Abstract

We consider the maximum mean discrepancy (MMD) GAN problem and propose a parametric kernelized gradient flow that mimics the min-max game in gradient regularized MMD GAN. We show that this flow provides a descent direction minimizing the MMD on a statistical manifold of probability distributions. We then derive an explicit condition which ensures that gradient descent on the parameter space of the generator in gradient regularized MMD GAN is globally convergent to the target distribution. Under this condition, we give non asymptotic convergence results of gradient descent in MMD GAN. Another contribution of this paper is the introduction of a dynamic formulation of a regularization of MMD and demonstrating that the parametric kernelized descent for MMD is the gradient flow of this functional with respect to the new Riemannian structure. Our obtained theoretical result allows ones to treat gradient flows for quite general functionals and thus has potential applications to other types of variational inferences on a statistical manifold beyond GANs. Finally, numerical experiments suggest that our parametric kernelized gradient flow stabilizes GAN training and guarantees convergence.

1 Introduction

Generative Adversarial Networks (GANs) were introduced in [16] and have attracted growing attention in the machine learning community. Implicit Generative models such as GANs can be seen as learning a distribution via optimizing a functional defined on a statistical manifold. The statistical manifold refers to the parametrization of the Generator. There are a plethora of works on functionals that are optimized in GANs for example the Jensen-Shanon divergence in the original work [16]; general $\phi$ divergences in [34]; the neural net distance in [26]; integral probability metrics such as the Wasserstein order $1$ distance considered in [4]; the maximum mean discrepancy [17] considered in [15, 20, 21, 29, 38]. Despite their striking empirical success, the rigorous understanding of the convergence in distributional sense of gradient descent in GANs remains less understood. Much of the theoretical analysis has been dedicated to the stability of the min-max game via the introduction of gradient regularizers [2, 18, 27, 28, 30, 33, 36]. Min-max convergence rates for a large class of GANs was studied in [22, 40], however these bounds are not specific to gradient descent in GANs. In this work we aim at understanding the distributional convergence properties of gradient descent in the context of MMD GANs. The work closest to ours is [9] that establishes global convergence of the generator using the Wasserstein $1$ distance. Nevertheless, gradient descent is not explicitly considered in [9].

We summarize our main contributions in this work as follows:

- We introduce in Section 3 a new gradient regularizer for the MMD. The new regularizer has the form of a parametric energy, where the gradient is taken with respect to the generator parameters, instead of the input space as usually considered in previous works. We call the new proposed discrepancy $\text{MMD}_{a,\beta}$. 

arXiv:2011.02402v1 [cs.LG] 4 Nov 2020
• We consider the MMD GAN problem in Section 4 and propose a new descent direction in terms of the witness function of the parametric regularized MMD. We give in this section detailed descriptions and properties of the corresponding continuous flow.

• We analyze in Section 5 the non-asymptotic distributional convergence properties of gradient descent in MMD GAN when using the MMD witness functions to drive the generator updates.

• We derive in Section 6 a dynamic formulation of the MMD on the statistical manifold of probability distributions and use it to propose a novel regularization of the MMD, which we call $d_{a,\beta}$. We show that $d_{a,\beta}$ admits a Riemannian metric tensor and investigate gradient flows for general functionals w.r.t. this structure. Intriguingly, we show that gradient descent in MMD GANs driven by the witness function of MMD coincides with the gradient flow of the MMD w.r.t. this new geometric structure.

• Finally, we discuss related works in Section 7, and validate experimentally our theoretical findings in Section 8.

2 Preliminaries

Let $\Omega$ be an open region in $\mathbb{R}^d$ and let $\mathcal{H}$ be a reproducing kernel Hilbert space (RKHS) generated by a kernel $k(x,y)$ on $\Omega \times \Omega$. Let $Z \subset \mathbb{R}^m$ be an open region on a lower dimensional space endowed with a probability distribution $\nu$ on $Z$. Let $\Theta$ be a parameter space in $\mathbb{R}^p$, and $(\theta,z) \rightarrow G_\theta(z) = \left(G^1_\theta(z), \ldots, G^d_\theta(z)\right) \in \Omega$ be a generator function defined on $\Theta$. We assume that $k$ is bounded, $G_\theta$ is differentiable in $\theta$, and

$$
\|k(x,\cdot) - k(y,\cdot)\|_{\mathcal{H}} \leq L \|x - y\| \quad \text{and} \quad \|G_\theta(z) - G_{\theta'}(z)\| \leq D(z) \|\theta - \theta'\|
$$

for some constant $L > 0$ and function $D : Z \rightarrow [0,\infty)$ with $\mathbb{E}_\nu[D(z)^2] < \infty$. In (1) and throughout the paper, $\langle \cdot, \cdot \rangle$ and $\| \cdot \|$ denote the standard Euclidean inner product and norm, while $\langle \cdot, \cdot \rangle_{\mathcal{H}}$ and $\| \cdot \|_{\mathcal{H}}$ denote the inner product and norm on $\mathcal{H}$. For a probability distribution $\rho$ on $\Omega$, let $\mu_\rho(x) := \int k(x,y)\rho(dy)$ denote its kernel mean embedding. As $k$ is bounded, we have $\mu_\rho \in \mathcal{H}$ and $\int f(x)\rho(dx) = \langle f, \mu_\rho \rangle_{\mathcal{H}}$ for every $f \in \mathcal{H}$ (see [32]). Note that $\mu_{\rho_1} - \mu_{\rho_2} = \mu_{\rho_1 - \rho_2}$ by linearity.

We consider the following statistical manifold of probability distributions:

$$
\mathcal{P}_\Theta := \{q_\theta = (G_\theta)_\#\nu, \ \theta \in \Theta\}.
$$

The main objective functions considered in this paper are parametric energy regularizations of $\text{MMD}(p,q_\theta) := \|\mu_p - \mu_{q_\theta}\|_{\mathcal{H}}$ and the introduction of the following operators plays an important role in understanding these objective functions and associated gradient flows.

**Definition 1 (Matrix Mass).** Let $J_\theta G_\theta(z) = \left(\frac{\partial G^i_\theta(z)}{\partial \theta^j}\right)_{ij} \in \mathbb{R}^{p \times d}$ denote the Jacobian of $G_\theta$ with respect to $\theta$. Then for $\theta \in \Theta$, we define a matrix valued kernel $\Gamma_\theta$ on $Z \times Z$ as follows, for $(z,z') \in Z \times Z$:

$$
\Gamma_\theta(z,z') := J_\theta G_\theta(z) \top^T J_\theta G_\theta(z') \in \mathbb{R}^{d \times d}.
$$

**Definition 2 (Parametric Grammian - Mass Corrected Grammian of Derivatives).** For $\theta \in \Theta$, let $L_\theta : \mathcal{H} \rightarrow \mathbb{R}^p$ be the operator given by

$$
L_\theta(f) := \int J_\theta G_\theta(z) \nabla f(G_\theta(z))\nu(dz)
$$
and $L^\top_\theta : \mathbb{R}^p \to \mathcal{H}$ be the operator given by

$$L^\top_\theta (\nu) := \int (\nabla_\theta [k(G_\theta(z)),\cdot], \nu) \, v(dz) = \int (\nabla x k(G_\theta(z)), I_\theta G_\theta(z)^\top \nu) \, v(dz).$$

Then the parametric Grammian $D_\theta : \mathcal{H} \to \mathcal{H}$ is defined by $D_\theta := L^\top_\theta L_\theta$.

The main properties of these operators are summarized as follows. Proofs are given in the Appendix.

**Proposition 3.** For each $\theta \in \Theta$, we have

i) $L^\top_\theta$ is the adjoint operator of $L_\theta$, i.e., $\langle L_\theta f, \nu \rangle = \langle f, L^\top_\theta \nu \rangle_{\mathcal{H}}$ for $f \in \mathcal{H}$ and $\nu \in \mathbb{R}^p$.

ii) $D_\theta$ is symmetric, i.e., $\langle D_\theta f, g \rangle_{\mathcal{H}} = \langle f, D_\theta g \rangle_{\mathcal{H}}$ for $f, g \in \mathcal{H}$.

iii) $\langle f, D_\theta f \rangle_{\mathcal{H}} = \| \nabla_\theta \int f(x) q_\theta(dx) \|^2 = \| \nabla_\theta \langle f, \mu_{q_\theta} \rangle_{\mathcal{H}} \|^2 \geq 0$. In particular, $D_\theta$ is a positive operator and hence its spectrum is contained in $[0, \infty)$.

iv) For $f \in \mathcal{H}$, we have $\langle D_\theta f, f \rangle_{\mathcal{H}} = \langle D(x, \cdot), f \rangle_{\mathcal{H}}$ with

$$D(y, y') := \iint (\partial_\theta k(G_\theta(z), y), \partial_\theta k(G_\theta(z'), y')) \nu(dz) \nu(dz')$$

, where $\partial_\theta k(G_\theta(z), y) = I_\theta G_\theta(z) \nabla x k(G_\theta(y), y)$. Equivalently

$$D(y, y') = \iint \text{Trace}(\nabla x k(G_\theta(z), y) \otimes \Gamma_\theta(z, z') \nabla x k(G_\theta(z'), y')) \nu(dz) \nu(dz').$$

### 3 A Novel Parametric Energy Regularization of MMD

Let us introduce a parametric energy regularization of MMD and this notion of discrepancy will play a central role in this paper. For parameters $\alpha, \beta \geq 0$, the regularized discrepancy between a given probability distribution $p$ on $\Omega$ and a parametric distribution $q_\theta \in \mathcal{P}_\Theta$ is defined by

$$\text{MMD}_{\alpha,\beta}(p, q_\theta) := \sup_{f \in E_{\alpha,\beta}} \left\{ \int_\Omega f(x) \, p(dx) - \int_\Omega f(x) \, q_\theta(dx) \right\}$$

(2)

with $E_{\alpha,\beta} := \left\{ f \in \mathcal{H} : \alpha \| \nabla_\theta \int f(x) q_\theta(dx) \|_{\mathbb{R}^p}^2 + \beta \| f \|_{\mathcal{H}}^2 \leq \frac{1}{2} \right\}$. The case $\alpha = 0$ and $\beta = 1/2$ corresponds to the MMD [17], while the case $\alpha = 1/2$ and $\beta = 0$ shares some similarity with the usual kernelized Sobolev discrepancy [31]. The main difference in this definition with the Sobolev discrepancy is that the parametric energy $\| \nabla_\theta \langle f, \mu_{q_\theta} \rangle_{\mathcal{H}} \|_{\mathbb{R}^p}^2 = \langle f, D_\theta f \rangle_{\mathcal{H}}$ is used in place of the standard energy $\| \nabla f \|_{L_2_{\theta}}^2$.

**Remark 1.** Note that our regularization for MMD while it shares similarities with WGAN-GP [18], it is different since our gradient penalty is with respect to the generator parameter whereas it is with respect to the input in WGAN-GP.

Hereafter, $I : \mathcal{H} \to \mathcal{H}$ denotes the identity operator. Then it follow from property iii) in Proposition 3 that $\alpha D_\theta + \beta I$ is invertible whenever $\alpha \geq 0$ and $\beta > 0$. Proposition 3 also allows us to express the constraint $E_{\alpha,\beta}$ in (2) as

$$E_{\alpha,\beta} = \left\{ f \in \mathcal{H} : 2 \langle f, (\alpha D_\theta + \beta I) f \rangle_{\mathcal{H}} \leq 1 \right\}.$$  

(3)

This constraint can be interpreted as a regularization through the following unconstrained formulation.
Proposition 4. Let \( \Delta_\theta(f) := \int f(x) \, p(dx) - \int f(x) \, q_\theta(dx) \). For \( \alpha \geq 0 \) and \( \beta > 0 \), we have
\[
\text{MMD}_{a,\beta}(p, q_\theta)^2 = \sup_{f \in \mathcal{H}} \left\{ \Delta_\theta(f) - \frac{\alpha}{2} \| \nabla_\theta \langle f, \mu_{q_\theta} \rangle \|_{\mathbb{R}^p}^2 - \frac{\beta}{2} \| f \|_{\mathcal{H}}^2 \right\} \\
= \frac{1}{2} \left\langle \mu_{p-\nu_\theta}, (\alpha D_\theta + \beta I)^{-1} \mu_{p-\nu_\theta} \right\rangle_{\mathcal{H}}.
\]
Moreover, the witness function \( f^* \) realizing the above supremum is given by:
\[
(\alpha D_\theta + \beta I) f^* = \mu_{p-\nu_\theta}.
\]

The next result shows that the regularized MMD \( \text{MMD}_{a,\beta} \) is upper bounded by the MMD, and gives a characterization on distributions for which the two discrepancies are the same.

Corollary 5. For \( \alpha \geq 0 \) and \( \beta > 0 \), we have
\[
\sqrt{2\beta} \text{MMD}_{a,\beta}(p, q_\theta) \leq \text{MMD}(p, q_\theta).
\]
In case \( \alpha > 0 \), the equality happens if and only if \( D_\theta \mu_{p-\nu_\theta} = 0 \).

4 Generative Adversarial Networks via Parametric Regularized Flows

Let \( p \) be the target distribution which is a probability measure on \( \Omega \). Consider the functional \( \mathcal{F}(q_\theta) = \frac{1}{2} \text{MMD}^2(p, q_\theta) = \frac{1}{2} \| \mu_{p-\nu_\theta} \|_{\mathcal{H}}^2 \). We now focus on the MMD GAN problem:
\[
\min_{q \in \mathcal{P}_\Omega} \mathcal{F}(q) = \min_{\theta \in \Theta} \mathcal{F}(q_\theta) \\
= \min_{\theta \in \Theta} \frac{1}{2} \| \mathbb{E}_p k(x, \cdot) - \mathbb{E}_{z \sim \nu_\theta} k(G_\theta(z), \cdot) \|_{\mathcal{H}}^2.
\]

This problem has been investigated in several works [3, 15, 20, 21, 31]. In this section we propose a new descent direction in the parameter space of the generator.

Continuous Descent. We consider the following dynamic for any sequence of functions \( f_t \in \mathcal{H}, t \geq 0 \):
\[
\frac{d \theta_t}{dt} = L_{\theta_t}(f_t) = \int J_{\theta_t} G_{\theta_t}(z') \nabla_x f_t(G_{\theta_t}(z')) v(dz').
\]

For a given \( z \in \mathcal{Z} \), the dynamic of the generator is as follows
\[
\frac{d G_{\theta_t}(z)}{dt} = J_{\theta_t} G_{\theta_t}(z)^\top \frac{d \theta_t}{dt}
= \int J_{\theta_t} G_{\theta_t}(z')^\top J_{\theta_t} G_{\theta_t}(z') \nabla_x f_t(G_{\theta_t}(z')) v(dz')
= \int \Gamma_{\theta_t}(z, z') \nabla_x f_t(G_{\theta_t}(z')) v(dz').
\]

While the dynamic of particles is usually given by velocities defined at each particle, the generator’s dynamic at a given \( z \) is the average of the mass corrected velocities of all other samples from the generator. The mass correction is driven by the matrix valued kernel \( \Gamma_{\theta_t} \) that defines a similarity in the hidden space \( \mathcal{Z} \). For example in particles descent such as Sobolev Descent [31] the dynamic of particles \( X_t \) is given by:
\[
\frac{d X_t}{dt} = \nabla_x f(X_t),
\]
and this simple advection dynamic is to be contrasted with the generator dynamic (7).

Using the dynamic of the generator in (7) and item iv) in Proposition 3, we also have the following dynamic of the mean embedding:

$$\frac{d}{dt}\mu_{\theta_t} = \frac{d}{dt} \int k(G_{\theta_t}(z),.)\nu(dz)$$

$$= \int \left< \nabla_x k(G_{\theta_t}(z),.), \frac{dG_{\theta_t}(z)}{dt} \right> \nu(dz)$$

$$= \int \left< \nabla_x k(G_{\theta_t}(z),.), \frac{d}{dt}f_t(G_{\theta_t}(z)) \right> \nu(dz)$$

$$= D_{\theta_t}f_t.$$  (8)

Given the dynamic of the mean embedding in (8) it is easy to derive the dynamic of the MMD distance:

$$\frac{dF(q_{\theta_t})}{dt} = \left< \mu_{p-q_{\theta_t}}, \frac{d}{dt}\mu_{q_{\theta_t}} \right> \|H\| = -\left< \mu_{p-q_{\theta_t}}, D_{\theta_t}f_t \right> \|H\|.  \tag{9}$$

Let us consider the following choices for the sequence $f_t$:

- **Witness functions of MMD.** In that case, we set $f_t = \mu_{p-q_{\theta_t}}$. Using the generator updates given in (5), we have therefore:

$$\frac{dF(q_{\theta_t})}{dt} = -\left< \mu_{p-q_{\theta_t}}, D_{\theta_t}\mu_{p-q_{\theta_t}} \right> \|H\| \leq 0.$$ 

This is a valid descent direction, and is similar in spirit to the MMD flows of [1]. Nevertheless as shown for the particles case in [1], it does not lead to convergence. In the discrete case, [1] introduced a noising scheme that has convergence guarantees.

- **Witness functions of MMD_{1,0}.** In that case, let us assume that solutions $f_t$ of $D_{\theta_t}f_t = \mu_{p-q_{\theta_t}}$ exist. Then by using $d\theta_t = L_{\theta_t}(f_t)dt$ we obtain:

$$\frac{dF(q_{\theta_t})}{dt} = -\left< \mu_{p-q_{\theta_t}}, \mu_{p-q_{\theta_t}} \right> = -2F(q_{\theta_t}).$$

While this seems to be the ideal choice as it gives us an exponential convergence, it comes with the caveat that $D_{\theta_t}$ may be singular and hence we have either no solution or infinitely many solutions for $f_t$. These derivations and the singularity issue of operator $D_{\theta_t}$ motivated the introduction of MMD_{\alpha,\beta}, and we consider hereafter its flows.

- **Witness functions of MMD_{\alpha,\beta}.** Let $f_t$ be the unique witness function of MMD_{\alpha,\beta} between $p$ and $q_{\theta_t} = (G_{\theta_t})_\#\nu$ given by

$$(\alpha D_{\theta_t} + \beta I)f_t = \mu_{p-q_{\theta_t}}.$$  (10)

Theorem 6 below gives the dynamic of the MMD when the generator parameters are updated according to Equation (5) with $f_t$ being the MMD_{\alpha,\beta} witness functions given in Equation (10).

**Theorem 6 (Parametric Regularized Flows Decrease the MMD Distance).** Assume that $\alpha, \beta > 0$. Then the dynamic (5)–(10) defined by the witness function of the parametric regularized MMD decreases the functional $F(q_{\theta_t})$:

$$\frac{dF(q_{\theta_t})}{dt} = -\frac{2}{\alpha} \left[ F(q_{\theta_t}) - \beta \text{MMD}_{\alpha,\beta}(p, q_{\theta_t})^2 \right] \leq 0.$$  \tag{11}

Moreover, we have $\frac{dF(q_{\theta_t})}{dt} < 0$ if and only if $D_{\theta_t}\mu_{p-q_{\theta_t}} \neq 0$.

We see from Theorem 6 that MMD_{\alpha,\beta} witness functions alleviate the singularity issue of $D_{\theta_t}$, but slows down the convergence by introducing a damping term that is proportional to MMD_{\alpha,\beta}^2.
5 Non-Asymptotic Convergence Of Gradient Descent In MMD GAN

In Section 4, we showed that MMD_β,α witness functions provide descent directions for continuous MMD GAN. In this section we turn to (discrete) gradient descent in the parameter space of the generator, and give non asymptotic convergence results for gradient descent in regularized MMD GANs.

### Discrete Descent Directions

We would like to identify directions of \( \theta \) along which the functional \( \mathcal{F}(q_\theta) \) decreases its value. For this, let us compute the rate \( \frac{d}{d\varepsilon} \mathcal{F}(q_{\theta+\varepsilon v}) \) for each vector \( v \in \mathbb{R}^p \).

**Lemma 7.** Let \( \theta \in \Theta \). Then for any vector \( v \in \mathbb{R}^p \), we have

\[
\frac{d}{d\varepsilon} \mathcal{F}(q_{\theta+\varepsilon v}) = -\langle \mu_{\varepsilon - q_{\theta+\varepsilon v}}, L^T_{\theta+\varepsilon v} v \rangle \mathcal{H} \quad \text{for any} \quad \varepsilon \geq 0.
\]

Lemma 7 implies that \( v \) is a descent direction of \( \mathcal{F}(q_{\theta}) \) if and only if \( \langle \mu_{\varepsilon - q_{\theta}}, L^T_{\theta} v \rangle \mathcal{H} > 0 \). The next result gives one such direction.

**Proposition 8.** Let \( \theta \in \Theta \), and assume that \( D_\theta \mu_{p-q_\theta} \neq 0 \). Let \( v^* = L_\theta f \) with \( f \in \mathcal{H} \) being the solution of \( (\alpha D_\theta + \beta I) f = \mu_{p-q_\theta} \). Then \( v^* \) is a descent direction of \( \mathcal{F}(q_\theta) \). Precisely, we have

\[
\frac{d}{d\varepsilon} \mathcal{F}(q_{\theta+\varepsilon v^*}) = -\left[ \alpha \| D_\theta f \|^2 \mathcal{H} + \beta \langle f, D_\theta f \rangle \mathcal{H} \right] < 0.
\]

In particular, \( \mathcal{F}(q_{\theta+\varepsilon v^*}) < \mathcal{F}(q_{\theta}) \) if \( \varepsilon > 0 \) is small enough.

### Discrete Time Descent for MMD GAN

Hereafter, we denote \( \| h \|_{\mathcal{H}} := \left( \sum_{i=1}^d |h_i|_\mathcal{H}^2 \right)^{\frac{1}{2}} \) for \( h = (h_1, ..., h_d) \in \mathcal{H}^d \) and \( \| A \| := (\sum_{i,j} a_{ij}^2)^{\frac{1}{2}} \) for a matrix \( A = (a_{ij}) \). The next result holds under the following extra conditions for \( k \) and \( G \):

\[
\| \nabla_x k(z_1, \cdot) - \nabla_x k(z_2, \cdot) \|_{\mathcal{H}} \leq \tilde{L} \| z_1 - z_2 \|, \quad (12)
\]

\[
\| J_\theta G_\theta(z) - J_\theta G_{\theta'}(z) \| \leq \tilde{D} \| \theta - \theta' \| \quad \text{(13)}
\]

with \( \mathbb{E}_p[\tilde{D}(z)] < \infty \).

In Theorem 9 below we find conditions under which we can achieve global convergence in MMD of gradient descent in MMD GAN. When the kernel is characteristic, this is equivalent to the global weak convergence of gradient descent in MMD GAN to the target distribution. Gradient descent for MMD GAN is given by the following updates: for all \( \ell \geq 1 \), the witness functions between \( p \) and \( q_{\theta_\ell} = (G_{\theta_\ell})^p \) update:

\[
f_\ell := (\alpha_\ell D_{\theta_\ell} + \beta_\ell I)^{-1} \mu_{\varepsilon - q_{\theta_\ell}} \quad \text{(14)}
\]

and the generator update,

\[
\theta_{\ell+1} := \theta_\ell + \varepsilon_\ell L_{\theta_\ell}(f_\ell) \quad \text{(15)}
\]

where \( \alpha_\ell, \beta_\ell \) is a sequence of regularization parameters, and \( \varepsilon_\ell \) is a sequence of learning rates.

**Theorem 9.** Assume that \( k \) and \( G \) satisfy (1) and (12)-(13). Let \( \lambda_i(\theta) > 0 \) be the smallest non-zero eigenvalue of \( D_\theta \), and define \( a(\theta, f) := 1 - \frac{\| P_{\text{Null}(D_\theta)} f \|_{\mathcal{H}}^2}{\| f \|_{\mathcal{H}}^2} \) with \( P_{\text{Null}(D_\theta)} \) being the projection to the null space of \( D_\theta \). Let \( \mathcal{F}(q_\theta) = \frac{1}{2}\text{MMD}(p, q_\theta)^2 \). Consider the gradient descent updates given in (14) and (15). Let \( 0 < \tau < 1 \) and \( \theta_1 \in \Theta \) be the starting point chosen such that

\[
a(\theta_1, f_1) > \tau. \quad \text{(16)}
\]
The sequence $\epsilon_\ell$ is chosen so that the following two conditions are satisfied for each $\ell$:
\begin{equation}
 a(\theta_{\ell+1}, f_{\ell+1}) > \tau \tag{17}
\end{equation}
and
\begin{equation}
 2C(2\beta_\ell)^{-1} \left( 1 + \sqrt{\mathcal{F}(q_{\theta_1})} \right) \leq \epsilon_\ell^{-1} \tag{18}
\end{equation}
with $C > 0$ depending only on the constants $C_1, C_2, C_3, C_4$ given in Lemma 17.

Under the condition (17) on $\epsilon_\ell$ we have $\tau < a(\theta, f_{\ell}) \leq 1$. Let $\chi_j := \frac{\lambda_j(\theta, f_{\ell})}{a_j(\theta, f_{\ell})} + \beta_j > 0$. Then we have:
\begin{equation*}
 \mathcal{F}(q_{\theta_{\ell+1}}) \leq \mathcal{F}(q_{\theta_1}) \exp(-\sum_{j=1}^{\ell} \epsilon_j \chi_j) \quad \forall \ell \geq 1.
\end{equation*}

In particular for $\alpha_\ell \leq \frac{1}{2}$ and $\beta_\ell = \alpha_\ell \lambda_1(\theta)$, we obtain $\chi_1 \geq 1$ and it follows that:
\begin{equation*}
 \mathcal{F}(q_{\theta_{\ell+1}}) \leq \mathcal{F}(q_{\theta_1}) \exp(-\sum_{j=1}^{\ell} \epsilon_j).
\end{equation*}

Consequently if $\sum_{j=1}^{\infty} \epsilon_j = +\infty$ (meaning that $\epsilon_j$ decays as $1/\sqrt{j}$ for e.g) and conditions (17) and (18) hold, then we obtain $\mathcal{F}(\theta_j) \to 0$ as $\ell \to \infty$. As we see from Theorem 9, not all learning rates are admissible. At a given iteration $\ell$, we select a learning rate $\epsilon_\ell$, so that $f_{\ell+1} \notin \text{Null}(D_{\theta_{\ell+1}})$ (ensured by condition (17)) and so that (18) holds as well. To understand condition (17), recall from Theorem 6 that having $f_{\ell}$ not in the null space of $D_{\theta_j}$ means that we have a strict descent. (It is easy to see that $f_{\ell} \notin \text{Null}(D_{\theta_j})$ if and only if $\mu_p - q_{\theta_j} \notin \text{Null}(D_{\theta_j})$).

### 6 Parametric Kernelized Flows for a General Functional

The flow of the MMD functional (i.e. $\frac{1}{2}\text{MMD}(p, q_\theta)^2$) analyzed in the previous sections is driven by the gradient of the witness function between $p$ and $q_\theta$ of the discrepancy $\text{MMD}_{p, q_\theta}$. In this section we discover a Riemannian structure on the statistical manifold of probability distributions and show that the continuous gradient descent in MMD GANs described in Section 4 coincides with the gradient flow of the functional with respect to this new geometric structure. We also develop a rigorous theory for treating gradient flows of general functionals and thus open a way for other types of variational inferences beyond GANs.

#### 6.1 Dynamic Formulation For MMD on a Statistical Manifold

The following result gives a dynamic formulation of MMD and allows us to discover a Riemannian structure associated to MMD. This is analogous to Benamou–Brenier dynamic formulation of the Wasserstein of order 2 [7]:
\begin{equation}
 W_2^2(p, q) = \inf_{\theta, f} \int_0^1 \int \| \nabla_x f_t(x) \|^2 q_t(dx) dt \\
 \text{s.t. } \frac{\partial \theta_t(x)}{\partial t} = -\text{div}(q_t \nabla_x f_t(x)) \quad q_0 = q, q_1 = p. \tag{19}
\end{equation}
The main difference is that their flows are with respect to the standard $L_2\mu_p$ energy, while ours as explained in Section 6.2, are driven by the parametric energy $\| \nabla_\theta [\langle f, \mu_{q_\theta} \rangle] \|^2$.

**Theorem 10 (Dynamic MMD on a Statistical Manifold).** Assume that for any $\theta_0, \theta_1 \in \Theta$, there exists a path $(\theta_t, f_t)_{t \in [0, 1]}$ such that $\theta_{t=0} = \theta_0, \theta_{t=1} = \theta_1, f_t \in \mathcal{H}$, and
\begin{equation}
 \partial_\theta \theta_t = L_{\theta_t} f_t \text{ and } D_{\theta_t} f_t = 2\mu_{q_{\theta_t} - q_{\theta_t}} \quad \forall t \in [0, 1]. \tag{20}
\end{equation}
Let $q_{\theta_0}$ and $q_{\theta_1}$ be two probability measures in $\mathcal{P}_\Theta$. Then we have the following dynamic form of MMD between distributions defined on the statistical manifold $\mathcal{P}_\Theta$:

$$\text{MMD}^2(q_{\theta_0}, q_{\theta_1}) = \min_{\theta_t, f_t} \left\{ \int_0^1 \left\| D_{\theta_t} f_t \right\|_{\mathcal{H}}^2 dt \right\},$$

where

$$\partial_t \theta_t = L_{\theta_t} f_t, f_t \in \mathcal{H}, \theta_{t=0} = \theta_0, \theta_{t=1} = \theta_1.$$

Theorem 10 is proven under Assumption 20 that guarantees the existence of a solution. This assumption is not realistic since $D_{\theta_t}$ can be singular. Nevertheless, we state this theorem to motivate the introduction in the next section of the dynamic form of a regularized MMD that alleviates this singularity issue.

### 6.2 Regularized MMD and Gradient Flows on a Statistical Manifold

Motivated by the result in Theorem 10 and to alleviate the singularity issue in Assumption (20), we define the following regularized version of MMD:

**Definition 11** (Regularized MMD on a Statistical Manifold). Let $\alpha, \beta > 0$. Define

$$d_{\alpha, \beta}(q_{\theta_0}, q_{\theta_1})^2 = \min_{\theta_t, f_t} \int_0^1 \left( \alpha \left\| D_{\theta_t} f_t \right\|_{\mathcal{H}}^2 + \beta \left\langle f_t, D_{\theta_t} f_t \right\rangle_{\mathcal{H}} \right) dt,$$

where

$$\partial_t \theta_t = L_{\theta_t} f_t, f_t \in \mathcal{H}, \theta_{t=0} = \theta_0, \theta_{t=1} = \theta_1.$$

Note that the regularization we introduced here is the parametric energy

$$\left\| \nabla_{\theta_t} \left[ \left\langle f_t, \mu_{\theta_t} \right\rangle_{\mathcal{H}} \right] \right\|_{\theta_t}^2 = \left\langle f_t, D_{\theta_t} f_t \right\rangle_{\mathcal{H}},$$

which plays a similar role as the kinetic energy in Benamou-Brenier’s formula. The evolution of $\theta_t$ in our form is analogous to the continuity equation in the $L_2$ dynamic form [7]. Conditions on the kernel and the generator family under which we can guarantee existence of the solution for this problem are out of the scope of this work, since our interest in this heuristic Riemannian structure is solely in order to define an appropriate tangent space and Riemannian metric tensor. We leave the analysis of $d_{\alpha, \beta}$ to a future work.

This dynamic formulation gives rise to the following Riemannian metric tensor on the tangent space of $\Theta$: for $\theta \in \Theta$, let

$$g_\theta(\xi_1, \xi_2) := \alpha \left\langle D_\theta \varphi_1, D_\theta \varphi_2 \right\rangle_{\mathcal{H}} + \beta \left\langle \varphi_1, D_\theta \varphi_2 \right\rangle_{\mathcal{H}}$$

where

$$\xi_i = L_\theta (\varphi_i) = \nabla_\theta \left[ \left\langle \varphi_i, \mu_{\theta_t} \right\rangle_{\mathcal{H}} \right] \in \mathbb{R}^p \text{ with } \varphi_i \in \mathcal{H} \text{ (i = 1, 2)}.\$$

We denote $g_\theta(\xi_1, \xi_2) = g_\theta(\xi_2, \xi_1)$ due to the symmetry of $D_\theta$ (see property ii) of Proposition 3). Then it follows that

$$d_{\alpha, \beta}(q_{\theta_0}, q_{\theta_1})^2 = \min_{\theta_t, f_t} \left\{ \int_0^1 g_\theta(\partial_t \theta_t, \partial_t \theta_t) dt \right\},$$

where

$$\partial_t \theta_t = L_{\theta_t} f_t, f_t \in \mathcal{H}, \theta_{t=0} = \theta_0, \theta_{t=1} = \theta_1.$$

Let us assume that $\alpha, \beta > 0$ from now on. For a functional $\mathcal{F}: \mathcal{P}_\Theta \to \mathbb{R}$, let $\nabla_{d_{\alpha, \beta}} \mathcal{F}(q_\theta)$ denote the gradient of $\mathcal{F}$ with respect to the metric $d_{\alpha, \beta}$. That is, $\nabla_{d_{\alpha, \beta}} \mathcal{F}(q_\theta)$ is a vector in $\mathbb{R}^p$ satisfying

$$\frac{d \mathcal{F}(q_\theta)}{dt} \bigg|_{t=0} = g_{d_{\alpha, \beta}} \left( \nabla_{d_{\alpha, \beta}} \mathcal{F}(q_\theta), \xi \right)$$

for every differentiable curve $t \mapsto \theta_t \in \Theta$ with $\theta_{t=0} = \theta$ and $\partial_t \theta_t \big|_{t=0} = \xi = L_\theta \varphi$ for some $\varphi \in \mathcal{H}$. The following theorem shows us how to compute such gradient.
Theorem 12. Let $\mathcal{F}(q_\theta)$ be a functional depending only on the kernel mean embedding of $q_\theta$. Precisely, assume that $\mathcal{F}(q_\theta) = H(\mu_\theta)$ for some functional $H$ with the chain rule property
\[
\partial_\theta [H(\mu_\theta)] = \langle h_\theta, \partial_\theta [\mu_\theta] \rangle_H
\] (22)
for some function $h_\theta \in \mathcal{H}$ and for all $\theta \in \Theta$. Then the gradient of $\mathcal{F}$ w.r.t. the discrepancy $d_{a,\beta}$ is given by
\[
\text{grad}_{d_{a,\beta}} \mathcal{F}(q_\theta) = L_\theta u, \quad \text{where}
\]
\[
(aD_\theta + \beta I) u = h_\theta. \tag{23}
\]
Let $\mathcal{F}(q_\theta)$ be the functional as in Theorem 12, and consider the gradient flow of $\mathcal{F}(q_\theta)$ with respect to $d_{a,\beta}$. We note that this is a gradient regularized flow. According to Theorem 12, the equation of this flow is given by
\[
\partial_t \theta_t = -\text{grad}_{d_{a,\beta}} \mathcal{F}(q_{\theta_t}) = -L_{\theta_t} u_t, \tag{24}
\]
where
\[
(aD_{\theta_t} + \beta I) u_t = h_{\theta_t}. \tag{25}
\]
The following proposition shows that these gradient flows are indeed descent directions of the functional defined on the statistical manifold $\mathcal{P}_\Theta$:

Proposition 13. Along the gradient flow (24)-(25) of $\mathcal{F}(q_\theta)$, we have
\[
\frac{d}{dt} \mathcal{F}(q_{\theta_t}) = -\left[ a \|D_{\theta_t} u_t\|^2_{\mathcal{H}} + \beta \|L_{\theta_t} u_t\|^2 \right] \\
= -\frac{1}{a} \left[ \|h_{\theta_t}\|_{\mathcal{H}}^2 - \beta \left( \langle h_{\theta_t}, (aD_{\theta_t} + \beta I)^{-1} h_{\theta_t} \rangle_{\mathcal{H}} \right) \right] \\
\leq 0,
\]
where $h_{\theta}$ is defined by (22). Moreover, we have $\frac{d\mathcal{F}(q_{\theta_t})}{dt} < 0$ if and only if $D_{\theta_t} h_{\theta_t} \neq 0$.

Intuition on the role of $D_{\theta}$ in the gradient flow. The operator $D_{\theta}$ plays a central role in our framework and we give here an intuitive interpretation of its role from the gradient flow lens. Let $\{ (\lambda_j(\theta), v_j(\theta)) \}_{j=1}^{\infty}$ be the eigenvalues and eigenfunctions of the operator $D_{\theta}$. Then as we have $u_t = \sum_{j=0}^{\infty} \frac{1}{a \lambda_j(\theta_t) + \beta} \langle h_{\theta_t}, v_j(\theta_t) \rangle_{\mathcal{H}} v_j(\theta_t)$, the flow equation can be written as follows: $\partial_t \theta_t = -\text{grad}_{d_{a,\beta}} \mathcal{F}(q_{\theta_t}) = -\sum_{j=0}^{\infty} \frac{1}{a \lambda_j(\theta_t) + \beta} \langle h_{\theta_t}, v_j(\theta_t) \rangle_{\mathcal{H}} L_{\theta_t} (v_j(\theta_t))$. The eigenfunctions of $D_{\theta_t}$ provide the descent directions $L_{\theta_t} (v_j(\theta_t))$, that are linearly combined according to the similarity of $v_j(\theta_t)$ and $h_{\theta_t}$ and weighted by a factor $1/(a \lambda_j(\theta_t) + \beta)$. Small eigenvalues are noisy directions and spectral filtering them via $a$ and $\beta$ favors descent directions with larger eigenvalues.

6.3 Gradient Flows of Particular Functionals: MMD GAN as Gradient Flow

MMD GAN as a Gradient Flow w.r.t. $d_{a,\beta}$. The next result shows that the flow (5)-(10) of the parametric gradient regularized MMD GAN coincides with the gradient flow of $\mathcal{F}(q_\theta) = \frac{1}{2} \text{MMD}(p, q_\theta)^2$ with respect to $d_{a,\beta}$.

Corollary 14. For $\mathcal{F}(q_\theta) = \frac{1}{2} \text{MMD}(p, q_\theta)^2$, we have $\text{grad}_{d_{a,\beta}} \mathcal{F}(q_\theta) = L_\theta u$ with $(aD_\theta + \beta I) u = -\mu_{p-q_\theta}$. Consequently, the parametric regularized flow (5)-(10) on the statistical manifold is the gradient flow of $\mathcal{F}$ with respect to $d_{a,\beta}$.
Consider the dynamic parametric gradient flows of functionals defined on the statistical manifold w.r.t. $d_{\alpha,\beta}$.

In this section we analyze the convergence properties of the kernelized gradient regularizers. We show that there exists a continuous function $\gamma$ such that there is locally stable. Even if $\gamma$ is a variant of a gradient penalty on the parameter space of the discriminator is locally stable. Even if the discriminator considered in [27] and the discriminator considered in [28, 36] that these gradient regularizers ensure stability and convergence of the min/max game. [33] showed that GANs with a variant of a gradient penalty on the parameter space of the discriminator is locally stable. Even

**Proof.** This follows immediately from Theorem 12 noting that

$$\partial_{\theta}[F(q_\theta)] = -\left< \mu_{p-q_\theta}, \partial_{\theta}[\mu_{q_\theta}] \right>_H.$$ 

\[\square\]

**Gradient flows of Generic Functionals on the Statistical Manifold.** Our framework is not limited to the MMD functional. In the following corollary we exhibit additional examples of functional $F(q_\theta)$ defined on the statistical manifold along with their gradient flows w.r.t. $d_{\alpha,\beta}$.

**Corollary 15.**

- For the (potential) energy functional $F_1(q_\theta) = \int V(x)q_\theta(dx)$ with $V \in H$, we have $\text{grad} F_1(q_\theta) = L_0 u$, where $(\alpha D_\theta + \beta I)u = V$.

- For the (entropy) functional $F_2(q_\theta) = \int f(\mu_{q_\theta}(x))dx$ with $f : \mathbb{R} \to \mathbb{R}$ being continuously differentiable, we have $\text{grad} F_2(q_\theta) = L_0 u$, where $(\alpha D_\theta + \beta I)u = f'(\mu_{q_\theta}(x))k(x,.)dx$.

- For the (interaction) functional $F_3(q_\theta) = \int f(x)g(y)q_\theta(dx)q_\theta(dy)$ with $f, g \in H$, we have $\text{grad} F_3(q_\theta) = L_0 u$, where $(\alpha D_\theta + \beta I)u = \left< f, \mu_{q_\theta} \right>_H g + \left< g, \mu_{q_\theta} \right>_H f$.

**Continuous Time Descent** In this section we analyze the convergence properties of the kernelized parametric gradient flows of functionals defined on the statistical manifold w.r.t. $d_{\alpha,\beta}$. The following proposition studies the convergence behavior of the parametric flows.

**Proposition 16 (Convergence up to a barrier).** Let $F(q_\theta)$ be the functional as in Theorem 12. Assume that there exists a continuous function $\gamma : \Theta \to \mathbb{R}$ such that

$$\|h_\theta\|_H^2 \geq \gamma(\theta) F(q_\theta) \quad \forall \theta \in \Theta. \quad (26)$$

Consider the dynamic $t \in [0, +\infty) \to \theta_t \in \Theta$ of the gradient flow (24)–(25). Then we have for every $t \geq 0$:

$$F(q_{\theta_0}) \leq F(q_{\theta_t}) e^{-\int_0^t \lambda_1(\theta_s) \text{d}s}, \quad (27)$$

where $\lambda_1(\theta)$ and $a(\theta, u)$ are defined in Theorem 9.

**Remark 2.** Note that condition (26) is satisfied by the MMD, for $\gamma(\theta) = 2$, since $h_\theta = -\mu_{p-q_\theta}$, and hence $\|h_\theta\|_H^2 = \gamma(\theta) F(q_\theta)$.

7 Related Work

**MMD GAN.** Since their introduction in [16], many cost functions have been proposed for training GANs. Related to our work is MMD GAN introduced in [15, 21] and later improved in [20].

**Gradient Regularized GANs.** GAN’s training is notoriously known to be unstable. Wasserstein GAN [4] tackled that issue by considering $W_1$ as a loss function for training. Imposing lipochitizity in practice is challenging and a gradient penalty in the input space was introduced in WGAN-GP [18] as means to impose lipochitizity. Sobolev GAN [30] connected this gradient penalty to advection and semi-Sobolev norms. The work [2] considered this input gradient regularizer in MMD GANs.

Closely related to our study are the gradient penalties on the parameter space of the generator and the discriminator considered in [27]. It was demonstrated in [28, 36] that these gradient regularizers ensure stability and convergence of the min/max game. [33] showed that GANs with a variant of a gradient penalty on the parameter space of the discriminator is locally stable. Even
though these works studied the stability of the min/max game and its convergence to a saddle point, they did not show the global convergence of the discrete gradient flow in the distributional sense which is what we prove in this paper thanks to the newly proposed Riemannian structure.

Gradient Flows. Wasserstein $\mathcal{W}_2$ flows for minimizing functionals over probabilities (see the excellent introduction [37]) are related to our work. These flows are non parametric and are given by the continuity equation. Recently Wasserstein flows were extended to statistical manifold [10], and a kernelized Wasserstein natural gradient flow was introduced in [1]. Kernelized particle flows such as Stein Descent [14, 23, 24], Sobolev Descent [31] and MMD flows [3] are not defined on a statistical manifold and only act on the particle level. [14, 23] introduce similar Riemannian structures to ours for the Stein geometry, nevertheless they are not defined on a statistical manifold, it would be interesting to derive a dynamical form of the Stein metric on a manifold of parametric explicit densities. [6] studied minimum stein estimators and introduced a natural Stein gradient, it would be interesting to connect their study to a definition of an appropriate dynamic Stein structure on a parametric manifold.

8 Numerical Experiments

(a) Trajectories of Flows for $\alpha = 0$: Euclidean Gradients Flows

(b) MMD Loss

(c) Trajectories of Flows for $\alpha = 100$: Kernelized Gradients Flows w.r.t. $d_{\alpha, \beta}$

(d) MMD Loss

Figure 1: Trajectories of Kernelized Gradient flows of the MMD functional for $\alpha = 0$ (no gradient regularization) and $\alpha = 100$. It is clear that the Riemannian structure induced by $d_{\alpha, \beta}$, $\alpha > 0$ guarantees the convergence, while GAN suffer from cycles and mode collapse for $\alpha = 0$.

We consider a finite dimensional RKHS defined by a random feature map [5, 35] $\Phi(x) : \Omega \rightarrow \mathbb{R}^m$. $\Phi$ in our case is a 4 layers Relu Network with hidden dimension $m = 512$, with weights sampled from standard Gaussian and then fixed [12]. The space $\mathcal{H} = \{ f(x) = \langle w, \Phi(x) \rangle, w \in \mathbb{R}^m \}$.

MMD GAN as a Kernelized Gradient Flow. In parametric gradient regularized MMD GANs, we find the MMD$_{\alpha, \beta}(p, q_{\theta_t})$ witness function $f_t$ between $p$ and $q_{\theta_t}$, and then update the generator according to: $\theta_{t+1} = \theta_t + \epsilon_t L_{\theta_t} f_t$. We showed that this coincides exactly with the gradient flow of the MMD functional w.r.t. the geometric structure $d_{\alpha, \beta}$ introduced in this paper, and we proved its global convergence under mild assumptions. We show here an example, where the target distribution is a two dimensional mixture of Gaussians with 8 modes. In this example, $Z$ is 256 dimensional space and $\nu$ is standard Gaussian on $Z$. The generator $G_0$ is a 2 layer Relu Network (hidden size 128) and two dimensional output. We fix the mini-batch size in the training to 512, the learning rate of the witness function and generator is set to $1e^{-4}$. We train the witness function.
\( f_t \) of MMD_{\alpha, \beta} with stochastic gradient (RmsProp \[39\]) for 5 iterations. Note that in this case only the last linear layer is updated in the witness function, and \( \Phi \) is kept fixed. We then update the parameter \( \theta \) with gradient descent on \(-E_{q_{\theta}} f_t\). We use also RmsProp to ensure that the learning rates are adaptive. Note that given the witness function \( f_t \), the discrete flow update given in Eq. (15) is exactly the gradient descent update on \(-E_{q_{\theta}} f_t\).

We give in Figure 1 the trajectories of the flows for \( \alpha = 100 \) and \( \alpha = 0 \) for \( L = 100K \) iterations. Since in our implementation (Appendix E) we use stochastic gradient for learning the witness function \( f_t \), the desired regularization effect of \( \beta \) is ensured by early stopping and SGD \[8, 41\]. The case \( \alpha = 100 \) corresponds to the gradient flow w.r.t. Riemannian structure \( d_{\alpha, \beta} \), the case \( \alpha = 0 \) corresponds to unregularized MMD GAN that uses Euclidean gradients on the objective \( \text{MMD}(p, q_{\theta}) \) \[15, 20, 21\]. We see from Figure 1 that the kernelized flows induced by \( d_{\alpha, \beta} \) for \( \alpha > 0 \) ensure graceful convergence of the generator to the target distribution as predicted by Theorem 9, while GAN suffers from cycles and mode collapse for \( \alpha = 0 \).

In Appendix F, we give trajectories for neural witness functions (i.e. \( \Phi \) is learned as well), and we see similar behavior to the fixed kernel. We leave for future work the extension of \( d_{\alpha, \beta} \) and its gradient flows to neural function spaces as in \[11, 19, 26\]. Analysing the dynamic of the min-max optimization of parametric gradient regularized MMD GAN descent in the neural case will be interesting to conduct in the spirit of \[13\].

9 Conclusion

We propose an energy regularized gradient descent to MMD GAN training and derive a condition guaranteeing its global convergence. We demonstrate that the resulting flow coincides with the gradient flow of MMD with respect to a newly proposed Riemannian structure on the statistical manifold of probability distributions. Our investigation deepens the role of gradient regularization in GANs. Future directions include more understanding about the relationship between the static discrepancy and the dynamic discrepancy introduced in this paper, and investigation of other variational problems on a statistical manifold using the proposed Riemannian structure.

A Proofs

The appendix parallels the paper in terms of sections and contains proofs of results presented within each Section.

A.1 Preliminaries

Proof of Proposition 3. The proof follows from noting that \( q_\theta = (G_\theta)_\theta v \) and \( L_\theta(f) = \nabla_\theta \int f(x) q_\theta(dx) = \nabla_\theta \langle f, \mu_\theta \rangle_H \).

[i] \( L_\theta \) and \( L_\theta^\top \) are adjoint operators:

\[
\langle L_\theta(f), v \rangle = \left\langle \int J_\theta G_\theta(z) \nabla f(G_\theta(z)) v(dz), v \right\rangle \\
= \int v^\top J_\theta G_\theta(z) \nabla f(G_\theta(z)) v(dz) \\
= \int \left\langle \nabla f(G_\theta(z)), J_\theta G_\theta(z)^\top v \right\rangle v(dz) \\
= \left\langle f, \int \left( \nabla_k(G_\theta(z), \cdot), J_\theta G_\theta(z)^\top v \right) v(dz) \right\rangle_H \\
= \left\langle f, L_\theta^\top v \right\rangle_H.
\]

[ii] \( D_\theta \) is symmetric, i.e., \( \langle D_\theta f, g \rangle_H = \langle f, D_\theta g \rangle_H \) for \( f, g \in H \).

\[
\langle D_\theta f, g \rangle_H = \langle L_\theta^\top L_\theta f, g \rangle_H \\
= \langle L_\theta f, L_\theta g \rangle_H \text{ (applying (i))} \\
= \langle f, L_\theta^\top L_\theta g \rangle_H \text{ (applying (i) again)} \\
= \langle f, D_\theta g \rangle_H
\]

[iii] \( \langle f, D_\theta f \rangle_H = \| \nabla_\theta \| (\langle f, \mu_\theta \rangle_H) \|^2 \geq 0 \). In particular, \( D_\theta \) is a positive operator and hence its spectrum is contained in \([0, \infty)\).

\[
\langle f, D_\theta f \rangle_H = \langle L_\theta f, L_\theta f \rangle = \| L_\theta f \|^2 = \left\| \int J_\theta G_\theta(z) \nabla f(G_\theta(z)) v(dz) \right\|^2 \\
= \left\| \int \nabla \theta f(G_\theta(z)) v(dz) \right\|^2 \\
= \left\| \int \left( \nabla f(G_\theta(z), \cdot), J_\theta G_\theta(z)^\top v \right) v(dz) \right\|_H^2 \\
= \left\| \nabla_\theta \left( f, \int k(G_\theta(z), \cdot) v(dz) \right) \right\|_H^2 \text{ (by regularity of the kernel and linearity)} \\
= \left\| \nabla_\theta \left( f, \mu_\theta \right) \right\|_H^2
\]

(iv) For \( f \in H \), we have \( (D_\theta f)(x) = \langle D(x, \cdot), f \rangle_H \) with

\[
D(y, y') := \iint (\partial_\theta k(G_\theta(z), y), \partial_\theta k(G_\theta(z'), y')) v(dz) v(dz')
\]
Proof of Corollary 5. Since the above supremum is attained at the function \(f\), we can apply standard duality result [25, Thm. 8.7.1] to obtain

\[
\langle f, D_\theta \mathcal{G} \rangle_{\mathcal{H}} = \langle L_\theta f, L_\theta \mathcal{G} \rangle
\]

hence we identify the operator \(D_\theta\).

\[\square\]

### A.2 Parametric Energy Regularization of MMD

Proof of Proposition 4. It follows from the fact \(f(x) = \langle f, (x, \cdot) \rangle_{\mathcal{H}}\) that \(\int f(x) p(dx) = \langle f, \mu_{\theta} \rangle_{\mathcal{H}}\) for \(f \in \mathcal{H}\). This and definition (2) gives \(\text{MMD}_{a,\beta}(p, q_\theta) = \sup_{f \in E_{a,\beta}} \langle f, \mu_{\theta} - q_\theta \rangle_{\mathcal{H}}\). Then as the quadratic form in (3) is convex in \(f \in \mathcal{H}\) and Slater’s condition holds due to \(2 \langle f, (aD_{\theta} + \beta I)f \rangle_{\mathcal{H}} - 1 < 0\) when \(f = 0\), we can apply standard duality result [25, Thm. 8.7.1] to obtain

\[
\text{MMD}_{a,\beta}(p, q_\theta) = \min_{\gamma \geq 0} \left\{ \langle f, \mu_{\theta} - q_\theta \rangle_{\mathcal{H}} + \gamma \left[ 1 - 2 \langle f, (aD_{\theta} + \beta I)f \rangle_{\mathcal{H}} \right] \right\}
\]

Since the above supremum is attained at the function \(f\) satisfying \(\mu_{\theta} - q_\theta = 4\gamma(aD_{\theta} + \beta I)f\), we further get

\[
\text{MMD}_{a,\beta}(p, q_\theta) = \min_{\gamma \geq 0} \left\{ \frac{1}{8\gamma} \left[ \mu_{\theta} - q_\theta, (aD_{\theta} + \beta I)^{-1}\mu_{\theta} - q_\theta \right]_{\mathcal{H}} + \gamma \right\}
\]

By the same reasoning, we also have

\[
\sup_{f \in \mathcal{H}} \left\{ \int f(x) p(dx) - \int f(x) q_\theta(dx) - \frac{\alpha}{2} \left\| \nabla_{\theta}(f, \mu_{\theta}) \right\|_{\mathcal{H}}^2 - \frac{\beta}{2} \| f \|_{\mathcal{H}}^2 \right\}
\]

\[
= \sup_{f \in \mathcal{H}} \langle f, \mu_{\theta} - q_\theta \rangle_{\mathcal{H}} - \frac{1}{2} \langle f, (aD_{\theta} + \beta I)f \rangle_{\mathcal{H}} = \frac{1}{2} \langle \mu_{\theta} - q_\theta, (aD_{\theta} + \beta I)^{-1}\mu_{\theta} - q_\theta \rangle_{\mathcal{H}}
\]

and the witness function realizing this supremum is given by:

\[
(aD_{\theta} + \beta I)f^* = \mu_{\theta} - q_\theta.
\]

This together with (28) gives the conclusion of the proposition.

\[\square\]

Proof of Corollary 5. By Proposition 4, we have

\[
\text{MMD}(p, q_\theta)^2 - 2\beta \text{MMD}_{a,\beta}(p, q_\theta)^2 = \| \mu_{\theta} - q_\theta \|^2_{\mathcal{H}} - \beta \langle \mu_{\theta} - q_\theta, f^* \rangle_{\mathcal{H}} = \langle \mu_{\theta} - q_\theta, \mu_{\theta} - q_\theta - \beta f^* \rangle_{\mathcal{H}}.
\]
But equation (4) for $f^*$ implies that $\mu_{p-q_0} - \beta f^* = \alpha D_\theta f^*$. Therefore, we obtain

$$\text{MMD}(p, q_0)^2 - 2\beta \text{MMD}_{\alpha, \beta}(p, q_0)^2 = \alpha \langle \mu_{p-q_0}, \alpha D_\theta f^* \rangle_\mathcal{H} \tag{29}$$

$$= \alpha \langle (\alpha D_\theta + \beta I) f^*, D_\theta f^* \rangle_\mathcal{H} = \alpha \left[ \alpha \| D_\theta f^* \|_\mathcal{H}^2 + \beta (f^*, D_\theta f^*)_\mathcal{H} \right] \geq 0.$$ 

This in particular gives the first conclusion of the corollary. When $\alpha > 0$, it also shows that the equality happens if and only if $D_\theta f^* = 0$. We next claim that $D_\theta f^* = 0$ is equivalent to $D_\theta \mu_{p-q_0} = 0$. Indeed, if $D_\theta f^* = 0$ then it follows from (4) that $\mu_{p-q_0} = \beta f^*$ and hence $D_\theta \mu_{p-q_0} = \beta D_\theta f^* = 0$. Conversely, if $D_\theta \mu_{p-q_0} = 0$ then we obtain from (4) that $\alpha D_\theta (D_\theta f^*) + \beta D_\theta f^* = 0$ yielding $\alpha \langle D_\theta (D_\theta f^*), D_\theta f^* \rangle_\mathcal{H} + \beta \langle D_\theta f^*, D_\theta f^* \rangle_\mathcal{H} = 0$. As the two terms are nonnegative, this only happens if $D_\theta f^* = 0$. Thus we have proved the claim and the proof is complete. \qed

### A.3 Generative Adversarial Networks via Parametric Regularized Flows

**Proof of Theorem 6.** From the definition of $\mathcal{F}$ and by using (8), we have

$$\frac{d\mathcal{F}(q_{\theta t})}{dt} = \left\langle \mu_{p-q_{\theta t}} - \frac{d}{dt} \mu_{q_{\theta t}} \right\rangle_\mathcal{H} = - \left\langle \mu_{p-q_{\theta t}}, \theta_t f_t \right\rangle_\mathcal{H}.$$ 

But from the identity (29) we obtain

$$\left\langle \mu_{p-q_{\theta t}}, \theta_t f_t \right\rangle_\mathcal{H} = \frac{2}{\alpha} \left[ \mathcal{F}(q_{\theta t}) - \beta \text{MMD}_{\alpha, \beta}(p, q_{\theta t})^2 \right].$$

Therefore, we conclude that the equality in (11) holds. On the other hand, the nonpositivity in (11) and the strict inequality assertion are just a consequence of Corollary 5. \qed

### B Non-Asymptotic Convergence Of Gradient Descent In MMD GAN

**Proof of Lemma 7.** It is easy to see that

$$\text{MMD}(p, q)^2 = \langle \mu_q - \mu_p, \mu_q - \mu_p \rangle_\mathcal{H} = \int \int k(x, y)q(dx)q(dy) - 2 \int \mu_p(x)q(dx) + \| \mu_p \|^2_\mathcal{H}. $$

It follows that

$$\frac{d}{dt} \mathcal{F}(q_{\theta t+\nu}) = \frac{1}{2} \frac{d}{dt} \int \int k(G_{\theta t+\nu}(z), G_{\theta t+\nu}(z'))v(dz)v(dz') - \frac{d}{dt} \int \mu_p(G_{\theta t+\nu}(z))v(dz)$$

$$= \frac{1}{2} \left[ \int \langle \nabla_x k(G_{\theta t+\nu}(z), G_{\theta t+\nu}(z')), I_{\theta t+\nu}G_{\theta t+\nu}(z)^\top v \rangle v(dz)v(dz') \right.$$ 

$$+ \int \langle \nabla_y k(G_{\theta t+\nu}(z), G_{\theta t+\nu}(z')), I_{\theta t+\nu}G_{\theta t+\nu}(z')^\top v \rangle v(dz)v(dz') \big]$$

$$- \int \langle \nabla \mu_p(G_{\theta t+\nu}(z)), I_{\theta t+\nu}G_{\theta t+\nu}(z)^\top v \rangle v(dz).$$

Since $\nabla_x k(z, z') = \nabla_y k(z', z)$ due to the symmetry of $k(x, y)$, we deduce that

$$\frac{d}{dt} \mathcal{F}(q_{\theta t+\nu}) = \int \langle \nabla_x k(G_{\theta t+\nu}(z), G_{\theta t+\nu}(z')), I_{\theta t+\nu}G_{\theta t+\nu}(z)^\top v \rangle v(dz)v(dz')$$

$$- \int \langle \nabla \mu_p(G_{\theta t+\nu}(z)), I_{\theta t+\nu}G_{\theta t+\nu}(z)^\top v \rangle v(dz)$$

$$= \int (L_{\theta t+\nu}^\top v)(G_{\theta t+\nu}(z'))v(dz') - \langle L_{\theta t+\nu}^\top v, v \rangle.$$
Observe that as $L_\theta^T v \in \mathcal{H}$, we have $(L_\theta^T v)(G_\theta(z')) = \left<k(G_\theta(z'), \cdot), L_\theta^T v, \right>_\mathcal{H}$, which implies that 

\[
\int (L_\theta^T v)(G_\theta(z')) v(dz') = \left< \int k(G_\theta(z'), \cdot) v(dz'), L_\theta^T v, \right>_\mathcal{H} = \left< \mu_{q_\theta}, L_\theta^T v, \right>_\mathcal{H}.
\]

Thus we can rewrite the above expression as

\[
\frac{d}{d\varepsilon} \mathcal{F}(\varepsilon) = \left< \mu_{\varepsilon}, L_{\varepsilon}^T L_\theta^T v, \right>_\mathcal{H} - \left< \varepsilon L_{\varepsilon}^T L_\theta^T v, \right>_\mathcal{H}.
\]

Proof of Proposition 8. From Lemma 7 and by our choice of $v^*$ we get

\[
\frac{d}{d\varepsilon} \mathcal{F}(\varepsilon) = \left< \mu_{-\varepsilon}, L_{\varepsilon}^T L_\theta f, \right>_\mathcal{H} - \left< \varepsilon L_{\varepsilon}^T L_\theta f, \right>_\mathcal{H} = -\left< \varepsilon \mu_{-\varepsilon}, L_\theta^T v, \right>_\mathcal{H}.
\]

Since $D_\theta \mu_{-\varepsilon} \neq 0$, we have from the proof of Corollary 5 that $D_\theta f \neq 0$. Therefore, the above expression is negative, i.e., $v^*$ is a descent direction.

\[\Box\]

B.1 Discrete time descent for MMD GAN

In order to prove Theorem 9 we need two auxiliary lemmas. The first one is:

**Lemma 17.** Assume that $k$ and $G$ satisfy (1) and (12)–(13). Then we have for any $\theta \in \Theta$, $\varepsilon \geq 0$, and $v \in \mathbb{R}^d$ that

\[
\|\mu_{\varepsilon \theta + \varepsilon \theta}, \|_H \leq C_1 \|v\|, \quad \|L_{\theta + \varepsilon \theta}^T v\|_H \leq C_2 \|v\|,
\]

\[
\|L_{\varepsilon \theta + \varepsilon \theta}^T L_\theta^T v\|_H \leq (C_3 + C_4) \varepsilon \|v\|^2,
\]

where $C_1 := LE_v[D(z)]$, $C_2 := \sqrt{d} LE_v[D(z)]$, $C_3 := \sqrt{d} LE_v[D(z)^2]$, and $C_4 := \sqrt{d} LE_v[D(z)]$.

**Proof.** We have

\[
\|\mu_{\varepsilon \theta + \varepsilon \theta}\|_H = \left< \int [k(G_\theta(z), \cdot) - k(G_{\theta + \varepsilon \theta}(z), \cdot)] v(dz), \right>_H = \int \left< k(G_\theta(z), \cdot) - k(G_{\theta + \varepsilon \theta}(z), \cdot), \right>_H v(dz).
\]

Hence by using Lipschitz condition (1), we get

\[
\|\mu_{\varepsilon \theta + \varepsilon \theta}\|_H \leq L \varepsilon \|v\| \int D(z)v(dz) =: C_1 \|v\|.
\]

In the following calculations, we use the observation that if $h = (h_1, ..., h_d) \in \mathcal{H}^d$ and $b \in \mathbb{R}^d$ then

\[
\|h, b\|_H = \left< \sum_{i=1}^d h_i b_i, \right>_H \leq \left< \sum_{i=1}^d \|h_i\| \|b_i\|, \right>_H \leq \left( \sum_{i=1}^d \|h_i\|^2 \right)^{\frac{1}{2}} \left( \sum_{i=1}^d \|b_i\|^2 \right)^{\frac{1}{2}} = \|h\| \|b\|.
\]

Also note that condition (1) implies that

\[
\|\nabla_x k(x, \cdot)\|_H \leq \sqrt{d} L \quad \text{and} \quad \|J_\theta G_\theta(z)\| \leq \sqrt{d} D(z).
\]

We next have

\[
\|L_{\theta + \varepsilon \theta}^T v\|_H \leq \left< \int [\nabla_x k(G_{\theta + \varepsilon \theta}(z), \cdot), J_{\theta + \varepsilon \theta} G_{\theta + \varepsilon \theta}(z) v(dz), \right>_H \leq \int \left< \nabla_x k(G_{\theta + \varepsilon \theta}(z), \cdot), J_{\theta + \varepsilon \theta} G_{\theta + \varepsilon \theta}(z) v(dz), \right>_H \leq \|v\| \int \|\nabla_x k(G_{\theta + \varepsilon \theta}(z), \cdot)\|_H \|J_{\theta + \varepsilon \theta} G_{\theta + \varepsilon \theta}(z)\| \|v(dz), \right>_H \leq \sqrt{d} L \|v\| \int D(z)v(dz) =: C_2 \|v\|.
\]
Finally, observe that
\[
\left\| \left( L_{\theta+\epsilon v}^\top - L_{\theta}^\top \right) v \right\|_{\mathcal{H}} = \left\| \int A_{\theta}(z, \cdot) v(dz) \right\|_{\mathcal{H}} \leq \int \left\| A_{\theta}(z, \cdot) \right\|_{\mathcal{H}} v(dz),
\]
where
\[
A_{\theta}(z, \cdot) := \langle \nabla x k(G_{\theta+\epsilon v}(z), \cdot), J_{\theta+\epsilon v} G_{\theta+\epsilon v}(z)^\top v \rangle - \langle \nabla x k(G_{\theta}(z), \cdot), J_{\theta} G_{\theta}(z)^\top v \rangle
\]
\[
= \left( \nabla x k(G_{\theta+\epsilon v}(z), \cdot) - \nabla x k(G_{\theta}(z), \cdot) \right) J_{\theta+\epsilon v} G_{\theta+\epsilon v}(z)^\top v
\]
\[
+ \langle \nabla x k(G_{\theta}(z), \cdot), \left[ J_{\theta+\epsilon v} G_{\theta+\epsilon v}(z)^\top - J_{\theta} G_{\theta}(z)^\top \right] v \rangle.
\]
It follows that
\[
\left\| \left( L_{\theta+\epsilon v}^\top - L_{\theta}^\top \right) v \right\|_{\mathcal{H}} \leq I_1 + I_2
\]
with
\[
I_1 \leq \left\| v \right\| \int \left\| \nabla x k(G_{\theta+\epsilon v}(z), \cdot) - \nabla x k(G_{\theta}(z), \cdot) \right\|_{\mathcal{H}} \left\| J_{\theta+\epsilon v} G_{\theta+\epsilon v}(z)^\top v \right\| v(dz)
\]
\[
\leq \sqrt{p} L \left\| v \right\| \int \left\| G_{\theta+\epsilon v}(z) - G_{\theta}(z) \right\| D(z) v(dz) \leq \sqrt{p} L \left\| v \right\|^2 \int D(z)^2 v(dz) =: C_3 \left\| v \right\|^2
\]
and
\[
I_2 \leq \left\| v \right\| \int \left\| \nabla x k(G_{\theta}(z), \cdot) \right\|_{\mathcal{H}} \left\| J_{\theta+\epsilon v} G_{\theta+\epsilon v}(z)^\top - J_{\theta} G_{\theta}(z)^\top \right\| v(dz)
\]
\[
\leq \sqrt{\alpha} L \left\| v \right\|^2 \int D(z) v(dz) =: C_4 \left\| v \right\|^2.
\]
Notice that we have used condition (12) to estimate $I_1$ and condition (13) to estimate $I_2$. By combining the above estimates, we obtain the desired result.

The second one is:

**Lemma 18.** Under the assumptions of Theorem 9, we have
\[
\mathcal{F}(q_{\theta_{\ell+1}}) - \mathcal{F}(q_{\theta_{\ell}}) \leq -\frac{1}{2} \epsilon \langle \mu_{p-q_{\theta_{\ell}}}, D_{\theta_{\ell}} f_{\ell} \rangle_{\mathcal{H}} \quad \text{for all } \ell \geq 1.
\]

**Proof.** Let $\ell \geq 1$ be arbitrary. For convenience, let us write $\theta := \theta_{\ell}$, $v := L_{\theta_{\ell}} f_{\ell}$, $\theta' := \theta_{\ell} + \epsilon_{\ell} v$, and $f := f_{\ell}$. Then by Lemma 7, we have
\[
\frac{d}{d\epsilon} \mathcal{F}(q_{\theta+\epsilon v}) = -\langle \mu_{p-q_{\theta+\epsilon v}}, L_{\theta+\epsilon v}^\top v \rangle_{\mathcal{H}} \quad \forall \epsilon \in [0, \epsilon_{\ell}].
\]
Therefore,
\[
\mathcal{F}(q_{\theta'}) - \mathcal{F}(q_{\theta}) = \int_{0}^{\epsilon_{\ell}} \frac{d}{d\epsilon} \mathcal{F}(q_{\theta+\epsilon v}) \, d\epsilon = -\int_{0}^{\epsilon_{\ell}} \langle \mu_{p-q_{\theta+\epsilon v}}, L_{\theta+\epsilon v}^\top v \rangle_{\mathcal{H}} \, d\epsilon
\]
\[
= -\epsilon_{\ell} \langle \mu_{p-q_{\theta_{\ell}}}, L_{\theta_{\ell}}^\top v \rangle_{\mathcal{H}} - \int_{0}^{\epsilon_{\ell}} \left[ \langle \mu_{p-q_{\theta_{\ell}+\epsilon v}}, L_{\theta_{\ell}+\epsilon v}^\top v \rangle_{\mathcal{H}} - \langle \mu_{p-q_{\theta_{\ell}}}, L_{\theta_{\ell}}^\top v \rangle_{\mathcal{H}} \right] \, d\epsilon.
\]
To estimate the integral term, observe that
\[
\left| \langle \mu_{p-q_{\theta_{\ell}+\epsilon v}}, L_{\theta_{\ell}+\epsilon v}^\top v \rangle_{\mathcal{H}} - \langle \mu_{p-q_{\theta_{\ell}}}, L_{\theta_{\ell}}^\top v \rangle_{\mathcal{H}} \right|
\]
\[
= \left| \langle \mu_{q_{\theta_{\ell}}-q_{\theta_{\ell}+\epsilon v}}, L_{\theta_{\ell}+\epsilon v}^\top v \rangle_{\mathcal{H}} + \langle \mu_{p-q_{\theta_{\ell}}}, (L_{\theta_{\ell}+\epsilon v}^\top - L_{\theta_{\ell}}^\top) v \rangle_{\mathcal{H}} \right|
\]
\[
\leq \left\| \mu_{q_{\theta_{\ell}}-q_{\theta_{\ell}+\epsilon v}} \right\|_{\mathcal{H}} \left\| L_{\theta_{\ell}+\epsilon v}^\top v \right\|_{\mathcal{H}} + \left\| \mu_{p-q_{\theta_{\ell}}} \right\|_{\mathcal{H}} \left\| (L_{\theta_{\ell}+\epsilon v}^\top - L_{\theta_{\ell}}^\top) v \right\|_{\mathcal{H}}.
\]
This together with Lemma 17 and the definition of $\mathcal{F}(q_\ell)$ gives

$$\left| \langle \mu_{p-q_\ell}, L_{\theta+\varepsilon_\ell} v \rangle_{\mathcal{H}} - \langle \mu_{p-q_\ell}, L_0 v \rangle_{\mathcal{H}} \right| \leq C \varepsilon \left( 1 + \sqrt{\mathcal{F}(q_\ell)} \right) \|v\|^2$$

with $C > 0$ depending only on the constants $C_1$, $C_2$, $C_3$, $C_4$ given in Lemma 17. Then by combining with (31) and $L_0 v = D_{\theta}\ell$ we arrive at

$$\mathcal{F}(q_{\ell+1}) - \mathcal{F}(q_\ell) \leq -\varepsilon_\ell \langle \mu_{p-q_\ell}, D_{\theta}f \rangle_{\mathcal{H}} + C_1^{-1} \varepsilon_\ell^2 \left( 1 + \sqrt{\mathcal{F}(q_\ell)} \right) \|\varepsilon\|^2.$$ 

Since $(\mu_{p-q_\ell}, D_{\theta}f)_{\mathcal{H}} = \langle (a D_\theta + \beta I) f, D_{\theta}f \rangle_{\mathcal{H}} = \|D_{\theta}f\|^2_{\mathcal{H}} + \beta \langle f, D_{\theta}f \rangle_{\mathcal{H}}$ and $\|\varepsilon\|^2 = \langle f, D_{\theta}f \rangle_{\mathcal{H}}$ by iii) of Proposition 3, we also have $\|\varepsilon\|^2 \leq \frac{1}{\beta} (\mu_{p-q_\ell}, D_{\theta}f)_{\mathcal{H}}$. Thus we infer further that

$$\mathcal{F}(q_{\ell+1}) - \mathcal{F}(q_\ell) \leq -\varepsilon_\ell \langle \mu_{p-q_\ell}, D_{\theta}f \rangle_{\mathcal{H}} \text{ for all } \ell \geq 1,$$

where we have returned to the original notation. We claim that (32) implies in particular that $\mathcal{F}(q_\ell) \leq \mathcal{F}(q_1)$ for all $\ell \geq 1$. Indeed, from (32) for $\ell = 1$ and condition (18) we get $\mathcal{F}(q_{\ell+1}) - \mathcal{F}(q_\ell) \leq 0$. Now if $\mathcal{F}(q_\ell) \leq \mathcal{F}(q_{\ell+1})$ for some $\ell \geq 1$, then again (32) and condition (18) give

$$\mathcal{F}(q_{\ell+1}) - \mathcal{F}(q_\ell) \leq -\varepsilon_\ell \langle \mu_{p-q_\ell}, D_{\theta}f \rangle_{\mathcal{H}} \leq 0.$$ 

Thus, $\mathcal{F}(q_{\ell+1}) \leq \mathcal{F}(q_\ell) \leq \mathcal{F}(q_1)$. Therefore, it follows by induction that the claim holds true. Owing to this claim and condition (18), we deduce from (32) that

$$\mathcal{F}(q_{\ell+1}) - \mathcal{F}(q_\ell) \leq -\varepsilon_\ell \langle \mu_{p-q_\ell}, D_{\theta}f \rangle_{\mathcal{H}} \leq \frac{1}{2} \varepsilon_\ell (\mu_{p-q_\ell}, D_{\theta}f)_{\mathcal{H}}$$

for every $\ell \geq 1$.

**Proof of Theorem 9.** In order to not to clutter notations we note hereafter $\alpha := \alpha_\ell$, and $\beta := \beta_\ell$. We have $\alpha \langle \mu_{p-q_\ell}, D_{\theta}f \rangle_{\mathcal{H}} = 2 \mathcal{F}(q_\ell) - 2 \beta \text{MMD}_{a,\beta}(p, q_\ell)^2$ from (29). Thus by combining with Lemma 18 we obtain

$$\frac{\mathcal{F}(q_{\ell+1}) - \mathcal{F}(q_\ell)}{\varepsilon_\ell} \leq -\alpha^{-1} \mathcal{F}(q_\ell) + \beta \alpha^{-1} \text{MMD}_{a,\beta}(p, q_\ell)^2 \quad \forall \ell \geq 1.$$ 

Let $\{\lambda_i, d_i\}_{i=0}^{\infty}$ be the eigensystem of $D_{\theta}$, the eigenvalues are given in decreasing order. Let $\lambda_i(\theta)$ be the smallest non zero eigenvalue.

$$2 \text{MMD}_{a,\beta}(p, q_\ell)^2 = \langle \mu_{p-q_\ell}, f_\ell \rangle_{\mathcal{H}} = \langle (a D_{\theta} + \beta I) f_\ell, f_\ell \rangle_{\mathcal{H}}$$

$$= \alpha \sum_{j=0}^i \lambda_j \langle f_\ell, d_j \rangle^2 + \beta \|f_\ell\|^2_{\mathcal{H}}$$

$$= \alpha \sum_{j=0}^i \lambda_j \langle f_\ell, d_j \rangle^2 + \beta \|f_\ell\|^2_{\mathcal{H}}$$

$$\geq \alpha \lambda_i(\theta_\ell) \|f_\ell\|^2_{\mathcal{H}} \left( 1 - \frac{\|P_{\text{Null}(D_{\theta})} f_\ell\|^2_{\mathcal{H}}}{\|f_\ell\|^2_{\mathcal{H}}} \right) + \beta \|f_\ell\|^2_{\mathcal{H}},$$

where the projection on the null space of $D_{\theta}$ is:

$$P_{\text{Null}(D_{\theta})} f_\ell = \sum_{j>i} \langle d_j, f_\ell \rangle d_j.$$
Let $a(\theta, f) = 1 - \frac{||p_{\text{Null}(D_i)} f||_\theta^2}{||f||_\theta^2}$. By our choice of $\theta_1$ and $\epsilon_{\ell-1}$, we have $f_\ell \notin \text{Null}(D_i)$, since we choose $\epsilon_{\ell-1}$ so that:

$$a(\theta_\ell, f_\ell) > \tau > 0$$

We conclude that:

$$\langle \mu_{p-q_\theta}, f_\ell \rangle \geq ||f_\ell||_\theta^2 \left( a\lambda_i(\theta_\ell) a(\theta_\ell, f_\ell) + \beta \right)$$

Using this we obtain

$$\langle \mu_{p-q_\theta}, f_\ell \rangle \leq ||\mu_{p-q_\theta}||_\theta ||f_\ell||_\theta \leq ||\mu_{p-q_\theta}||_\theta \sqrt{\frac{\langle \mu_{p-q_\theta}, f_\ell \rangle}{a\lambda_i(\theta_\ell) a(\theta_\ell, f_\ell) + \beta}}$$

yielding

$$\langle \mu_{p-q_\theta}, f_\ell \rangle \leq \frac{1}{a\lambda_i(\theta_\ell) a(\theta_\ell, f_\ell) + \beta} ||\mu_{p-q_\theta}||_\theta^2.$$ 

Hence it follows that:

$$\text{MMD}_{a, \beta}(p, q_\theta)^2 \leq \frac{\mathcal{F}(q_\theta)}{a\lambda_i(\theta_\ell) a(\theta_\ell, f_\ell) + \beta}.$$ 

Thus

$$\frac{\mathcal{F}(q_{\theta_{\ell+1}}) - \mathcal{F}(q_\theta)}{\epsilon_\ell} \leq -a^{-1} \left( 1 - \frac{\beta}{a\lambda_i(\theta_\ell) a(\theta_\ell, f_\ell) + \beta} \right) \mathcal{F}(q_\theta) = -\frac{\lambda_i(\theta_\ell) a(\theta_\ell, f_\ell)}{a\lambda_i(\theta_\ell) a(\theta_\ell, f_\ell) + \beta} \mathcal{F}(q_\theta)$$

which implies

$$\mathcal{F}(q_{\theta_{\ell+1}}) \leq \left[ 1 - \frac{\epsilon_\ell \lambda_i(\theta_\ell) a(\theta_\ell, f_\ell)}{a\lambda_i(\theta_\ell) a(\theta_\ell, f_\ell) + \beta} \right] \mathcal{F}(q_\theta)$$

for every $\ell = 1, 2, ...$ By iterating this estimate, we arrive at

$$\mathcal{F}(q_{\theta_{\ell+1}}) \leq \mathcal{F}(q_\theta) \prod_{j=1}^{\ell} \left[ 1 - \frac{\epsilon_j \lambda_i(\theta) a(\theta_j, f_j)}{a\lambda_i(\theta_j) a(\theta_j, f_j) + \beta_j} \right] \forall \ell \geq 1.$$ 

$$= \mathcal{F}(q_\theta) \prod_{j=1}^{\ell} \left[ 1 - \epsilon_j \chi_j \right]$$

$$\leq \mathcal{F}(q_\theta) \exp(-\sum_{j=1}^{\ell} \epsilon_j \chi_j).$$

In particular we have for for $\alpha \leq \frac{\tau}{2}$, and $\beta_i = \alpha_i \lambda_i(\theta_i)$, we have noting that for all $j$, we have: $\tau < a(\theta_j, f_j) \leq 1$:

$$\chi_j = \frac{\lambda_i(\theta_j) a(\theta_j, f_j)}{a\lambda_i(\theta_j) a(\theta_j, f_j) + \beta_j} \geq \frac{\lambda_i(\theta) \tau}{2\alpha_i \lambda_i(\theta)} = \frac{\tau}{2\alpha_i} \geq 1,$$

and hence we have:

$$\mathcal{F}(q_{\theta_{\ell+1}}) \leq \mathcal{F}(q_\theta) \exp(-\sum_{j=1}^{\ell} \epsilon_j \chi_j).$$
C \hspace{1em} \textbf{Parametric Kernelized Flows for a General Functional}

C.1 \hspace{1em} \textbf{Dynamic Formulation For MMD on a Statistical Manifold}

\textit{Proof of Theorem 10.} By using the dynamic of $\mu_{q_{\theta_0}}$ in \eqref{eq:1}, we have

$$\text{MMD}(q_{\theta_0}, q_{\theta_1}) = \|\mu_{q_{\theta_0}} - \mu_{q_{\theta_1}}\|_H = \left\| \int_0^1 \frac{d}{dt}\mu_{q_{\theta_t}} dt \right\|_H = \left\| \int_0^1 D_{\theta_t} f_t dt \right\|_H$$

which together with Jensen inequality yields

$$\text{MMD}^2(q_{\theta_0}, q_{\theta_1}) = \left(\int_0^1 D_{\theta_t} f_t dt\right)^2 \leq \int_0^1 \| D_{\theta_t} f_t \|_H^2 dt.$$ 

Thus it is enough to prove that there exists an admissible path $(\theta^*_t, f^*_t)$ satisfying

$$\text{MMD}^2(q_{\theta_0}, q_{\theta_1}) = \int_0^1 \| D_{\theta_t} f_t^* \|_H^2 dt. \hspace{1em} (33)$$

Let $(\theta^*_t, f^*_t)$ be the path given by assumption \eqref{eq:20}. In particular, we have

$$D_{\theta_t} f_t^* = 2\mu_{q_{\theta_t}^t - q_{\theta_t}^t}.$$ 

This together with a calculation in the proof of Theorem 6 gives

$$\frac{d}{dt} \text{MMD}^2(q_{\theta_t^t}, q_{\theta_t^t}) = -2 \left\langle \mu_{q_{\theta_t^t} - q_{\theta_t^t}}, D_{\theta_t} f_t^* \right\rangle_H = - \left\| D_{\theta_t} f_t^* \right\|_H^2.$$ 

It follows that this path satisfies optimal property \eqref{eq:33} since

$$\text{MMD}^2(q_{\theta_0}, q_{\theta_1}) = \int_0^1 \frac{d}{dt} \text{MMD}^2(q_{\theta_t^t}, q_{\theta_t^t}) dt = \int_0^1 \left\| D_{\theta_t} f_t^* \right\|_H^2 dt.$$ 

\hfill \Box

C.2 \hspace{1em} \textbf{Regularized MMD and gradient flows on a Statistical Manifold}

\textit{Proof of Theorem 12.} Let $t \mapsto \theta_t \in \Theta$ be a differentiable curve passing through $\theta$ at $t = 0$ and with tangent vector

$$\partial_t \theta_t \big|_{t=0} = \xi = L_{\theta} \varphi \text{ for } \varphi \in H. \hspace{1em} (34)$$

Then by using the chain rule we obtain

$$\left. \frac{dF(q_{\theta_t})}{dt} \right|_{t=0} = \left. \left\langle \nabla_{\theta_t} [F(q_{\theta_t})], \frac{d\theta_t}{dt} \right\rangle_{H} \right|_{t=0} = \left. \left\langle h_{\theta_t}, \nabla_{\theta_t} [\mu_{q_{\theta_t}}] \right\rangle_H, \frac{d\theta_t}{dt} \right|_{t=0} = \left. \left\langle h_{\theta_t}, \frac{d}{dt} \nabla_{\theta_t} [\mu_{q_{\theta_t}}] \right\rangle_H \right|_{t=0}.$$ 

Hence it follows from \eqref{eq:34}, \eqref{eq:1}, and \eqref{eq:23} that

$$\left. \frac{dF(q_{\theta_t})}{dt} \right|_{t=0} = \left\langle h_{\theta_t}, D_{\theta t} \varphi \right\rangle_H = \left\langle (aD_{\theta} + \beta I)u, D_{\theta} \varphi \right\rangle = g_{\theta} (L_{\theta} u, \xi)_{H}.$$ 

Therefore, we conclude from definition \eqref{eq:21} that $\text{grad} F(q_{\theta}) = L_{\theta} u.$ \hfill \Box
Gradient flows of Generic Functionals on the Statistical Manifold. Our framework is not limited to the MMD functional. In the following corollary we exhibit additional examples of functional $\mathcal{F}(q_\theta)$ defined on the statistical manifold along with their gradient flows w.r.t. $d_{a,b}$.

**Corollary 19.** For the (potential) energy functional $\mathcal{F}_1(q_\theta) = \int V(x)q_\theta(dx)$ with $V \in \mathcal{H}$, we have \[ \nabla_{d_{a,b}} \mathcal{F}_1(q_\theta) = L_\theta u, \text{ where } (\alpha D_\theta + \beta I)u = V. \]

• For the (entropy) functional $\mathcal{F}_1(q_\theta) = \int f(q_\theta(x))dx$ with $f: \mathbb{R} \to \mathbb{R}$ being continuously differentiable, we have $\nabla_{d_{a,b}} \mathcal{F}_1(q_\theta) = L_\theta u$, where $(\alpha D_\theta + \beta I)u = \int f'(q_\theta(x))k(x,\cdot)dx$.

• For the (interaction) functional $\mathcal{F}_3(q_\theta) = \int f(x)g(y)q_\theta(dx)q_\theta(dy)$ with $f, g \in \mathcal{H}$, we have $\nabla_{d_{a,b}} \mathcal{F}_3(q_\theta) = L_\theta u$, where $(\alpha D_\theta + \beta I)u = \left\langle f, \mu_{q_\theta}(x) \right\rangle \mathcal{H} + \left\langle g, \mu_{q_\theta} \right\rangle \mathcal{H} f$.

**Proof of Corollary 19.** This is a consequence of Theorem 12 observing that $\partial_{\theta_i} [\mathcal{F}_1(q_\theta)] = \left\langle V, \partial_{\theta_i} [\mu_{q_\theta}] \right\rangle \mathcal{H}$ since $\mathcal{F}_1(q_\theta) = \left\langle V, \mu_{q_\theta} \right\rangle \mathcal{H}$ and $\partial_{\theta_i} \mathcal{F}_2(q_\theta) = \left\langle f, \mu_{q_\theta}(x)k(x,\cdot)dx, \partial_{\theta_i} \mu_{q_\theta} \right\rangle \mathcal{H} \text{ since } \mathcal{F}_2(q_\theta) = \int f \left( \left\langle \mu_{q_\theta}, k(x,\cdot) \right\rangle \mathcal{H} \right) dx$. Note also that as $\mathcal{F}_3(q_\theta) = \left\langle f, \mu_{q_\theta} \right\rangle \mathcal{H} + \left\langle g, \mu_{q_\theta} \right\rangle \mathcal{H} f$, we have $\partial_{\theta_i} \mathcal{F}_3(q_\theta) = \left\langle f, \mu_{q_\theta} \right\rangle \mathcal{H} + \left\langle g, \mu_{q_\theta} \right\rangle \mathcal{H} f, \partial_{\theta_i} [\mu_{q_\theta}] \rangle \mathcal{H}$.

**Proof of Proposition 13.** This general fact can be seen from the proof of Theorem 12. Indeed,

\[
\frac{d}{dt} \mathcal{F}(q_{\theta_t}) = g_{\theta_t} \left( \nabla_{d_{a,b}} \mathcal{F}(q_{\theta_t}), \partial_{\theta_t} \right) = -g_{\theta_t} \left( L_{\theta_t} u_t, L_{\theta_t} u_t \right) = -\left\langle (\alpha D_{\theta_t} + \beta I)u_t, D_{\theta_t} u_t \right\rangle \mathcal{H} = -\left\langle h_{\theta_t}, D_{\theta_t} u_t \right\rangle \mathcal{H}.
\]

On the other hand, we obtain from equation (25) for $u_t$ that

\[
\alpha \left\langle h_{\theta_t}, D_{\theta_t} u_t \right\rangle \mathcal{H} + \beta \left\langle h_{\theta_t}, u_t \right\rangle \mathcal{H} = \|h_{\theta_t}\|^2 \mathcal{H}
\]

which gives

\[
\left\langle h_{\theta_t}, D_{\theta_t} u_t \right\rangle \mathcal{H} = \frac{1}{\alpha} \left[ \|h_{\theta_t}\|^2 \mathcal{H} - \beta \left\langle h_{\theta_t}, u_t \right\rangle \mathcal{H} \right] = \frac{1}{\alpha} \left[ \|h_{\theta_t}\|^2 \mathcal{H} - \beta \left\langle h_{\theta_t}, (\alpha D_{\theta_t} + \beta I)^{-1} h_{\theta_t} \right\rangle \mathcal{H} \right].
\]

Therefore, we deduce the first conclusion of the proposition. From (35), we also see that $\frac{d}{dt} \mathcal{F}(q_{\theta_t}) = 0$ if and only if $\alpha \|D_{\theta_t} u_t\|^2 \mathcal{H} + \beta \left\langle u_t, D_{\theta_t} u_t \right\rangle \mathcal{H} = 0$. That is, $\frac{d}{dt} \mathcal{F}(q_{\theta_t}) = 0$ if and only if $D_{\theta_t} u_t = 0$. But by exactly the same reason as in the proof of Corollary 5, we have $D_{\theta_t} u_t = 0$ is equivalent to $D_{\theta_t} h_{\theta_t} = 0$. Thus the last conclusion of the proposition follows.

**D Convergence of Flows**

**Proof of Proposition 16.** From Proposition 13, we have

\[
\frac{d}{dt} \mathcal{F}(q_{\theta_t}) = -\frac{1}{\alpha} \left[ \|h_{\theta_t}\|^2 \mathcal{H} - \beta \left\langle h_{\theta_t}, u_t \right\rangle \mathcal{H} \right].
\]
By the proof of Theorem 9 we have:

$$\langle h_\theta, u_i \rangle_\mathcal{H} \leq \frac{1}{\alpha \lambda_i(\theta_1) a(\theta_1, u_i) + \beta} \| h_\theta \|^2_\mathcal{H}.$$ 

This together with (36) and assumption (26) gives

$$\frac{d}{dt} \mathcal{F}(q_{\theta_i}) \leq -\frac{1}{\alpha} \left(1 - \frac{\beta}{\alpha \lambda_i(\theta_1) a(\theta_1, u_i) + \beta} \right) \| h_\theta \|^2_\mathcal{H} \leq -\frac{\lambda_i(\theta_1) a(\theta_1, u_i) \gamma(\theta_i)}{\alpha \lambda_i(\theta_1) a(\theta_1, u_i) + \beta} \mathcal{F}(q_{\theta_i}).$$

It follows that

$$\log \left( \frac{\mathcal{F}(q_{\theta_i})}{\mathcal{F}(q_{\theta_j})} \right) = \int_0^t \frac{d}{ds} \left[ \log(\mathcal{F}(q_{\theta_i})) \right] ds \leq - \int_0^t \frac{\lambda_i(\theta_s) a(\theta_s, u_s) \gamma(\theta_s)}{\alpha \lambda_i(\theta_s) a(\theta_s, u_s) + \beta} ds,$$

This gives decay estimate (27). \qed

E Algorithm

**Algorithm 1** MMD GAN with Discrete Parametric Kernelized Flows w.r.t. $d_{\alpha, \beta}$

**Input:** $\alpha > 0$ gradient penalty weight, $\eta$ Learning rate, $n_c$ number of iterations for training the critic, N batch size

**Initialize** witness function $f(x) = \langle v, \Phi(x) \rangle$, Generator $G_\theta$, initialize $v, \theta, \Phi$. Note by $p$ parameters of $v, \Phi$.

**repeat**

[Update of the witness function of MMD$_{\alpha, \beta}(p, G_{\theta,#}\nu)$ ]

**for** $j = 1$ to $n_c$ **do**

- Sample a minibatch $x_i, i = 1 \ldots N, x_i \sim p$
- Sample a minibatch $z_i, i = 1 \ldots N, z_i \sim \nu$
- Compute $\text{MMD}_{\alpha, \beta}(p, G_{\theta,#}(\nu)) = -M(p, \theta)$

$$M(p, \theta) = \frac{1}{N} \sum_{i=1}^N f(G(\theta)(z_i)) - \frac{1}{N} \sum_{i=1}^N f(x_i) + \alpha \left\| \nabla_\theta \frac{1}{N} \sum_{i=1}^N f(G_\theta(z_i)) \right\|^2$$

[We omit the $\beta$ regularizer since SGD achieves similar effet]

[A better estimate of $\| \nabla_\theta \mathbb{E}_x f(G_\theta(z)) \|^2$ can be obtained by using $N^2$ independent samples or by using a variance estimate, but we found this estimate to be enough in practice ]

**if** Fixed Kernel **then**

$$v \leftarrow v - \eta \text{RmsProp}(\nabla_v M(p, \theta))$$

**else if** Learned Kernel **then**

$$p \leftarrow p - \eta \text{RmsProp}(\nabla_p M(p, \theta))$$

**end if**

**end for**

[Generator update: Parametric Discrete Kernel Flow w.r.t. $d_{\alpha, \beta}$ on the statistical Manifold ]

- Sample $z_i, i = 1 \ldots N, z_i \sim \nu$
- $d_{\theta} \leftarrow -\nabla_\theta \frac{1}{N} \sum_{i=1}^N f(G_\theta(z_i))$
- $\theta \leftarrow \theta - \eta \text{RmsProp}(d_{\theta})$

**until** $\theta$ converges

F Additional Experiments and Plots

F.1 MMD GAN when the witness function is a multilayer Neural Network: i.e. Learned Kernel
Figure 2: Trajectories of Kernelized Gradient flows of the MMD functional for $\alpha = 0$ (no gradient regularization) and $\alpha = 100$. It is clear that the Riemannian structure induced by $d_{a,\beta}$, $\alpha > 0$ guarantees the convergence, while we suffer from cycles and mode collapse for $\alpha = 0$. When the kernel is learned, i.e. the witness function is a multilayer neural network, the gradient flow exhibits qualitatively similar behavior to the fixed kernel one (compare Fig 1c of the fixed kernel to Fig 2e of the learned kernel). This suggests possibly a Neural Tangent Kernel Regime that needs further analysis.
