1. Introduction

Ferroelectric superlattices comprising two or more different layers have received immense attention due to their potential applications, as well as their striking new or enhanced behaviors (Nakagawara et al., 2000; Dawber et al., 2005). In those structures, the coupling at the interface between the two constituents has been demonstrated to play an important role in governing their properties (Bousquet et al., 2005). Theoretical study of interface coupling in ferroelectric superlattices was initially performed based on the Landau-like formulation by taking the continuum limit of the transverse Ising model (Qu et al., 1997). In their model, the extrapolation lengths describe the inhomogeneity of polarizations near the surfaces and an interface-related parameter gives the strength of the coupling at the interface. We have recently proposed a thermodynamic model with only one unknown parameter to study the effect of interface on polarization behaviours at the interface region between two bulk ferroelectrics (Chew et al., 2003; Tsang et al., 2004). The intrinsic ferroelectric coupling at the interface leads to variation of polarization across the interface of the heterostructures.

In this contribution, we discuss some fundamental properties of the physics of interfaces in ferroelectric heterostructures and superlattices using the Landau-Ginzburg theory. The key issue that will be addressed is how the intrinsic ferroelectric coupling at the interface affects the physical properties of the hybrid structures such as phase transitions, polarization modulation profiles and dielectric susceptibilities. We begin with a discussion for heterostructure of interfaces between a bulk ferroelectrics and dielectrics, in which the influence of thickness is not significant. Explicit expressions describe the spatial profile of polarization at the interface region of the heterostructure are obtained (Chew et al., 2003). The influence of the intrinsic interface coupling on the inhomogeneity and discontinuity or continuity of polarization at the interface is illustrated.

Since ferroelectric superlattice is an interesting system to study the interface effect, the influence of thickness on the polarization profiles of the superlattice is investigated. Analytical expressions of the polarization profile for superlattices are derived and discussed in detailed (Ishibashi et al., 2007; Chew et al., 2009). Explicit expressions for dielectric
susceptibilities in the paraelectric phase of the superlattice are also obtained (Chew et al., 2008). Finally, we apply the model to epitaxial PbTiO$_3$/SrTiO$_3$ by incorporating the depolarization field and lattice strain in the free energy functional. Some calculated results are discussed with experimental data. We conclude the chapter with some remarks.

2. Model of ferroelectric/dielectric heterostructure interfaces

In this section, the essential details for deriving the formalism of the ferroelectric/dielectric heterostructure interface are presented (Chew et al., 2003). We assume a one-dimensional problem in which the polarizations and related physical quantities vary along the $x$-direction perpendicular to the interface of the heterostructure. The total energy associates with the heterostructure can be expressed as

$$F = F_1 + F_2 + F_i,$$

where $F_1$ and $F_2$ are the total free energy density of the ferroelectric constituent $A$ and dielectric constituent $B$, respectively. $F_i$ is the coupling energy at the interface between the two constituents.

The total free energy density of the ferroelectric constituent $A$ and dielectric constituent $B$ are given by

$$\begin{aligned}
F_1 &= \int (f_1 - f_1') dx, \\
F_2 &= \int (f_2 - f_2') dx,
\end{aligned}$$

which extend from $x \to -\infty$ to $x = 0$ and $x = 0$ to $x \to \infty$, respectively. $f_j$ denotes the Landau-Ginzburg free energy densities of constituent layer $j$, whereas $f_j'$ gives the energy density in the single domain state of constituent $j$.

In the present study, the coupling energy $F_i$ between the polarizations at the interface is described as

$$F_i = \frac{\lambda}{2} (p_i - q_i)^2,$$

where $p_i$ and $q_i$ are the interface polarizations at $x = 0$. $\lambda$ is the coupling constant describing the strength of the interaction.

The free energy density of the ferroelectric constituent $A$ with $p^2 = p_b^2 = -\alpha_1 / \beta_1$ in the bulk ($x \to -\infty$) is given by

$$f_1 - f_1' = \frac{\alpha_1}{2} p^2 + \frac{\beta_2}{4} p^4 + \frac{\kappa_1}{2} \left( \frac{dp}{dx} \right)^2 - \left( \frac{\alpha_1}{2} p_b^2 + \frac{\beta_1}{4} p_b^4 \right).$$

For the dielectric constituent $B$, we have $q = q_b = 0$ at $x \to \infty$, and the free energy density contribution from the dielectric constituent (with the higher order $\beta_2 q^4 / 4$ term truncated) is

$$f_2 - f_2' = \frac{\alpha_2}{2} q^2 + \frac{\kappa_2}{2} \left( \frac{dq}{dx} \right)^2,$$
because \( f_2^\prime = 0 \) for a non-polar dielectric. \( p \) and \( q \) are the order parameters of the ferroelectric and dielectric constituents, respectively. \( \alpha_1 \) is a temperature-dependent parameter

\[
\alpha_1 = \alpha_{10} (T - T_0),
\]

(6)

where \( \alpha_{10} > 0 \) is a temperature-independent parameter. \( \alpha_2 > 0, \beta_1 > 0, \kappa_1 > 0 \) and \( \kappa_2 > 0 \) are all temperature-independent coefficients.

The equilibrium states of the heterostructures correspond to the minima of \( F \) with respect to variations of \( p \) and \( q \). These are given by solving the Euler-Lagrange equations for \( p \) and \( q \):

\[
\begin{align*}
\frac{\partial F}{\partial p} - \frac{\partial}{\partial x} \left( \frac{\partial F}{\partial p'} \right) &= 0, \\
\frac{\partial F}{\partial q} - \frac{\partial}{\partial x} \left( \frac{\partial F}{\partial q'} \right) &= 0,
\end{align*}
\]

(7)

with the boundary conditions

\[
\begin{align*}
p &= p_i \quad \text{at} \quad x = 0, \\
q &= q_i
\end{align*}
\]

(8a)

and

\[
\begin{align*}
p &= p_b \quad \text{and} \quad \frac{dp}{dx} = 0 \quad \text{at} \quad x \to -\infty, \\
q &= q_b \quad \text{and} \quad \frac{dq}{dx} = 0 \quad \text{at} \quad x \to +\infty,
\end{align*}
\]

(8b)

where \( p_b \) and \( q_b \) are the bulk polarization of the ferroelectric constituent \( A \) (at \( x = -\infty \)) and the dielectric constituent \( B \) (at \( x = +\infty \)), respectively.

For the present study of ferroelectric/dielectric heterostructure of interface, it turns out that the free energy \( F \) of eq. (1) can be rewritten in terms of the interface polarizations \( p_i \) and \( q_i \) as order parameters. This gives \( F \) as a function of \( p_i \) and \( q_i \) without the usual integral form.

Solving eqs. (1) and (7) simultaneously with the boundary conditions (i.e. eqs. (8a) and (8b)) imposed, and integrating once, the Euler-Lagrange equations becomes,

\[
\frac{\alpha_1}{2} (p^2 - p_i^2) + \frac{\beta_1}{4} (p^2 - p_i^4) + \frac{\kappa_1}{2} \left( \frac{dp}{dx} \right)^2 = 0,
\]

(9)

and

\[
\frac{\alpha_2}{2} q^2 = \frac{\kappa_2}{2} \left( \frac{dq}{dx} \right)^2.
\]

(10)

By solving eq. (9), the polarization of the ferroelectric constituent \( A \) becomes
\[ p = p_b \tanh \frac{K_1}{\sqrt{2}} (x_i - x), \]

where

\[ K_1 = \sqrt{-\frac{\alpha_1}{\kappa_1}}. \]

(12)

For the dielectric constituent \( B \), the solution of eq. (10) gives

\[ q = q_i \exp(-K_2x), \]

with

\[ K_2 = \sqrt{\frac{\alpha_2}{\kappa_2}}. \]

(14)

If \( p_i \) is determined, \( x_i \) can be obtained from eq. (11). In eqs. (11) and (13), the magnitude of the interface polarizations \( p_i \) and \( q_i \) are determined by the interface coupling parameter \( \lambda \).

The total energy, eq. (1), of the heterostructure can be written in terms of \( p_i \) and \( q_i \) as

\[ F = \frac{1}{3} \sqrt{\frac{\beta_i \kappa_1}{2}} (p_i^3 - 3p_i p_b^2 + 2p_b^3) + \frac{\sqrt{\alpha_2 \kappa_2}}{2} q_i^2 + \frac{\lambda}{2} (p_i - q_i)^2. \]

(15)

The equilibrium structure can be found from

\[ \frac{\partial F}{\partial p_i} = \sqrt{\frac{\beta_i \kappa_1}{2}} (p_i^2 - p_b^2) + \lambda (p_i - q_i) = 0, \]

(16)

and

\[ \frac{\partial F}{\partial q_i} = \sqrt{\alpha_2 \kappa_2} q_i - \lambda (p_i - q_i) = 0. \]

(17)

Let us examine the variation of polarization across the interface and the total energy \( F \) of the heterostructure for the particular conditions of \( \lambda = 0 \) and \( \lambda \to \infty \). The variation of polarization across the interface can be examined by looking into the continuity or discontinuity in interface polarizations \( p_i - q_i \). Without interface coupling (\( \lambda = 0 \)), we find that \( p_i = p_b \) and \( q_i = 0 \). Thus, the mismatch of interface polarizations and the total energy of the heterostructure are found to be

\[ p_i - q_i = p_b, \]

(18)

and

\[ F = 0, \]

(19)

respectively.
Intrinsic Interface Coupling in Ferroelectric Heterostructures and Superlattices

For a strong interface coupling, i.e., $\lambda \to \infty$, we have $p_i = q_i$, implying that the polarization is continuous across the interface. In order to find $p_i = q_i$, it is convenient to write eq. (15) in terms of only $p_i$ as

$$F = \frac{1}{3} \sqrt{\frac{\beta_1 \kappa_1}{2}} (p_i^3 - 3p_ip_i^2 + 2p_i^3) + \sqrt{\frac{\alpha_2 \kappa_2}{2}} p_i^2,$$

and by minimizing it, we obtain

$$p_i = q_i = p_b \left\{ \frac{1 + \frac{1}{2} \left( \frac{\alpha_2}{\alpha_1} \right) \left( \frac{\kappa_2}{\kappa_1} \right)}{1 + \frac{1}{2} \left( \frac{\alpha_2}{\alpha_1} \right) \left( \frac{\kappa_2}{\kappa_1} \right) - \frac{1}{2} \left( \frac{\alpha_2}{\alpha_1} \right) \left( \frac{\kappa_2}{\kappa_1} \right)} \right\}, \quad (21)$$

which clearly indicates that the polarizations at the interface are determined by the intermixed properties of two constituents.

Fig. 1. Spatial dependence of polarization at the interface region of ferroelectric/dielectric heterostructures with $\lambda^{-1} = 10$ (top), 1 (middle) and 0 (bottom). In the curves, the parameters are: $\alpha_1 = -1$, $\alpha_2 = 1$, $\beta_1 = 1$, $\kappa_1 = 4$ and $\kappa_2 = 9$. Solid circles denote the polarization at interface.

Figure 1 shows a typical example of a ferroelectric/dielectric heterostructure of interface with different strength of interface coupling $\lambda$. It is seen that the mismatch in the polarization across the interface is notable for a loose coupling at the interface $\lambda^{-1} = 10$. The mismatch in the interface polarization becomes smaller with increasing coupling strength. It is interesting to see that the coupling at the interface induces polarization in the dielectric constituent. This may be called the interface-induced polarization, and it extends into the bulk over a distance governed by the characteristic length of the material $K_2^{-1}$, which is governed by $\alpha_2$ and $\kappa_2$. 
Fig. 2. Mismatch in the polarization at the interface of ferroelectric/dielectric heterostructures as a function of $\lambda^{-1}$. Other parameters are the same as for Fig. 1.

In Fig. 2, the mismatch in polarizations across the interface is examined under various strengths of interfacial coupling. The results clearly show that the mismatch in the interface polarizations is decreased with increasing interface coupling strength.

3. Model of ferroelectric/dielectric superlattices

We now consider a periodic superlattice composed of alternating ferroelectric layer and dielectric layer (ferroelectric/dielectric superlattices), as shown in Fig. 3. Some key points are repeated here for clarity of discussion. Similarly, we assume that all spatial variation of polarization takes place along the x-direction. The thickness of ferroelectric layer and dielectric layer are $L_1$ and $L_2$, respectively. $L$ is the periodic thickness of the superlattice. The two layers are coupled with each other across the interface. Periodic boundary conditions are used for describing the superlattices.

By symmetry, the average energy density of the ferroelectric/dielectric superlattice $F$ is

$Ishibashi & Iwata, 2007; Chew et al., 2008; Chew et al., 2009)$

$$F = \frac{2}{L} (F_1 + F_2 + F_1). \quad (22)$$

Fig. 3. Schematic illustration of a periodic ferroelectric superlattice composed of a ferroelectric and dielectric layers. The thickness of ferroelectric layer $A$ and dielectric layer $B$ are $L_1$ and $L_2$, respectively. $L = L_1 + L_2$ is the periodic thickness of the superlattice.
In eq. (22), the total free energy density of the ferroelectric layer $F_1$ is given by

$$F_1 = \int_0^{L_{1}/2} \left( \frac{\alpha_1}{2} p^2 + \frac{\beta_1}{4} p^4 + \frac{\kappa_1}{2} \left( \frac{dp}{dx} \right)^2 - pE \right) dx ,$$  \(23\)

whereas the total free energy densities of the paraelectric layer $f_2$ is

$$F_2 = \int_{L_{1}/2}^{L_{1}} \left[ \frac{\alpha_2}{2} q^2 + \frac{\kappa_2}{2} \left( \frac{dq}{dx} \right)^2 - qE \right] dx ,$$  \(24\)

respectively. In eqs. (23) and (24), $p$ and $q$ are the order parameters of the ferroelectric layer and paraelectric layer, respectively. $E$ denotes the external electric field.

The coupling energy at the interface between the ferroelectric- and dielectric-layers is as shown in eq. (3). In this case, the boundary conditions at the interface ($x = L_{1}/2$) are described by

$$\begin{cases}
\frac{dp}{dx} = -\frac{\lambda}{\kappa_1} (p_1 - q_1), \\
\frac{dq}{dx} = \frac{\lambda}{\kappa_2} (p_1 - q_1).
\end{cases}$$  \(25\)

### 3.1 Polarization modulation profiles

We first look at the polarization modulation profiles of the ferroelectric/dielectric superlattice under the absence of an external electric field $E = 0$ (Chew et al., 2009). The polarization profiles of $p$ and $q$ for the ferroelectric and dielectric layers, respectively, can be obtained using the Euler-Lagrange equation. For the dielectric layer, the Euler-Lagrange equation is

$$\kappa_2 \frac{d^2 q}{dx^2} = \alpha_2 q ,$$  \(26\)

and $q(x)$ can be obtained as

$$q(x) = q_c \cosh K_2 \left( x - \frac{L}{2} \right) ,$$  \(27\)

and at the interface, we have

$$q_i = q_c \cosh \frac{K_2 L_2}{2} ,$$  \(28\)

where $q_c$ is the $q$ value at $dq / dx = 0$.

By integrating once, the Euler-Lagrange equation of the ferroelectric layer is

$$\frac{\kappa_1}{2} \left( \frac{dp}{dx} \right)^2 = \frac{\alpha_1}{2} (p^2 - p_c^2) + \frac{\beta_1}{4} (p^4 - p_c^4) ,$$  \(29\)
where \( p_c \) is the \( p \) value at \( dp/dx = 0 \). In this case, \( p_c \) is the maximum value of \( p \) at \( x = 0 \). Using \( p(x) = p_s \sin \theta(x) \) and \( p_b^2 = -\alpha_1 / \beta_1 \), eq. (29) becomes

\[
\sqrt{-\alpha_1} \int \frac{dx}{\sqrt{\kappa_1(1 + k^2) - L_1/2}} = \theta \int \frac{d\theta}{\sqrt{1 - k^2 \sin^2 \theta}},
\]

(30)

where \( F(\theta, k) \) and \( F(\theta, k) \) are the elliptic integral of the first kind with the elliptic modulus \( k \) given by

\[
k^2 = \frac{p_c^2}{2p_b^2 - p_c^2}.
\]

(31)

Fig. 4. Spatial dependence of polarization for a superlattice with \( L_1 = 5 \) and \( L_2 = 3 \) for various \( \lambda^{-1} \). The parameters adopted for the calculation are: \( \alpha_1 = -1, \ \alpha_2 = 0.1, \ \beta_1 = 1, \ \beta_2 = 1, \ \kappa_1 = 4 \) and \( \kappa_2 = 9 \). In the curves, the values for \( \lambda^{-1} \) are: 100 (dot), 16 (dash-dot-dot), 8 (dash-dot), 2 (dash), and 0 (solid). Dotted circles represent the interface polarizations (Chew et al., 2009).

Let us discuss the polarization modulation profiles in a ferroelectric/dielectric superlattice using the explicit expressions. The characteristic lengths of polarization modulations in the ferroelectric layer near the transition point and the dielectric layer are given by \( K_1^{-1} = \sqrt{-\kappa_1 / \alpha_1} \) and \( K_2^{-1} = \sqrt{\kappa_2 / \alpha_2} \), respectively. Figure 4 illustrates an example of \( \lambda^{-1} \) dependence of polarization modulation profiles. It is seen that the modulation of the polarization is obvious in the ferroelectric layer, but not in the dielectric layer. This is because \( L_1 / 2 > \sqrt{-\kappa_1 / \alpha_1} = 2 \) and \( L_2 / 2 < \sqrt{\kappa_2 / \alpha_2} = 0.95 \). For a loosely coupled superlattice of \( \lambda^{-1} = 100 \) (dot lines), only a weak polarization is induced in the dielectric layer. As the strength of the interface coupling \( \lambda \) increases, the polarization near the interface of the ferroelectric layer is slightly suppressed, whereas the induced-polarization of the soft dielectric layer increases.
3.2 Phase transitions

Using the explicit expressions (as obtained in Sect. 3.1), the average energy density of the superlattice $F$ (eq. (22)) can be written in terms of $p_c$ and $q_c$ as (Chew et al., 2009)

$$F = \frac{2}{L} \left[ \frac{-\alpha_1 \kappa_1}{\sqrt{1 + k^2}} p_c^2 + \left( \frac{\alpha_1}{2} p_c^2 + \beta_1 p_c^4 \right) L_1 \frac{1}{2} + \lambda \frac{p_c^2}{2} \sin^2 \theta_l - C p_c q_c + \frac{D}{2} q_c^2 \right],$$  

(32)

where

$$C = \lambda \cosh \left( \frac{K_2 L_2}{2} \right) \sin \theta_l,$$

$$D = \frac{\sqrt{\alpha_2 \kappa_1}}{2} \sinh \left( \frac{K_2 L_2}{2} \right) + \lambda \cosh \left( \frac{K_2 L_2}{2} \right),$$

$$J = \int_{\pi/2}^{\theta_l} \cos^2 \theta \sqrt{1 - k^2 \sin^2 \theta} \, d\theta,$$  

(33)

with $\theta_l = \sin^{-1} \left( \frac{p_l}{p_c} \right)$. By utilizing $k^2 = p_c^2 \left( 2p_b^2 \right)$ and $K_1$ (see eq. (12)) near the transition point, $F$ becomes

$$F = \frac{2}{L} \left[ \frac{A}{2} p_c^2 + O \left( p_c^4 \right) - C p_c q_c + \frac{D}{2} q_c^2 \right],$$  

(34)

where

$$A = -\frac{\sqrt{-\alpha_1 \kappa_1}}{2} \sin K_1 L_1 + \lambda \cos^2 \frac{K_1 L_1}{2},$$  

(35)

and $O(p_c^4)$ indicates the higher order terms of $p_c^4$.

From the equilibrium condition for $q_c$, $dF/dq_c = 0$, the condition of the transition point can be obtained as $A - C^2/D = 0$, i.e.,

$$-\frac{\sqrt{-\alpha_1 \kappa_1}}{2} \sin K_1 L_1 + R \cos^2 \frac{K_1 L_1}{2} = 0,$$  

(36)

where

$$R = \frac{\lambda r}{\lambda + r}, \quad r = \sqrt{\alpha_2 \kappa_2 \tanh \frac{K_2 L_2}{2}}.$$  

(37)

In Fig. 5, we show the dependence of $p_c$ and $q_c$ on $\lambda^{-1}$ for different dielectric stiffness $\alpha_2$.

For a superlattice with a soft dielectric layer $\alpha_2 = 0.1$ and 1, $p_c$ remains almost the same as the bulk polarization $p_{c_b} \approx p_b$ for all $\lambda^{-1}$. For the case with $\alpha_2 = 5$, $p_c$ is suppressed near the strong coupling regime $\lambda^{-1} \approx 0$. If the dielectric layer is very rigid ($\alpha_2 = 10$ and 50), we found that $p_c$ is strongly suppressed with increasing interface coupling and $q_c$ remains very weak. It is seen that the polarizations of the superlattices with rigid dielectric layers are completely disappeared at $\lambda^{-1} = 0.0514$ and 0.1189, respectively. These transition points can be obtained using eq. (36).
As the temperature increases, the ferroelectric layer can be in the ferroelectric state or in the paraelectric state. Phase transition may or may not take place, depending on the model parameters. Let us examine the stability of superlattice in the paraelectric state by taking into account the polarization profile to appear in the ferroelectric state. Instead of the exact solutions obtained from the Euler-Lagrange equations, which are in term of the Jacobi Elliptic Functions, we use (Ishibashi & Iwata, 2007)

\[ p = p_c \cos K_1 x, \]  

thus \( p_i \) becomes

\[ p_i = p_c \cos \frac{K_1 L_1}{2}. \]  

The Euler-Lagrange equation for \( q \) is given by eq. (26), which gives \( q(x) \) as expressed in eq. (27). Substitution of eqs. (27) and (38) into eq. (22), \( F \) becomes

\[ F = \frac{2}{L} \left[ \frac{a_1}{2} p_c^2 + \frac{b_1}{4} p_c^4 + \frac{a_2}{2} q_c^2 - c p_c q_c \right], \]  

where
Similarly, from the equilibrium condition for \( q_c \), \( \frac{dF}{dq_c} = 0 \), we find eq. (40) can be reduced to a more simple form as
\[
F = \frac{2}{L} \left[ \frac{a_1^*}{2} p_c^2 + \frac{b_1}{4} p_c^4 \right],
\]
where
\[
a_1^* = \frac{L_1}{4} \left[ \alpha_1 + \kappa_1 K_1^2 + \frac{\alpha_1 - \kappa_1 K_1^2}{K_1 L_1} \sin K_1 L_1 \right] + R \cos^2 \frac{K_1 L_1}{2},
\]
where \( R(\lambda, r) \) is given by eq. (37). \( r \) is a function of \( \alpha_2, \kappa_2 \) and \( L_2 \). The transitions of the superlattice from a paraelectric phase to a ferroelectric state occurs when \( a_1^* = 0 \). Note here that \( a_1^* \) consists of the physical parameters from both the ferroelectric and dielectric layers. It is seen that the influence of the dielectric layer via \( \lambda \) becomes stronger with increasing \( \alpha_2, \kappa_2 \) and \( L_2 \). However, the influence is limited at most to \( r_{\text{max}} = \sqrt{\alpha_2 \kappa_2} \). Let us look at \( a_1^* \) in more detail. By taking \( \frac{\partial a_1^*}{\partial K_1} \bigg|_{K_1=k} = 0 \), we obtain the wave number \( k \). It is qualitatively

Fig. 6. The dependence of the wave number \( k \) for various \( R/L_1 \) when \( \kappa_1 = 1 \) and \( L_1 = 1/2 \). The curves show the cases 1) \( R/L_1 = 0 \), 2) \( R/L_1 = 2 \), 3) \( R/L_1 = 20 \), 4) \( R/L_1 = 200 \) and 5) \( R/L_1 = \infty \). Dotted lines denote the transition point of each case (Ishibashi & Iwata, 2007).
obvious that $k$ is small, implying a flat polarization profile, when the contribution from the
dielectric layer $R$, is small, while $kL_2$ approaches $\pi$, implying a very weak interface
polarization in the ferroelectric layer, when $R$ is extremely large. The dependence of the
wave number $k$ on $\alpha_1$ for various $R/L_1$ is illustrated in Fig. 6.

3.3 Dielectric susceptibilities
In this section, we will discuss the dielectric susceptibility of the superlattice in the
paraelectric phase (Chew et al., 2008). Since $p(x) = q(x) = 0$ in the paraelectric phase (if $E = 0$),
the modulated polarizations, $p(x)$ and $q(x)$, are the polarizations induced by the electric field $E$. The contribution from the higher-order term $\beta_1 p^4 / 4$ is neglected because we consider only the paraelectric phase. By solving the Euler-Lagrange equations, we found

$$
\begin{align*}
\alpha_1 p - \kappa_1 \frac{d^2 p}{dx^2} &= E, \\
\alpha_2 q - \kappa_2 \frac{d^2 q}{dx^2} &= E,
\end{align*}
$$

(44)

with the condition that $F$ (eq. (22)) including the interface energy (eq. (3)) takes the
minimum value. Note that in the present system, the ferroelectric transition point $\alpha_c$ is
negative. Thus, one must consider both cases $\alpha_1 \geq 0$ and $\alpha_1 < 0$ in the study of the dielectric
susceptibility even in the paraelectric phase. In the present system, the dielectric
susceptibility $\chi$ is defined as

$$
\chi = \frac{2}{LE} \left[ \int_0^{L_1/2} p \, dx + \int_{L_1/2}^{L/2} q \, dx \right].
$$

(45)

3.3.1 Case $\alpha_1 \geq 0$
For the case of $\alpha_1 \geq 0$, the exact solutions are

$$
\begin{align*}
p &= p_c E \cosh K_1 x + \frac{E}{\alpha_1}, \\
q &= q_c E \cosh K_2 \left( x - \frac{L}{2} \right) + \frac{E}{\alpha_2},
\end{align*}
$$

(46)

and

$$
\begin{align*}
p_1 &= p_c E \cosh \frac{K_1 L_1}{2} + \frac{E}{\alpha_1}, \\
q_1 &= q_c E \cosh \frac{K_2 L_2}{2} + \frac{E}{\alpha_2}.
\end{align*}
$$

(47)

In this case, $K_1 = \sqrt{\alpha_1 / \kappa_1}$ and $K_2$ is given by eq. (14). By utilizing eqs. (46) and (47), we can express $F$ in terms of $p_c$ and $q_c$ as
\[ F = \frac{2}{L} \left( \frac{a_1}{2} p_c^2 + \frac{a_2}{2} q_c^2 - c p_c q_c - d_1 p_c - d_2 q_c \right) E^2, \]  

(48)

where

\[
\begin{align*}
    a_1 &= \frac{\alpha_1}{2K_1} \sinh K_1 L_1 + \lambda \cosh^2 \frac{K_1 L_1}{2}, \\
    a_2 &= \frac{\alpha_2}{2K_2} \sinh K_2 L_2 + \lambda \cosh^2 \frac{K_2 L_2}{2}, \\
    c &= \lambda \cosh \frac{K_1 L_1}{2} \cosh \frac{K_2 L_2}{2}, \\
    d_1 &= -\lambda \cosh \frac{K_1 L_1}{2} \left( \frac{1}{\alpha_1} - \frac{1}{\alpha_2} \right), \\
    d_2 &= \lambda \cosh \frac{K_2 L_2}{2} \left( \frac{1}{\alpha_1} - \frac{1}{\alpha_2} \right). 
\end{align*}
\]

(49)

Using the equilibrium conditions \( \partial F / \partial p_c = \partial F / \partial q_c = 0 \), we find

\[ p_c = -\frac{\lambda}{a_2 A} \left( \frac{a_2}{2K_2} \cosh \frac{K_1 L_1}{2} \sinh \frac{K_2 L_2}{2} \right) \left( \frac{1}{\alpha_1} - \frac{1}{\alpha_2} \right), \]

(50)

and

\[ q_c = \frac{\lambda}{a_2 A} \left( \frac{a_1}{2K_1} \cosh \frac{K_2 L_2}{2} \sinh \frac{K_1 L_1}{2} \right) \left( \frac{1}{\alpha_1} - \frac{1}{\alpha_2} \right), \]

(51)

where

\[ A = a_1 - \frac{c^2}{a_2}. \]

(52)

Based on eq. (45), the dielectric susceptibility for the present case is

\[ \chi = \frac{2p_c}{K_1 L} \sinh \frac{K_1 L_1}{2} + \frac{L_1}{K_1 L} p_c + \frac{2q_c}{K_2 L} \sinh \frac{K_2 L_2}{2} + \frac{L_2}{K_2 L} q_c. \]

(53)

3.3.2 Case \( \alpha_1 < 0 \)

In this case, the exact solutions of eq. (44) are

\[
\begin{align*}
    p &= p_c E \cos K_1 x + \frac{E}{\alpha_1}, \\
    q &= q_c E \cosh K_2 \left( x - \frac{L}{2} \right) + \frac{E}{\alpha_2}, 
\end{align*}
\]

(54)
where $K_1$ and $K_2$ are given by eq. (12) and (14), respectively. Thus, we have

$$
\begin{align*}
\begin{cases}
  p_i = p_c E \cos \frac{K_1 L_1}{2} + \frac{E}{\alpha_1}, \\
  q_i = q_c E \cosh \frac{K_2 L_2}{2} + \frac{E}{\alpha_2}.
\end{cases}
\end{align*}
$$

(55)

Similarly, we find

$$
F = \frac{2}{L} \left( \frac{a_1}{2} p_c^2 + \frac{a_2}{2} q_c^2 - c p_c q_c - d_1 p_c - d_2 q_c \right) E^2,
$$

(56)

where

$$
\begin{align*}
  a_1 &= \frac{\alpha_1}{2K_1} \sin K_1 L_1 + \lambda \cos^2 \frac{K_1 L_1}{2}, \\
  a_2 &= \frac{\alpha_2}{2K_2} \sinh K_2 L_2 + \lambda \cosh^2 \frac{K_2 L_2}{2}, \\
  c &= \lambda \cos \frac{K_1 L_1}{2} \cosh \frac{K_2 L_2}{2}, \\
  d_1 &= -\lambda \cos \frac{K_1 L_1}{2} \left( \frac{1}{\alpha_1} - \frac{1}{\alpha_2} \right), \\
  d_2 &= \lambda \cosh \frac{K_2 L_2}{2} \left( \frac{1}{\alpha_1} - \frac{1}{\alpha_2} \right),
\end{align*}
$$

(57)

and the values of $p_c$ and $q_c$ become

$$
\begin{align*}
  p_c &= -\frac{\lambda}{a_2 A} \left( \frac{\alpha_2}{2K_2} \cos \frac{K_1 L_1}{2} \sinh K_2 L_2 \right) \left( \frac{1}{\alpha_1} - \frac{1}{\alpha_2} \right),
\end{align*}
$$

(58)

and

$$
\begin{align*}
  q_c &= \frac{\lambda}{a_2 A} \left( \frac{\alpha_1}{2K_1} \cosh \frac{K_2 L_2}{2} \sin K_1 L_1 \right) \left( \frac{1}{\alpha_1} - \frac{1}{\alpha_2} \right),
\end{align*}
$$

(59)

with

$$
\lambda = a_1 - \frac{c^2}{a_2}.
$$

(60)

Using eqs. (45), the dielectric susceptibility $\chi$ for the present case of $\alpha_1 < 0$ is

$$
\chi = \frac{2p_c}{K_1 L} \sin \frac{K_1 L_1}{2} + \frac{L_1}{\lambda \alpha_1} + \frac{2q_c}{K_2 L} \sinh \frac{K_2 L_2}{2} + \frac{L_2}{\lambda \alpha_2},
$$

(61)
where the phase transition point is given by \( A = a_1 - c^2 / a_2 = 0 \). Using \( A = a_1 - c^2 / a_2 = 0 \), the condition of the transition point is

\[
\frac{\alpha_1}{2K_1} \sin K_1 L_1 + \frac{\lambda - \frac{\alpha_2}{2K_2} \sin K_2 L_2}{2K_2} \cos^2 \frac{K_2 L_2}{2} = 0. \quad (62)
\]

It is interesting to note here that the transition temperature \( \alpha_1 \) can be determined using eq. (62), which is exactly the same as eq. (43) (Ishibashi & Iwata, 2007).

Fig. 7. Reciprocal susceptibility as a function of \( \alpha_1 \). The parameter values are adopted as \( L = 1, L_1 = L_2 = 1 / 2, \kappa_1 = \kappa_2 = 1, \alpha_2 = 1 \), for cases of: (1) \( \lambda = 0 \), (2) \( \lambda = 0.3 \), (3) \( \lambda = 3 \) (Chew et al., 2008).

Fig. 8. Spatial dependence of polarization for a superlattice with \( L_1 = L_2 = 3 \). The parameters adopted for the calculation are: \( \kappa_1 = \kappa_2 = 1 \), \( \alpha_2 = 1 \), \( \lambda = 3 \), for cases of (1) \( \alpha_1 = -0.1 \), (2) \( \alpha_1 = 0 \), (3) \( \alpha_1 = 0.2 \) (Chew et al., 2008).

In Fig. 7, we show the reciprocal susceptibility \( 1 / \chi \) in various parameter values. It is found that the average susceptibility diverges at the transition temperature obtained from eq. (62).
The result indicates that the second-order phase transition is possible in our model of the superlattice structure. It is seen that the susceptibility is continuous at $\alpha_1 = 0$, though the susceptibility is divided into two different functions at $\alpha_1 = 0$. Taking the limit of $\alpha_1 = \pm 0$ from both the positive and negative sides, the explicit expression for the susceptibility at $\alpha_1 = 0$ is

$$
\chi = \frac{1}{2L} \left[ \frac{2L_1 + L_2}{\alpha_2} + \frac{L_1^2}{2\lambda} + \frac{L_1^3}{12\kappa_1} + \frac{L_2^2K_2}{\alpha_2} \cosh \frac{2K_2L_2}{\alpha_2} + \frac{2K_2L_2}{\sinh K_2L_2} \right],
$$

(63)

implying that the susceptibility is always continuous at $\alpha_1 = 0$. It is worthwhile to look at the field-induced polarization profile at $\alpha_1 = 0$ because $K_1$ becomes zero at $\alpha_1 = 0$. By taking the limit of $\alpha_1 = \pm 0$ from both the positive and negative sides for the polarization $p$, the expressions for the polarization profiles in $p(x)$ and $q(x)$ can be explicitly expressed as

$$
p(x) = \frac{E}{8\kappa_1} \left( L_1^2 - 4x^2 \right) + \frac{EL_1}{2\lambda} + \frac{EK_2L_1}{\alpha_2} \cosh \frac{2K_2L_2}{\alpha_2} + \frac{E}{\alpha_2},
$$

(64)

and

$$
q(x) = \frac{EK_2L_1 \cosh \frac{K_2L_2}{\alpha_2}}{\sinh K_2L_2} \left[ K_2 \left( x - \frac{L}{2} \right) \right] + \frac{E}{\alpha_2}
$$

(65)

Equation (64) depicts the polarization profile $p(x)$ that exhibits a parabolic modulation at $\alpha_1 = 0$, as shown in Fig. 8. The polarization profile obtained near the transition point may coincide with the polarization modulation pattern of the ferroelectric soft mode in the paraelectric phase.

3.4 Application of model to epitaxial PbTiO$_3$/SrTiO$_3$ superlattices

Let us extend the model to study the ferroelectric polarization of epitaxial PbTiO$_3$/SrTiO$_3$ (PT/ST) superlattices grown on ST substrate and under a short-circuit condition, as schematically shown in Fig. 9. Some key points from the previous sections are repeated here for clarity of discussion.

In this study, we need to include the effects of interface, depolarization field and substrate-induced strain in the model. By assuming that all spatial variation of polarization takes place along the $z$-direction, the Landau-Ginzburg free energy per unit area for one period of the PT/ST superlattice can be expressed as (Chew et al., unpublished)

$$
F = F_{PT} + F_{ST} + F_1,
$$

(66)

where the free energy per unit area for the PT layer with thickness $L_{PT}$ is

$$
F_{PT} = \int_{-L_{PT}}^{0} \left[ \frac{\alpha_{PT}^*}{2} p^2 + \frac{\beta_{PT}^*}{4} p^4 + \frac{\gamma_{PT}^*}{6} p^6 + \frac{\kappa_{PT}}{2} \left( \frac{dp}{dz} \right)^2 + \frac{u_{m,PT}^2}{s_{11,PT} + s_{12,PT}} \right] dz
$$

(67)
Fig. 9. Schematic illustration of a periodic superlattice composed of a ferroelectric and a paraelectric layers. The thicknesses of PbTiO$_3$ (PT) and SrTiO$_3$ (ST) layers are $L_{PT}$ and $L_{ST}$, respectively. $L$ denotes the periodic thickness of the PT/ST superlattice.

and the free energy per unit area for the ST layer with thickness $L_{ST}$ is

$$F_{ST} = \int_0^{L_{ST}} \left[ \frac{\alpha_{ST}^*}{2} q^2 + \frac{\beta_{ST}^*}{4} q^4 + \frac{\gamma_{ST}}{6} q^6 + \frac{\kappa_{ST}}{2} \left( \frac{dq}{dz} \right)^2 + \frac{u_{m,ST}^2}{s_{11,ST} + s_{12,ST}} \right] dz \tag{68}$$

where $p$ and $q$ corresponds to the polarization of PT and ST layers, respectively. For the superlattices with the polarizations perpendicular to the layer’s surfaces/interfaces, the inhomogeneity of polarization means that the depolarization field effect is essential. In eqs. (67) and (68), $\alpha_j^*$ and $\beta_j^*$ are expressed as

$$\begin{align*}
\alpha_j^* &= \alpha_j - \frac{4Q_{12,j}}{s_{11,j} + s_{12,j}} u_{m,j}, \\
\beta_j^* &= \beta_j + \frac{4Q_{12,j}^2}{s_{11,j} + s_{12,j}}
\end{align*}$$

where $\alpha_j$, $\beta_j$ and $\gamma_j$ are the Landau coefficients of layer $j$ ($j :$ PT or ST), as usual. $s_{11,j}$ and $s_{12,j}$ are the elastic compliance coefficients, whereas $Q_{12,j}$ is the electrostrictive constant. $u_{m,j} = (a_j - a_s) / a_s$ denotes the in-plane misfit strain induced by the substrate due to the lattice mismatch. $a_j$ is the unconstrained equivalent cubic cell lattice constants of layer $j$ and $a_s$ is the lattice parameter of the substrate. $\kappa_j^*$ is the gradient coefficient, determining the energy cost due to the inhomogeneity of polarization.
With the assumption that the ferroelectric layers are insulators with no space charges, the depolarization field \( e_{d,j} \) in the PT and ST layers can be expressed by

\[
\begin{align*}
    e_{d,PT}(z) &= -\frac{1}{\varepsilon_0}(p(z) - P), \\
    e_{d,ST}(z) &= -\frac{1}{\varepsilon_0}(q(z) - P),
\end{align*}
\]

respectively. In eq. (70), \( \varepsilon_0 \) denotes the dielectric permittivity in vacuum. The second term describes the mean polarization of one-period superlattice

\[
P = \frac{1}{L} \left( \int_{-L_{PT}}^{0} p(z) \, dz + \int_{0}^{L_{ST}} q(z) \, dz \right),
\]

with the periodic thickness \( L = L_{PT} + L_{ST} \). It is important to note here that \( e_{d,j} \) acts as the depolarization field, if its direction is opposite to the direction of ferroelectric polarization. If \( e_{d,j} \) inclines in the same direction of polarization, it cannot be regarded as the depolarization field; thus, we denote \( e_{d,j} \) as “the internal electric field”. Hence, the average internal electric field of one-period superlattice is defined as

\[
E_d = \frac{1}{L} \left[ \int_{-L_{PT}}^{0} e_{d,PT}(z) \, dz + \int_{0}^{L_{ST}} e_{d,ST}(z) \, dz \right].
\]

The intrinsic coupling energy between the polarizations at the interfaces \( z=0 \) of the two layers is described as

\[
F_i = \frac{\lambda}{2} (p_i - q_i)^2,
\]

where \( p_i \) and \( q_i \) are the interface polarizations at \( z=0 \) for the PT and ST layers, respectively. In eq. (73), the parameter \( \lambda \) describes the strength of intrinsic interface coupling and it can be conveniently related to the dielectric permittivity in vacuum \( \varepsilon_0 \) as

\[
\lambda = \frac{\lambda_0}{\varepsilon_0},
\]

where \( \lambda_0 \) denote the temperature-independent interface coupling constant. In this case, the existence of the interface coupling \( \lambda \neq 0 \) leads to the inhomogeneity of polarization near the interfaces, besides the effect of the depolarization field.

In the calculations, it is assumed that 1 unit cell (u.c.) \( \approx 0.4 \text{ nm} \) and the thickness of ST layer is maintained at \( L_{ST} \approx 3 \text{ u.c.} \). The lattice constants in the paraelectric state are \( a_A = 3.969 \text{ Å} \) and \( a_B = 3.905 \text{ Å} \) for PT and ST layers, respectively. Based on the lattice constants, the lattice strains are obtained as \( u_{m,PT} = -0.0164 \) and \( u_{m,ST} = 0 \).

In Fig. 10, we show the average polarization \( P \) and internal electric fields \( E_d \) of PT/ST superlattices as a function of thickness ratio \( L_{PT}/L_{ST} \) for different strength of interface coupling \( \lambda_0 \). It is seen that \( P \) and \( E_d \) decrease with increasing \( \lambda_0 \). As \( \lambda_0 \) increases, the
critical thickness ratio (at which $P$ vanishes) shifts to a higher value. It is seen that there is a good agreement between the calculated and measured polarizations. The calculated polarizations using $\lambda_0 = 10$ (black line) agree reasonably well with most of the experimental measurements for $L_{PT}/L_{ST} > 0.4$, implying that the strength of interface coupling at this regime is strong. At the $L_{PT}/L_{ST} \leq 0.4$ region, the predicted polarizations with $\lambda_0 = 0.2$ (red line) and 0.05 (blue line) agree well with some of the experimental measurements. The $E_d$ versus $L_{PT}/L_{ST}$ curves show a trend similar to $P$ versus $L_{PT}/L_{ST}$, e.g. $E_d$ disappears at a critical thickness ratio. For each $\lambda_0$, the critical thickness ratio of $E_d$ coincides with that of $P$. It is remarkable to see that for $E_d > 0$, internal electric field is parallel to the direction of the ferroelectric polarization in PT layer, which enhances the polarization of the superlattice.

![Fig. 10. Polarization and internal electric field as a function of thickness ratio $L_{PT}/L_{ST}$ of PT/ST superlattices at $T = 300K$. The values of $\lambda_0$ are: 10 (▬), 0.2 (▬) and 0.05 (▬). Solid dots (●) represent experimental results from Dawber et al (Dawber et al., 2007). The insets in each figure show the corresponding curves in smaller scale (Chew et al., unpublished).](image)

4. Conclusion

We have proposed a model to study the intrinsic interface coupling in ferroelectric heterostructure and superlattices. The layered structure is described using the Landau-Ginzburg theory by incorporating the effect of coupling at the interface between the two constituents. Explicit analytical expressions describing the polarization at the interface
between bulk ferroelectrics and bulk dielectrics were derived and discussed. Here, we mainly discussed only cases where the transition of the ferroelectric constituent is of second order (Chew et al., 2003), though cases of heterostructure at the interfaces involving first-order phase transition were also reported (Tsang et al., 2004).

We further extend the model to investigate the ferroelectricity of superlattice by incorporating the thickness effect. Using the explicit expressions derived from the model, the polarization modulation profiles, phase transitions and dielectric susceptibilities of a superlattice are presented and discussed in detail (Ishibashi & Iwata, 2007; Chew et al., 2008; Chew et al., 2009). The effort to obtain the explicit analytical solutions using the continuum model of Landau-Ginzburg theory is worthwhile. This is because those expressions allow us to gain general insight on how the intrinsic polarization coupling at the interface influences the physical properties of those hybrid structures. Note that the effect of an applied electric field on the polarization behaviors of heterostructure at the interfaces (Chew et al., 2005; Chew et al., 2006) and superlattices (Chew et al., 2011; Chew et al., unpublished) is also very important. However, those studies were not discussed. We have also constructed a one-dimensional model on the basis of the Landau-Ginzburg theory to investigate the polarization and dielectric behaviors (Chew et al., 2006; Chew et al., 2007), as well as the switching characteristics (Chew et al., unpublished).

At the end of the discussion, we show how the present model can be applied to study the ferroelectric polarization of epitaxial PT/ST superlattices with the polarizations perpendicular to the surfaces/interfaces of the constituent layers (Chew et al., unpublished). The effects of interface, depolarization field and substrate-induced strain are required to include in the model. Our calculated polarizations (Chew et al., unpublished) agree reasonably well with recent experimental measurements (Dawber et al., 2007). From our study, it suggests that the recent experimental observation on the unusual recovery of ferroelectricity at thickness ratio of $L_{PT}/L_{ST} < 0.5$ (Dawber et al., 2005) may be related to a weakening of ferroelectric coupling at the interface. It is certainly interesting to look at the dielectric susceptibilities and polarization reversals of the superlattices, which will be reported elsewhere.

Ferroelectric materials have been and still are widely used in many applications, that have moved from sonar towards breakthrough technologies such as memories or optical devices. This book is a part of a four volume collection (covering material aspects, physical effects, characterization and modeling, and applications) and focuses on the characterization of ferroelectric materials, including structural, electrical and multiphysic aspects, as well as innovative techniques for modeling and predicting the performance of these devices using phenomenological approaches and nonlinear methods. Hence, the aim of this book is to provide an up-to-date review of recent scientific findings and recent advances in the field of ferroelectric system characterization and modeling, allowing a deep understanding of ferroelectricity.
