \[1\], as shown in Table II. and scan this \(\theta_{23}\) slice of the \(\delta\) vs. \(\theta_{13}\) plane. Contours that satisfy the correct mass squared differences are highlighted and shown in Fig. 3 for a few illustrative choices of vev patterns. Thus, for \(\theta_{13}\) within the 2\(\sigma\) range of \[1\], the favored range of \(\delta\) can be broad, as for the \((1, 1, -2)\) vev, or fairly narrow, as for the \((1, 1, -1)\), \((-1, 1, 1)\) and \((0, 1, 1)\) vevs. This figure shows that a measurement of \(\delta\) and further refinement in narrowing the \(\theta_{13}\) uncertainties can exclude or significantly favor a particular set of \(A_4\) vev patterns. In addition, we see that shifts in the central value of \(\theta_{13}\) will serve to disfavor particular vev patterns as well as better accommodate other vev patterns. Certainly, more data is needed to test these possibilities and the \(A_4\) paradigm.

**TABLE IV:** The collection of vev alignments considered in our parameter scan, resulting hierarchy, phases, deviation from bimaximality, and neutrino masses. The mass hierarchy column indicates whether the vev generates a normal (N) hierarchy or inverted (I) hierarchy. The last two columns indicate the required phases to obtain a valid mass hierarchy and the \(\theta_{23}\) angle and neutrino masses corresponding to the central \(\theta_{13}\) value from Daya Bay \[1\].
FIG. 3: Contours for various $A_4$ breaking patterns at their respective favored $\theta_{23}$ angle based on Table IV. The $(1, 1, -1)$ and $(1, 1, -2)$ patterns show the ratio contour for a normal mass hierarchy, while the $(-1, 1, 1)$ and $(0, 1, 1)$ show the ratio for an inverted mass hierarchy. The $(1, 1, -1)$, $(-1, 1, 1)$, and $(0, 1, 1)$ vevs are moderately more predictive of $\delta$ than the $(-1, 1, 1)$ vev.

IV. CONCLUSIONS

In light of the results from the Daya Bay and RENO collaborations, we have developed a framework for understanding the constraints on the $A_4$ parameter space from low energy neutrino observables. For our parameter scan, we have assumed a Type I seesaw model with a minimal $A_4$ flavor structure governing the charged lepton masses and the Dirac neutrino masses, but the Majorana mass matrix has contributions from each of the possible $3$, $1$, $1'$, and $1''$ flavons, where the triplet vev pattern is initially unconstrained. We categorize the triplet vev according to $Z_3$ or $Z_2$ subgroup preserving patterns, which enhances the model predictivity: for these subgroup preserving patterns, four $A_4$ parameters are used to predict seven neutrino observables. Regarding the chosen vev patterns, we leave the question of scalar potentials or vacuum alignment for future work.
We have analyzed the $A_4$ parameter space in two distinct and intriguing slices. In the first case, we fix $\theta_{12}$ to be trimaximal and scan over the resulting $\theta_{23}$ vs. $\theta_{13}$ plane for various choices of Dirac and Majorana phases. The results show that vev patterns giving a normal neutrino mass hierarchy have moderately large breaking of bimaximality for $\theta_{23}$, while inverted hierarchies generally retain bimaximality as a prediction. This indicates that a non-bimaximal $\theta_{23}$ measurement, such as the preliminary result $\sin^2(2\theta_{23}) = 0.94^{+0.04}_{-0.05}$ from MINOS [100] is favorably correlated with a normal hierarchy in our $A_4$ framework. We also analyzed the predictions for the Dirac $CP$ phase $\delta$ for some illustrative choices of triplet vev pattern in the $\delta$ vs. $\theta_{13}$ plane. This analysis emphasizes the point that a future measurement of $\delta$, decreased uncertainty in $\theta_{13}$, and shifts in the central value of $\theta_{13}$ can strongly favor or exclude particular triplet vev patterns, highlighting the fact that future experimental results have significant power in discriminating possible $A_4$ flavon structures.

Appendix A: General VEV Solutions of Flavon Fields

In Eq. [17], we have six equations that relate the $A_4$ flavons comprising the Majorana mass matrix to the low energy neutrino masses, mixing angles, and phases. We can solve this system to express the triplet flavon components, $(\phi_a, \phi_b, \phi_c)^T$, and the one-dimensional flavons, $\eta$, $\chi$, and $\psi$,
in terms of the physical neutrino observables. This solution set is

\[ \langle \phi_a \rangle = F \left( \frac{1}{m_1} \left[ c_{12}^2 s_{13}^2 - (s_{12}s_{23} - e^{-i\delta} c_{12} c_{23} s_{13}) (c_{23}s_{12} - e^{i\delta} c_{12}s_{13}s_{23}) \right] 
+ \frac{1}{m_2} e^{-i\xi_1} \left[ s_{13}^2 s_{12} + (c_{12}s_{23} - e^{-i\delta} c_{23}s_{12}s_{13}) (c_{12}s_{23} - e^{i\delta} s_{12}s_{13}s_{23}) \right] 
+ \frac{1}{m_3} e^{-i\xi_2}(s_{13}^2 - c_{13}^2c_{23}s_{23}) \right), \quad (A1) \]

\[ \langle \phi_b \rangle = F \left( \frac{1}{m_1} \left[ (s_{12}s_{23} - e^{-i\delta} c_{12}c_{23}s_{13}) (s_{12}s_{23} - e^{i\delta} c_{12}c_{23}s_{13}) + c_{12} c_{13} (c_{23}s_{12} + e^{-i\delta} c_{12}s_{13}s_{23}) \right] 
+ \frac{1}{m_2} e^{-i\xi_1} \left[ (c_{12}s_{23} + e^{-i\delta} c_{23}s_{12}s_{13})(c_{12}s_{23} + e^{i\delta} c_{23}s_{12}s_{13}) - c_{13}s_{12}(c_{12}s_{23} - e^{-i\delta} s_{12}s_{13}s_{23}) \right] 
+ \frac{1}{m_3} e^{-i\xi_2}(c_{13}^2 c_{23} - e^{-i\delta} c_{13}s_{13}s_{23}) \right), \quad (A2) \]

\[ \langle \phi_c \rangle = F \left( \frac{1}{m_1} \left[ c_{12} c_{13} (-s_{12}s_{23} + e^{-i\delta} c_{12}c_{23}s_{13}) + (c_{23}s_{12} + e^{i\delta} c_{12}s_{13}s_{23}) (c_{23}s_{12} + e^{-i\delta} c_{12}s_{13}s_{23}) \right] 
+ \frac{1}{m_2} e^{-i\xi_1} \left[ c_{13}s_{12}(c_{12}s_{23} + e^{-i\delta} c_{23}s_{12}s_{13}) + (c_{12}s_{23} - e^{i\delta} s_{12}s_{13}s_{23}) (c_{12}s_{23} - e^{-i\delta} s_{12}s_{13}s_{23}) \right]

+ \frac{1}{m_3} e^{-i\xi_2}[c_{13}c_{12}^2 + 2e^{-i\delta} s_{13}c_{23}] \right), \quad (A6) \]

where \( F = \frac{v_H^2 \lambda_3^2}{A_{RR}} \). We invert Eq. (A1), Eq. (A2), and Eq. (A3) to solve for the neutrino masses in terms of the triplet vev components \((\phi_a, \phi_b, \phi_c)^T\). Then, we constrain the one-dimensional flavons and the neutrino masses by assuming a particular triplet vev pattern and scanning over the mixing angles and phases, applying the constraint on mass squared differences from [12] and
the cosmological bound on the sum of absolute neutrino masses from [14].
