Abstract. We study the existence of solutions for Darcy’s problem coupled with the heat equation under singular forcing; the right-hand side of the heat equation corresponds to a Dirac measure. The studied model allows thermal diffusion and viscosity depending on the temperature. We propose a finite element solution technique and analyze its convergence properties. In the case that the thermal diffusion is constant, we propose an a posteriori error estimator and investigate reliability and efficiency properties. We illustrate the theory with numerical examples.

Key words. nonlinear Darcy’s equations, singular heat equation, Dirac measures, finite element approximation, a posteriori error estimates.

1. Introduction. In this work we are interested in the analysis and discretization of the temperature distribution of a fluid in a porous medium modelled by a convection–diffusion equation coupled with Darcy’s law. To make matters precise, we let Ω ⊂ R^2 be an open and bounded domain with Lipschitz boundary ∂Ω. We are interested in the analysis and discretization of the following system of partial differential equations (PDEs) in its strong form:

\[
\begin{align*}
\nu(T)u + \nabla p &= f \quad \text{in } \Omega, \\
\text{div } u &= 0 \quad \text{in } \Omega, \\
-\text{div}(\kappa(T)\nabla T) + \text{div}(uT) &= g \quad \text{in } \Omega, \\
u \cdot n &= 0 \quad \text{on } \partial\Omega, \\
T &= 0 \quad \text{on } \partial\Omega.
\end{align*}
\]

The unknowns are the velocity field \(u\), the pressure \(p\), and the temperature \(T\) of the fluid, respectively. The data are the viscosity coefficient \(\nu\), the thermal diffusivity coefficient \(\kappa\), the external density force \(f\), and the external heat source \(g\). The viscosity and thermal diffusivity coefficients may depend nonlinearly on the temperature \(T\). In (1), \(n\) denotes the unit outward normal vector on \(\partial\Omega\). In this work we are particularly interested in the case that \(g = \delta_z\), where \(\delta_z\) corresponds to the Dirac delta distribution supported at the interior point \(z \in \Omega\).

The analysis and discretization of the heat equation coupled with Darcy’s law by a nonlinear viscosity depending on the temperature have been studied in a number of works. To the best of our knowledge, the first article that considers such a problem is [16]. In this work the authors derive existence of solutions, without restriction on...
the data, by Galerkin’s method and Brower’s fixed point theorem [16, Theorem 2.3]; uniqueness is established when the data are suitably restricted [16, Theorem 2.6]. In addition, the authors of [16] propose and analyze two numerical schemes based on finite element methods and derive optimal a priori error estimates. Recently, the results of [16] have been complemented and extended in [30], where the authors introduce a new non-stabilized method and prove, for a sufficiently small mesh-size, existence and uniqueness of a solution; a priori error estimates are also derived. Later, in [31], the authors devise and analyze a posteriori error estimators for the two numerical schemes considered in [16]. In the recent work [34], the authors analyze a new fully-mixed finite element method based on the introduction of the pseudoheat flux as a further unknown. The authors prove the unique solvability of the underlying continuous formulation, present a discrete formulation, and derive a priori error estimates. We conclude this paragraph by mentioning the work [17], where a different coupling of Darcy’s system with the heat equation is analyzed: the viscosity \( \nu \) is constant but the exterior force \( f \) depends on the temperature. In this work, the authors provide existence and uniqueness results and analyze a spectral discretization.

When, in system (1), with smooth forcing, the Darcy’s system is replaced by the stationary Navier–Stokes equations, we arrive at the classical and generalized steady state Boussinesq problems [37, 41]. These problems, which are particular instances of an incompressible nonisothermal fluid flow model, have been extensively studied over the last decades; it is thus no surprise that their analysis and approximation, at least in energy-type spaces, are very well developed. For a variety of finite element solution techniques used to discretize the classical and generalized steady state Boussinesq problems, we refer the interested reader to the following nonexhaustive list of references: [19, 18, 33, 4, 24, 29, 38, 27, 9, 5, 6, 7, 8]; see also the references therein. To conclude this paragraph, we mention the work [7], where the authors study, on the basis of weighted estimates and weighted Sobolev spaces, existence and approximation results for a Boussinesq model of thermally driven convection under singular forcing; a posteriori error estimates are also analyzed.

To best of our knowledge, this is the first work that analyzes problem (1) with singular data. Our main source of difficulty and interest here is that the external heat source is rough or singular. As a result standard energy arguments do not apply; the fluid velocity and the temperature lie in different spaces. In addition, the temperature \( T \) exhibits reduced regularity properties: \( T \in W^{1,p}_0(\Omega) \setminus H_0^1(\Omega) \), with \( p < 2 \). This and the fact that the velocity component of a solution to the Darcy’s problem has very low regularity, namely, \( u \in H_0^1(\div, \Omega) \), complicate both the analysis of the continuous problem and the study of discretization techniques. Regarding discretization, we devise suitable adaptive finite element methods (AFEMs) to solve (1). These techniques are motivated by the fact that \( T \) exhibits reduced regularity properties. In what follows we list what, we believe, are the main contributions of our work:

- **Existence of solutions**: We introduce a concept of weak solution within the space \( \mathbf{H}_0(\div, \Omega) \times L^2(\Omega) \times W^{1,p}_0(\Omega) \), with \( p < 2 \), and show, on the basis of a fixed point argument, the existence of solutions; see Theorem 6.

- **Discretization**: We discretize the coupled system (1) by using the Raviart–Thomas finite element space of order zero, piecewise constant finite elements, and continuous piecewise linear finite elements for the velocity, the pressure, and the temperature, respectively. Under suitable assumptions on data we prove, in Theorem 10, the existence of discrete solutions and, in Theorem 11, the existence of a subsequence that weakly converges to a solution of the continuous problem.
• A posteriori error estimates: We devise a residual–based a posteriori error estimator for the proposed finite element discretization of system (1) that can be decomposed as the sum of three individual contributions: one contribution that accounts for the discretization of the heat equation and two contributions related to the discretization of the Darcy’s system. We prove, in Theorem 13, that the devised error estimator is globally reliable. We explore local efficiency estimates in Section 5.3.

The rest of the manuscript is organized as follows. We set notation and collect background information in Section 2. In Section 3, we introduce a notion of weak solution for problem (1) and analyze the existence of solutions. A numerical discretization technique for problem (1) is proposed in Section 4, where we also analyze convergence properties of discretizations. In Section 5, we design and analyze an a posteriori error estimator for the proposed finite element scheme. We derive global reliability properties and explore local efficiency estimates. Finally, a series of numerical experiments are presented in Section 6, which illustrate the theory and reveal a competitive performance of AFEMs based on the devised a posteriori error estimator.

2. Notation and preliminaries. Let us set notation and describe the setting we shall operate with.

2.1. Notation. Let $d \in \{1, 2\}$ and $\mathcal{O} \subset \mathbb{R}^d$ be an open and bounded domain. We shall use standard notation for Lebesgue and Sobolev spaces. The space of functions in $L^2(\mathcal{O})$ that have zero average is denoted by $L^2_0(\mathcal{O})$. By $W^{m,r}(\mathcal{O})$, we denote the Sobolev space of functions in $L^r(\mathcal{O})$ with partial derivatives of order up to $m$ in $L^r(\mathcal{O})$; $m$ denotes a positive integer and $1 \leq r \leq \infty$. We denote by $W^{m,r}_0(\mathcal{O})$ the closure with respect to the norm in $W^{m,r}(\mathcal{O})$ of the space of $C^\infty$ functions compactly supported in $\mathcal{O}$. We use uppercase bold letters to denote the vector-valued counterparts of the aforementioned spaces whereas lowercase bold letters are used to denote vector-valued functions.

Let us introduce some spaces utilized in the analysis of Darcy’s problem:

$$
\mathbf{H}(\text{div}, \mathcal{O}) := \{ \mathbf{v} \in L^2(\mathcal{O}) : \text{div} \mathbf{v} \in L^2(\mathcal{O}) \}
$$

and $\mathbf{H}_0(\text{div}, \mathcal{O}) := \{ \mathbf{v} \in \mathbf{H}(\text{div}, \mathcal{O}) : \mathbf{v} \cdot \mathbf{n}|_{\partial \mathcal{O}} = 0 \}$. We equip both spaces, $\mathbf{H}(\text{div}, \mathcal{O})$ and $\mathbf{H}_0(\text{div}, \mathcal{O})$, with the following norm:

$$
\|\mathbf{v}\|_{\mathbf{H}(\text{div}, \mathcal{O})} := \left( \|\mathbf{v}\|_{L^2(\mathcal{O})}^2 + \|\text{div} \mathbf{v}\|_{L^2(\mathcal{O})}^2 \right)^{\frac{1}{2}}.
$$

We also introduce $\mathbf{V}(\mathcal{O}) := \{ \mathbf{v} \in \mathbf{H}_0(\text{div}, \mathcal{O}) : \text{div} \mathbf{v} = 0 \}$.

To perform an a posteriori error analysis, we will make use of the so-called curl operator. When $d = 2$, we define, for $\mathbf{v} \in H^1(\mathcal{O})$ and $\mathbf{v} = (v_1, v_2) \in \mathbf{H}^1(\mathcal{O})$,

$$
\text{curl} \mathbf{v} := \left( \frac{\partial v_2}{\partial x_1}, -\frac{\partial v_1}{\partial x_2} \right), \quad \text{curl} \mathbf{v} := \frac{\partial v_2}{\partial x_1} - \frac{\partial v_1}{\partial x_2}.
$$

With this operator at hand, we define $\mathbf{H}(\text{curl}, \Omega) := \{ \mathbf{v} \in L^2(\Omega)^2 : \text{curl} \mathbf{v} \in L^2(\Omega) \}$.

If $\mathcal{W}$ and $\mathcal{Z}$ are Banach function spaces, we write $\mathcal{W} \hookrightarrow \mathcal{Z}$ to denote that $\mathcal{W}$ is continuously embedded in $\mathcal{Z}$. We denote by $\mathcal{W}'$ and $\| \cdot \|_{\mathcal{W}}$ the dual and the norm of $\mathcal{W}$, respectively. Given $p \in (1, \infty)$, we denote by $p'$ its Hölder conjugate, i.e., the real number such that $1/p + 1/p' = 1$. The relation $a \lesssim b$ indicates that $a \leq Cb$, with a constant $C$ that neither depends on $a$, $b$, nor the discretization parameters. The value of $C$ might change at each occurrence.
We finally mention that, throughout this work $\Omega \subset \mathbb{R}^2$ is an open and bounded polygonal domain with Lipschitz boundary $\partial \Omega$.

### 2.2. Darcy’s equations.

We begin this section by recalling the fact that, on Lipschitz domains, the divergence operator is surjective from $H_0(\text{div}, \Omega)$ to $L^2_0(\Omega)$: there exists $\beta > 0$ such that [16, inequality (2.14)], [31, inequality (2.13)]

\[
\inf_{q \in L^2_0(\Omega)} \sup_{v \in H_0(\text{div}, \Omega)} \frac{\int_{\Omega} q \, \text{div} \, v \, dx}{\|v\|_{H_0(\text{div}, \Omega)} \|q\|_{L^2(\Omega)}} \geq \beta > 0.
\]

We introduce the following weak formulation of standard Darcy’s equations: Find $(u, p) \in H_0(\text{div}, \Omega) \times L^2_0(\Omega)$ such that

\[
\begin{align*}
\int_{\Omega} (\eta u \cdot v - p \, \text{div} \, v) \, dx &= \int_{\Omega} f \cdot v \, dx \quad \forall v \in H_0(\text{div}, \Omega), \\
\int_{\Omega} q \, \text{div} \, u \, dx &= 0 \quad \forall q \in L^2_0(\Omega).
\end{align*}
\]

Here, $f \in L^2(\Omega)$ and $\eta$ denotes a function in $L^\infty(\Omega)$ that satisfies

\[
\eta_- \leq \eta(x) \leq \eta_+ \quad \text{for a.e.} \quad x \in \Omega, \quad \eta_-, \eta_+ > 0.
\]

The next result follows from the inf-sup theory for saddle point problems [32, Theorem 2.34].

**Theorem 1 (well-posedness of Darcy’s equations).** Let $f \in L^2(\Omega)$ and $\eta \in L^\infty(\Omega)$ be such that (4) holds. Then, problem (3) admits a unique solution $(u, p) \in H_0(\text{div}, \Omega) \times L^2_0(\Omega)$. In addition, the following estimate holds:

\[
\|u\|_{H_0(\text{div}, \Omega)} + \|p\|_{L^2(\Omega)} \lesssim \|f\|_{L^2(\Omega)},
\]

where the hidden constant is independent of the data $f$, $\eta$ and the solution $(u, p)$.

### 3. The coupled problem.

The main goal of this section is to show the existence of weak solutions for problem (1). As a first step, we introduce the set of assumptions under which we will operate and set a weak formulation.

#### 3.1. Main assumptions and weak formulation.

We will operate under the following assumptions on the viscosity and diffusivity coefficients.

- **Viscosity**: The viscosity $\nu$ is a function that is strictly positive and bounded, i.e., there exist positive constants $\nu_-$ and $\nu_+$ such that

\[
\nu_- \leq \nu(s) \leq \nu_+ \quad \forall s \in \mathbb{R}.
\]

In addition, we assume that $\nu \in C^{0.1}(\mathbb{R})$ with Lipschitz constant $C_L$, i.e.,

\[
|\nu(s_1) - \nu(s_2)| \leq C_L |s_1 - s_2| \quad \forall s_1, s_2 \in \mathbb{R}.
\]

- **Diffusivity**: The thermal coefficient $\kappa$ is a strictly positive and bounded function, i.e., there exist positive constants $\kappa_-$ and $\kappa_+$ such that

\[
\kappa_- \leq \kappa(s) \leq \kappa_+ \quad \forall s \in \mathbb{R}.
\]

We also assume that $\kappa \in C^{0.1}(\mathbb{R})$. 

3.2. Weak solutions. We adopt the following notion of weak solution.

**Definition 2** (weak solution). Let \( f \in \mathbf{L}^2(\Omega) \), \( z \in \Omega \), and \( p < 2 \). We say that \((u, p, T) \in \mathbf{H}_0(\text{div}, \Omega) \times L_0^2(\Omega) \times W_0^{1,p}(\Omega)\) is a weak solution to (1) if

\[
\begin{align*}
\int_{\Omega} (\nu(T) u \cdot v - p \text{ div } v) \, dx &= \int_{\Omega} f \cdot v \, dx \quad \forall v \in \mathbf{H}_0(\text{div}, \Omega), \\
\int_{\Omega} q \text{ div } u \, dx &= 0 \quad \forall q \in L_0^2(\Omega), \\
\int_{\Omega} (\kappa(T) \nabla T \cdot \nabla S - T u \cdot \nabla S) \, dx &= \langle \delta_z, S \rangle \quad \forall S \in W_0^{1,p}(\Omega).
\end{align*}
\]

Here, \( \langle \cdot, \cdot \rangle \) denotes the duality pairing between \( W_0^{1,p}(\Omega) \) and \( W^{-1,p}(\Omega) := (W_0^{1,p}(\Omega))^\prime \).

The following comments are now in order. The asymptotic behavior of solutions \( \chi \) to second order elliptic problems with homogeneous Dirichlet boundary conditions and \( \delta_z \) as a forcing term is dictated by \( |\nabla \chi(x)| \approx |x - z|^{-1} \) [36, Theorem 3.3]. On the basis of a simple computation, this asymptotic behavior motivates us to seek for a temperature distribution within the space \( W_0^{1,p}(\Omega) \) for \( p < 2 \). On the other hand, we notice that, owing to our assumptions on data and definition of weak solution, all terms in problem (7) are well-defined. In particular, in view of Hölder’s inequality, we have the following bound for the convective term:

\[
\left| \int_{\Omega} T u \cdot \nabla S \, dx \right| \leq \|u\|_{L^2(\Omega)} \|T\|_{L^{2,p}(\Omega)} \|\nabla S\|_{L^p(\Omega)} \leq C_\varepsilon \|u\|_{L^p(\Omega)} \|\nabla T\|_{L^{p}(\Omega)} \|\nabla S\|_{L^{p}(\Omega)},
\]

where we have utilized the standard Sobolev embedding \( W_0^{1,p}(\Omega) \hookrightarrow L^{2,p}(\Omega) \) [1, Theorem 4.12, Case C]; \( C_\varepsilon \) denotes the best constant in such an embedding.

3.3. A problem for the single variable \( T \). To analyze problem (7), we follow the ideas in [16, Section 2.2] and observe that (7) can be rewritten as a problem for the single variable \( T \). In fact, for a given temperature \( T \), the first two equations in problem (7) correspond to a Darcy’s problem that, in view of Theorem 1, admits a unique solution \((u, p) \in \mathbf{H}_0(\text{div}, \Omega) \times L_0^2(\Omega)\). We notice that the variables \( u \) and \( p \) can be seen as functions depending on \( T \). This motivates the notation \((u, p) = (u(T), p(T))\).

Problem (7) is thus equivalent to the following reduced formulation [16, Section 2.2]: Find \( T \in W_0^{1,p}(\Omega) \), with \( p < 2 \), such that

\[
\int_{\Omega} (\kappa(T) \nabla T \cdot \nabla S - T u(T) \cdot \nabla S) \, dx = \langle \delta_z, S \rangle \quad \forall S \in W_0^{1,p}(\Omega),
\]

where \( u(T) \in \mathbf{H}_0(\text{div}, \Omega) \) denotes the velocity component of the solution \((u(T), p(T))\) to the following problem: Find \((u(T), p(T)) \in \mathbf{H}_0(\text{div}, \Omega) \times L_0^2(\Omega)\) such that

\[
\begin{align*}
\int_{\Omega} (\nu(T) u(T) \cdot v - p(T) \text{ div } v) \, dx &= \int_{\Omega} f \cdot v \, dx \quad \forall v \in \mathbf{H}_0(\text{div}, \Omega), \\
\int_{\Omega} q \text{ div } u(T) \, dx &= 0 \quad \forall q \in L_0^2(\Omega).
\end{align*}
\]

3.4. A stationary heat equation with convection. In this section, we study the existence and uniqueness of solutions for a stationary heat equation with convection and singular forcing. To accomplish this task, we begin our studies by introducing the function \( \xi \in L^\infty(\Omega) \), which is such that

\[
\xi_- \leq \xi(x) \leq \xi_+ \quad \text{for a.e. } x \in \Omega, \quad \xi_-, \xi_+ > 0.
\]
In addition, we assume that $\xi$ is uniformly continuous. With this function at hand, we introduce the following weak version of the aforementioned stationary heat equation with convection:

\[(12) \quad T \in \dot W_0^{1,p} (\Omega) : \int_{\Omega} (\xi \nabla T \cdot \nabla S - T \nabla \cdot \nabla S) \, dx = \langle \delta_z, S \rangle \quad \forall S \in \dot W_0^{1,p} (\Omega).\]

Here, $p$ is such that $4/3 - \epsilon < p < 2$, where $\epsilon > 0$, $v \in L^2 (\Omega)$, $z \in \Omega$, and $1/p + 1/p' = 1$.

We present the following well-posedness result.

**Proposition 3** (case $v = 0$). Let $\xi \in L^\infty (\Omega)$ be such that (11) holds. Assume, in addition, that $\xi$ is uniformly continuous. Then, problem (12) with $v = 0$ is well-posed. This, in particular, implies that

\[(13) \quad \| \nabla R \|_{L^p (\Omega)} \leq C_\xi \sup_{S \in \dot W_0^{1,p'} (\Omega)} \frac{\int_{\Omega} \xi \nabla R \cdot \nabla S \, dx}{\| \nabla S \|_{L^{p'} (\Omega)}} \quad \forall R \in \dot W_0^{1,p} (\Omega),\]

with a constant $C_\xi$ depending on $\xi$, $p$, and $\Omega$.

**Proof.** The well-posedness of problem (12) on Lipschitz domains with $v = 0$ for $p$ such that $4/3 - \epsilon < p < 2$ and $\epsilon > 0$ follows, for instance, from [40, Theorem B]. Notice that $\xi$ is bounded and uniformly continuous. With such a result at hand, the inf-sup condition (13) thus follows from [32, Theorem 2.6]. \(\square\)

We now analyze the case with nonzero convection.

**Proposition 4** (case $v \neq 0$). Let $\xi \in L^\infty (\Omega)$ be such that (11) holds. Assume, in addition, that $\xi$ is uniformly continuous. If

\[(14) \quad C_\xi C_e \| v \|_{L^2 (\Omega)} \leq \alpha < 1,\]

with $C_e$ being the best constant in the Sobolev embedding $W_0^{1,p} (\Omega) \hookrightarrow L^{2,p} (\Omega)$, then problem (12) is well-posed. This, in particular, implies that the solution $T \in \dot W_0^{1,p} (\Omega)$ of problem (12) satisfies

\[(15) \quad \| \nabla T \|_{L^p (\Omega)} \leq C_\alpha \| \delta_z \|_{W^{-1,p} (\Omega)}, \quad C_\alpha = \frac{C_\xi}{1 - \alpha}, \quad 4/3 - \epsilon < p < 2.\]

**Proof.** We begin the proof by introducing the map $A : \dot W_0^{1,p} (\Omega) \to W^{-1,p} (\Omega)$ by

\[\langle AT, S \rangle := \int_{\Omega} \xi \nabla T \cdot \nabla S \, dx, \quad \forall T \in \dot W_0^{1,p} (\Omega), \forall S \in W_0^{1,p'} (\Omega).\]

It is clear that $A$ is linear and bounded. In addition, in view of the inf-sup condition (13), we conclude that $A$ is invertible and $\| A^{-1} \|_{L(W^{-1,p} (\Omega), W_0^{1,p} (\Omega))} \leq C_\xi$.

Let $v \in L^2 (\Omega)$. Let us also introduce the map $B_v : \dot W_0^{1,p} (\Omega) \to W^{-1,p} (\Omega)$ by

\[\langle B_v T, S \rangle := -\int_{\Omega} T v \cdot \nabla S \, dx, \quad \forall T \in \dot W_0^{1,p} (\Omega), \forall S \in W_0^{1,p'} (\Omega).\]

The map $B_v$ is linear and, in view of (8), bounded. In fact, we have

\[
|B_v|_{L(W_0^{1,p} (\Omega), W^{-1,p} (\Omega))} = \sup_{T \in \dot W_0^{1,p} (\Omega)} \frac{|B_v T|_{W^{-1,p} (\Omega)}}{|\nabla T|_{L^p (\Omega)}} \leq C_e \| v \|_{L^2 (\Omega)}. \]
We thus employ the previously defined linear and bounded maps $A$ and $B_{\nu}$ to rewrite problem (12) as the following operator equation in $W_0^{1,p}(\Omega)$: $(I + A^{-1}B_{\nu})T = A^{-1}\delta_z$. We now observe that the boundedness of the maps $A^{-1}$ and $B_{\nu}$ combined with assumption (14) yield that the $L(W_0^{1,p}(\Omega))$-norm of the map $A^{-1}B_{\nu}$ is bounded by $C_{\xi}C_{\nu}\|\nu\|_{L^2(\Omega)} \leq \alpha < 1$. This bound, in view of [44, Theorem 1,B], allows us to conclude that problem (12) admits a unique solution. The desired bound for $T$ can be obtained directly from the aforementioned operator equation. In fact, we have
\[
\|\nabla T\|_{L^p(\Omega)} \leq \frac{\|A^{-1}\|_{L(W^{-1,p}(\Omega),W_0^{1,p}(\Omega))}\|\delta_z\|_{W^{-1,p}(\Omega)}}{1 - \|A^{-1}B_{\nu}\|_{L(W_0^{1,p}(\Omega))}} \leq \frac{C_{\xi}}{1 - \alpha} \|\delta_z\|_{W^{-1,p}(\Omega)}.
\]
This concludes the proof.

3.5. The coupled problem. We now proceed to analyze the existence of solutions for problem (9)-(10) on the basis of a fixed point argument. Let $p < 2$ and let $F : W_0^{1,p}(\Omega) \to W_0^{1,p}(\Omega)$ be the map defined by $F(\theta) = \zeta$, where $\zeta$ denotes the solution to the following problem: Find $\zeta \in W_0^{1,p}(\Omega)$ such that
\[
\int_{\Omega} (\kappa(\theta)\nabla \zeta \cdot \nabla S - \zeta u(\theta) \cdot \nabla S)\,dx = \langle \delta_z, S \rangle \quad \forall S \in W_0^{1,p'}(\Omega).
\]
We recall that $1/p + 1/p' = 1$. Notice that the definition of $\zeta$ implies solving, for a prescribed temperature $\theta \in W_0^{1,p}(\Omega)$, a Darcy’s problem with viscosity $\nu(\theta)$. Since $\nu$ satisfies the estimates in (5), Theorem 1 guarantees the existence of a unique solution $(u(\theta), p(\theta))$ for such a problem. Once this solution is obtained, the stationary heat equation (16), with the nonzero convection $u(\theta)$, is thus solved to obtain $\zeta \in W_0^{1,p}(\Omega)$.

As a first instrumental result, we prove that the mapping $F$ is well-defined. To accomplish this task, we introduce the ball
\[
\mathcal{B}_T := \left\{ \theta \in W_0^{1,p}(\Omega) \, : \, \|\nabla \theta\|_{L^p(\Omega)} \leq C_{1/2} \|\delta_z\|_{W^{-1,p}(\Omega)} \right\},
\]
where $C_{1/2}$ is as in (15). Since it will be useful in the analysis that follows, we define
\[
\mathcal{C} := (2C_{e}C_{\kappa})^{-1},
\]
where $C_{e}$ is defined as in (8) and $C_{\kappa}$ corresponds to the constant involved in the inf-sup condition (13) when $\xi$ is replaced by $\kappa$.

Lemma 5 ($F$ is well-defined). Let $p$ such that $4/3 - \epsilon < p < 2$ and $\epsilon > 0$. Let $f$ be such that $\|f\|_{L^2(\Omega)} \leq \mathcal{C} \nu_\epsilon$, where $\nu_\epsilon$ is as in (5). Then, the map $F$ is well-defined on $\mathcal{B}_T$ and, in addition, $F(\mathcal{B}_T) \subset \mathcal{B}_T$.

Proof. Let $\theta \in \mathcal{B}_T$. Invoke Theorem 1 to conclude the existence of a unique pair $(u(\theta), p(\theta)) \in H_0(\text{div}, \Omega) \times L^p(\Omega)$ solving (10) with $T = \theta$. In addition, by testing $\mathbf{v} = u(\theta)$ in the first equation of (10), we immediately obtain the estimate
\[
\|u(\theta)\|_{L^2(\Omega)} \leq \nu_\epsilon^{-1} \|f\|_{L^2(\Omega)} \leq \mathcal{C} = (2C_{e}C_{\kappa})^{-1},
\]
upon utilizing definition (17). Consequently, $u(\theta)$ satisfies the bound (14) with $\alpha = \frac{1}{2}$. We are thus in position to apply the results of Proposition 4 to conclude the existence of a unique solution $\zeta \in W_0^{1,p}(\Omega)$ to (16) satisfying $\|\nabla \zeta\|_{L^p(\Omega)} \leq C_{1/2} \|\delta_z\|_{W^{-1,p}(\Omega)}$. We have thus proved that $\zeta \in \mathcal{B}_T$.  

\[\square\]
We now proceed to obtain an existence result for problem (9)–(10) via a fixed point argument.

**Theorem 6** (existence). Under the assumptions of Lemma 5, there exists a solution \((u, p, T) \in H_0(\text{div}, \Omega) \times L^2_0(\Omega) \times W^{1,p}_0(\Omega)\) for problem (7). In addition, we have that \(T \in \mathcal{B}_T\).

**Proof.** We proceed on the basis of the Leray–Schauder fixed point theorem for the map \(F : \mathcal{B}_T \to \mathcal{B}_T\) [28, Theorem 8.8], [44, Theorem 2.A]. In order to apply such a theorem, we first observe that, directly from its definition, the set \(\mathcal{B}_T\) is nonempty, closed, bounded, and convex. Additionally, Lemma 5 guarantees that \(F(\mathcal{B}_T) \subset \mathcal{B}_T\).

It thus suffices to prove that \(F\) is compact.

Let \(\{\theta_n\}_{n \geq 0} \subset \mathcal{B}_T\) be a sequence such that \(\theta_n \to \theta \in W^{1,p}_0(\Omega)\) for \(p < 2\). Since \(\mathcal{B}_T\) is closed and convex, it immediately follows that \(\mathcal{B}_T\) is weakly closed. This implies that \(\theta \in \mathcal{B}_T\). Define \(\zeta_n := F(\theta_n)\) and \(\zeta := F(\theta)\). In what follows, we prove that \(\zeta_n \to \zeta\) in \(W^{1,p}_0(\Omega)\) as \(k \uparrow \infty\). To accomplish this task, we invoke the problems that \(\zeta\) and \(\zeta_n\) satisfy and observe that the difference \(e_{\zeta,n} := \zeta - \zeta_n\) verifies

\[
\int_{\Omega} (\kappa(\theta_n)\nabla e_{\zeta,n} - e_{\zeta,n} u(\theta)) \cdot \nabla S dx = \int_{\Omega} \left[\zeta_n(u(\theta) - u(\theta_n)) + (\kappa(\theta_n) - \kappa(\theta))\nabla \zeta \cdot \nabla S\right] dx := (g_n, S),
\]

for all \(S \in W^{1,p}_0(\Omega)\), i.e., \(e_{\zeta,n}\) solves a heat equation with nonzero convection. Notice that, since \(\|u(\theta)\|_{L^2(\Omega)} \leq C\), we can invoke Proposition 4 immediately arrive at

\[
\|\nabla e_{\zeta,n}\|_{L^p(\Omega)} \leq C_{\delta} \|g_n\|_{W^{-1,p}(\Omega)}.
\]  

(18)

Let us now study convergence properties of \(\{g_n\}_{n \geq 0}\) as \(n \uparrow \infty\). To accomplish this task, we analyze each term compromised in the definition of \(g_n\) separately. We first invoke Hölder’s inequality and the embedding \(W^{1,p}_0(\Omega) \hookrightarrow L^{2p/(2-p)}(\Omega)\) to arrive at

\[
\int_{\Omega} e_{\zeta,n}(u(\theta) - u(\theta_n)) \cdot \nabla S dx \leq \|\zeta_n\|_{L^{2p/(2-p)}(\Omega)} \|u(\theta) - u(\theta_n)\|_{L^2(\Omega)} \|S\|_{L^{2p/(2-p)}(\Omega)} \leq C_{\zeta} \|\nabla \zeta_n\|_{L^p(\Omega)} \|u(\theta) - u(\theta_n)\|_{L^2(\Omega)} \|\nabla S\|_{L^{2p/(2-p)}(\Omega)};
\]

\(C_{\zeta}\) being the best constant in the aforementioned embedding. Let us now estimate the term \(\|u(\theta) - u(\theta_n)\|_{L^2(\Omega)}\) in the previous inequality. Invoke (5), add and subtract the term \(\sqrt{\nu(\theta)} u(\theta)\), and utilize a triangle inequality to obtain

\[
\|u(\theta) - u(\theta_n)\|_{L^2(\Omega)} \lesssim \|\sqrt{\nu(\theta)}(u(\theta) - u(\theta_n))\|_{L^2(\Omega)} \lesssim \|\nu(\theta) \frac{1}{2} u(\theta) - \nu(\theta_n) \frac{1}{2} u(\theta_n)\|_{L^2(\Omega)} + \|\nu(\theta_n) \frac{1}{2} - \nu(\theta) \frac{1}{2}\| u(\theta)\|_{L^2(\Omega)} = I + II.
\]

Since \(\theta_n \to \theta\) in \(W^{1,p}_0(\Omega)\), we invoke the compact embedding \(W^{1,p}_0(\Omega) \hookrightarrow L^2(\Omega)\) [1, Theorem 6.3, Part I] to obtain the strong convergence \(\theta_n \to \theta\) in \(L^2(\Omega)\) as \(n \uparrow \infty\). An application of [16, Lemma 2.1] thus reveals that \(I \to 0\) as \(n \uparrow \infty\). On the other hand, since \(\nu\) is continuous and uniformly bounded, the strong convergence \(\theta_n \to \theta\) in \(L^2(\Omega)\) guarantees that \(\nu(\theta_n) \to \nu(\theta)\) in \(L^2(\Omega)\) [15, Theorem 7]. Invoke the boundedness of \(\nu\), the fact that \(u(\theta) \in L^2(\Omega)\), and the Lebesgue dominated convergence to conclude that \(II \to 0\) as \(n \uparrow \infty\). To control the remaining term in \(g_n\) we proceed with similar
arguments upon noticing that \( \kappa \) is continuous and uniformly bounded, which imply that \( (\kappa(\theta_n) - \kappa(\theta))\nabla \zeta \to 0 \) in \( L^p(\Omega) \). Therefore, in view of (18), \( \zeta_n \to \zeta \) in \( W^{1,p}_0(\Omega) \) as \( n \uparrow \infty \). We have thus proved that the weak convergence \( \theta_n \to \theta \) in \( W^{1,p}_0(\Omega) \) implies the strong one \( \zeta_n \to \zeta \) in \( W^{1,p}_0(\Omega) \) as \( n \uparrow \infty \). This shows that \( \mathcal{F} \) is compact and concludes the proof.

4. Finite element approximation. In this section, we describe and analyze a finite element solution technique to approximate solutions to problem (7). We begin our analysis by introducing some terminology and a few basic ingredients [21, 26, 32]. We denote by \( \mathcal{S}_h = \{K\} \) a conforming partition, or mesh, of \( \Omega \) into closed simplices \( K \) with size \( h_K = \text{diam}(K) \). Define \( h := \max_{K \in \mathcal{S}_h} h_K \). We denote by \( T = \{\mathcal{S}_h\}_{h > 0} \) a collection of conforming and shape regular meshes \( \mathcal{S}_h \). We define \( \mathcal{S} \) as the set of internal one-dimensional interelement boundaries \( \gamma \) of \( \mathcal{S}_h \). For \( K \in \mathcal{S}_h \), let \( \mathcal{I}_K \) denote the subset of \( \gamma \) that contains the sides in \( \gamma \) which are sides of \( K \). We denote by \( \mathcal{N}_\gamma \), for \( \gamma \in \mathcal{S} \), the subset of \( \mathcal{S}_h \) that contains the two elements that have \( \gamma \) as a side. In addition, we define stars or patches associated with an element \( K \in \mathcal{S}_h \) as:

\[
N_K = \cup\{K' \in \mathcal{S}_h : \mathcal{I}_K \cap \mathcal{I}_{K'} \neq \emptyset\}, \quad N'_K = \cup\{K' \in \mathcal{S}_h : K \cap K' \neq \emptyset\}.
\]

In an abuse of notation, below we denote by \( N_K \) and \( N'_K \) either the sets themselves or the union of its elements.

Given a mesh \( \mathcal{S}_h \in T \), we define the finite element space of continuous piecewise polynomials of degree one:

\[
V_h := \{S_h \in C(\overline{\Omega}) : S_h|_K \in P_1(K) \forall K \in \mathcal{S}_h\} \cap W^{1,p}_0(\Omega),
\]

where \( p' > 2 \). Notice that, for each \( h > 0 \), \( V_h \subset W^{1,p'}_0(\Omega) \subset W^{1,p}_0(\Omega) \).

We denote by \( I_h \) the Lagrange interpolation operator and immediately notice that, since \( W^{1,p'}_0(\Omega) \hookrightarrow C(\overline{\Omega}) \), \( I_h \) is well-defined as a map from \( W^{1,p'}_0(\Omega) \) into \( V_h \) [32, Example 1.106]. The following error estimate can be found in [32, Theorem 1.103]: for each \( K \in \mathcal{S}_h \),

\[
\|S - I_hS\|_{L^p'(K)} \lesssim h_K\|\nabla S\|_{L^{p'}(K)} \quad \forall S \in W^{1,p}_0(K).
\]

With this estimate at hand, a trace identity yields, for \( \gamma \in \mathcal{S} \), the estimate

\[
\|S - I_hS\|_{L^p(\gamma)} \lesssim h_{\gamma}^{\frac{1}{2}}\|\nabla S\|_{L^p(\gamma')} \quad \forall S \in W^{1,p}_0(\gamma').
\]

To approximate the pair velocity–pressure that solves problem (10), we consider the Raviart–Thomas finite element space of order zero \( (RT_0) \):

\[
X_h := W_h \cap H_0(\text{div}, \Omega),
\]

\[
Q_h := \{q_h \in L^2(\Omega) : q_h|_K \in P_0(K) \forall K \in \mathcal{S}_h\} \cap L^2_0(\Omega),
\]

where \( W_h := \{v_h \in H(\text{div}, \Omega) : v_h|_K = a_Kx + b_K, \ a_K, b_K \in \mathbb{R}, \ b_K \in \mathbb{R}^2, \forall K \in \mathcal{S}_h\} \). The spaces \( X_h \) and \( Q_h \) satisfy the following discrete inf-sup condition [39, Theorem 13.2]: there exists \( \beta > 0 \), independent of the discretization parameter \( h \), such that

\[
\inf_{q_h \in Q_h} \sup_{v_h \in X_h} \frac{\int_{\Omega} q_h \cdot \text{div} v_h \, dx}{\|\nabla q_h\|_{L^2(\Omega)} \|v_h\|_{H(\text{div}, \Omega)}} \geq \beta > 0.
\]
Let us introduce the interpolation operator $P_h : H^1(\Omega) \cap H_0(\text{div}, \Omega) \to X_h$, which satisfies, for each $K \in \mathcal{T}_h$, the following error estimates [39, Theorem 6.3]:

\begin{align}
&\|v - P_h v\|_{L^2(K)} \lesssim h \|
abla v\|_{L^2(K)} \quad \forall v \in H^1(\Omega), \tag{23} \\
&\|\text{div}(v - P_h v)\|_{L^2(K)} \lesssim h \|
abla \text{div } v\|_{L^2(K)} \quad \forall v \in H^1(\Omega): \text{ div } v \in H^1(\Omega). \tag{24}
\end{align}

We also have the local error estimate [31, inequality (4.27)]:

\begin{equation}
\|v - P_h v\|_{L^2(\mathcal{T}_h)} \lesssim h^{\frac{1}{2}} \|
abla v\|_{L^2(\mathcal{T}_h)} \quad \forall v \in H^1(\Omega). \tag{25}
\end{equation}

In addition, we observe that, for every $v \in L^2(\Omega)$ and $w \in H(\text{div}, \Omega)$, the following density results holds:

\begin{equation}
\lim_{h \to 0} \left( \inf_{v_h \in X_h} \|v - v_h\|_{L^2(\Omega)} \right) = 0, \quad \lim_{h \to 0} \left( \inf_{w_h \in X_h} \|w - w_h\|_{L^2(\Omega)} \right) = 0. \tag{26}
\end{equation}

Having described our finite element setting, we introduce the following discrete approximation of problem (7): Find $(u_h, p_h, T_h) \in X_h \times Q_h \times V_h$ such that

\begin{equation}
\begin{cases}
\int_{\Omega} (\nu(T_h) u_h \cdot v_h - p_h \text{ div } v_h) \, dx = \int_{\Omega} f \cdot v_h \, dx & \forall v_h \in X_h, \\
\int_{\Omega} q_h \text{ div } u_h \, dx = 0 & \forall q_h \in Q_h, \\
\int_{\Omega} (\kappa(T_h) \nabla T_h \cdot \nabla S_h - T_h u_h \cdot \nabla S_h) \, dx = \langle \delta_z, S_h \rangle & \forall S_h \in V_h.
\end{cases} \tag{27}
\end{equation}

The main goal of this section is to show that, under similar assumptions to those in Theorem 6, problem (27) always has a solution for every $h > 0$. We also show that, as $h \to 0$, the sequence of solutions $(u_h, p_h, T_h)$ weakly converge, up to subsequences, to a solution of the coupled problem (7).

4.1. A discrete heat equation. In this section, we prove a discrete counterpart of Proposition 4. To accomplish this task, we first provide a discrete inf-sup condition which directly stems from [21, Proposition 8.6.2].

PROPOSITION 7 (discrete stability). Let $\xi \in L^\infty(\Omega)$ be such that (11) holds. Then, there exist $h^* > 0$ and $\epsilon > 0$ such that for all $0 < h \leq h^*$ and $R_h \in V_h$, we have

\begin{equation}
\|\nabla R_h\|_{L^p(\Omega)} \leq \tilde{C}_\xi \sup_{S_h \in V_h} \frac{\int_{\Omega} \xi \nabla R_h \cdot \nabla S_h \, dx}{\|\nabla S_h\|_{L^p(\Omega)}}, \tag{28}
\end{equation}

whenever $2 - \epsilon \leq p < 2$. Here, $\tilde{C}_\xi$ is a positive constant that is independent of $h$.

Let $\xi \in L^\infty(\Omega)$ be such that (11) holds and let $v \in L^2(\Omega)$. We introduce the following discrete version of problem (12): Find $T_h \in V_h$ such that

\begin{equation}
\int_{\Omega} (\xi \nabla T_h \cdot \nabla S_h - T_h v \cdot \nabla S_h) \, dx = \langle \delta_z, S_h \rangle \quad \forall S_h \in V_h. \tag{29}
\end{equation}

With the result of Proposition (7) at hand, in the next result we show that, under a suitable smallness assumption on the convective term, problem (29) always has a discrete solution. In addition, we show that discrete solutions are uniformly bounded with respect to the discretization parameter $h$. 

PROPOSITION 8 (well-posedness). Let $\xi \in L^\infty(\Omega)$ be such that (11) holds. There exist positive constants $h_*$ and $\epsilon$ such that, if
\begin{equation}
\tilde{C}_\xi C_e \|v\|_{L^2(\Omega)} \leq \alpha < 1,
\end{equation}
then the discrete problem (29) is well-posed for all $0 < h \leq h_*$ whenever $2 - \epsilon \leq p < 2$. In particular, we have that the solution $T_h \in V_h$ of problem (29) satisfies the estimate
\begin{equation}
\|\nabla T_h\|_{L^p(\Omega)} \leq \tilde{C}_\alpha \|\delta_z\|_{W^{-1,p}(\Omega)}, \quad \tilde{C}_\alpha = \frac{C_e}{\alpha}, \quad p \in [2 - \epsilon, 2).
\end{equation}

Proof. With the discrete inf-sup condition (28) at hand, the proof follows the same arguments as those developed for the proof of Proposition 4. For brevity, we skip the details. \hfill \Box

4.2. Existence of discrete solutions. Having derived a well-posedness result for the discrete heat equation (29), we are now in position to prove that our discrete system (27) always has a solution. In addition, we show that solutions are uniformly bounded with respect to the discretization parameter $h$.

We proceed via a fixed point argument and define, for each $h > 0$, the map $\mathcal{F}_h : V_h \rightarrow V_h$ by $\theta_h \mapsto \mathcal{F}(\theta_h) = \zeta_h$. Here, $\zeta_h$ denotes the solution to the following discrete problem: Find $\zeta_h \in V_h$ such that
\begin{equation}
\int_\Omega (\kappa(\theta_h) \nabla \zeta_h \cdot \nabla S_h - \zeta_h u_h(\theta_h) \cdot \nabla S_h) \, dx = \langle \delta_z, S_h \rangle \quad \forall S_h \in V_h.
\end{equation}
As in the continuous case, we note that the definition of $\zeta_h$ implies solving a discrete Darcy’s problem with a viscosity $\nu(\theta_h)$ depending on the prescribed discrete temperature $\theta_h$. The aforementioned discrete Darcy’s problem reads as follows: Find $(u_h(\theta_h), p_h(\theta_h)) \in X_h \times Q_h$ such that
\begin{align}
\int_\Omega (\nu(\theta_h) u_h(\theta_h) \cdot v_h - p_h(\theta_h) \, \text{div} \, v_h) \, dx &= \int_\Omega f \cdot v_h \, dx \quad \forall v_h \in X_h, \\
\int_\Omega q_h \, \text{div} \, u_h(\theta_h) \, dx &= 0 \quad \forall q_h \in Q_h.
\end{align}

In what follows, we prove that the mapping $\mathcal{F}_h$ is well-defined when it is restricted to a ball of an appropriate size. To accomplish this task, we define the ball $\mathfrak{B}_T^{h} := \{\theta_h \in V_h : \|\nabla \theta_h\|_{L^p(\Omega)} \leq \tilde{C}_\frac{1}{2} \|\delta_z\|_{W^{-1,p}(\Omega)}\}$, where $\tilde{C}_\frac{1}{2}$ is defined as in (31) with $\alpha = \frac{1}{2}$. As a final ingredient, we define
\begin{equation}
\tilde{\mathfrak{C}} := (2C_e \tilde{C}_\kappa)^{-1},
\end{equation}
where $C_e$ is defined as in (8) and $\tilde{C}_\kappa$ corresponds to the constant involved in the discrete inf-sup condition (28) with $\xi$ being replaced by $\kappa$.

LEMMA 9 ($\mathcal{F}_h$ is well-defined). Let $f$ be such that $\|f\|_{L^2(\Omega)} \leq \tilde{\mathfrak{C}} \nu_-$, where $\nu_-$ is as in (5). Then, there exist $h_* > 0$ and $\epsilon > 0$ such that the map $\mathcal{F}_h$ is well-defined on $\mathfrak{B}_T^{h}$, for all $0 < h \leq h_*$, whenever $2 - \epsilon \leq p < 2$. In addition, we have $\mathcal{F}_h(\mathfrak{B}_T^{h}) \subset \mathfrak{B}_T^{h}$.

Proof. Let $\theta_h \in \mathfrak{B}_T^{h}$. In view of the discrete inf-sup condition (22), there exists a unique discrete pair $(u_h(\theta_h), p_h(\theta_h)) \in X_h \times Q_h$ solving problem (33) [32, Proposition
Moreover, by testing \( v_h = u_h(\theta_h) \) in the first equation of (33), we arrive at the following bound for the discrete velocity field \( u_h(\theta_h) \):

\[
\| u_h(\theta_h) \|_{L^2(\Omega)} \leq \nu_-^{-1} \| f \|_{L^2(\Omega)} \leq \tilde{C} = (2C_\alpha \tilde{C}_\alpha)^{-1}.
\]

Consequently, \( u_h(\theta_h) \) is such that \( \tilde{C}_\alpha C_e \| u_h(\theta_h) \|_{L^2(\Omega)} \leq 1/2 \), i.e., \( u_h(\theta_h) \) satisfies (30) with \( \alpha = 1/2 \). We can thus utilize the results of Proposition 8 to guarantee the existence of a unique \( \zeta_h \in V_h \) solving (32). In addition, Proposition 8 also yields \( \zeta_h \in \mathcal{B}_T^h \). This concludes the proof.

We now prove the existence of discrete solutions via a fixed point argument.

**Theorem 10** (existence). Under the assumptions of Lemma 9, there exist \( h_* > 0 \) and \( \epsilon > 0 \) such that (27) admits a discrete solution \( (u_h, p_h, T_h) \in X_h \times Q_h \times V_h \) for all \( 0 < h \leq h_* \), whenever \( 2 - \epsilon \leq p < 2 \). In addition, we have that \( T_h \in \mathcal{B}_T^h \).

**Proof.** Since we are in finite dimensions, we apply Brouwer’s fixed point theorem [28, Theorem 3.2]. To be able to invoke such a theorem, we only need to verify the continuity of \( F_h \). This is achieved by repeating the arguments utilized within the proof of Theorem 6 in combination with the fact that, since we are in finite dimensions, we can pass from weak to strong convergence.

### 4.3. Convergence

We present the following convergence result.

**Theorem 11** (convergence). Let \( f \) be such that \( \| f \|_{L^2(\Omega)} \leq \nu_- \min \{ \mathcal{C}, \tilde{C} \} \), where \( \nu_- \) is given as in (5) and \( \mathcal{C} \) and \( \tilde{C} \) are defined in (17) and (34), respectively. Then, there exist \( \epsilon > 0 \), \( h_* > 0 \), and a nonrelated subsequence \( \{ T_h \}_{0<h\leq h_*} \), such that \( T_h \to T \) in \( W^{1,p}_0(\Omega) \), as \( h \downarrow 0 \), whenever \( 2 - \epsilon \leq p < 2 \). The limit point \( T \) solves problem (9) and \( (u(T), p(T)) \in H_0(\div, \Omega) \times L^2_0(\Omega) \) solves (10).

**Proof.** In view of the assumption on \( f \), Theorem 10 allows us to conclude that, for every \( h > 0 \), the discrete coupled system (27) admits at least a solution \( (u_h, p_h, T_h) \). On the other hand, Theorem 10 also guarantees that \( \{ T_h \}_{0<h\leq h_*} \), is uniformly bounded in \( W^{1,p}_0(\Omega) \) while [16, inequalities (3.13)] yield, for every \( h > 0 \), the bounds

\[
\| u_h \|_{L^2(\Omega)} \leq \nu_-^{-1} \| f \|_{L^2(\Omega)}, \quad \| p_h \|_{L^2(\Omega)} \leq \tilde{\beta}^{-1} (1 + \nu_-^{-1} \nu_+) \| f \|_{L^2(\Omega)}.
\]

Consequently, we have that (up to a subsequence) \( (u_h, p_h, T_h) \to (u, p, T) \) in \( L^2(\Omega) \times L^2_0(\Omega) \times W^{1,p}_0(\Omega) \), as \( h \downarrow 0 \), whenever \( 2 - \epsilon \leq p < 2 \).

In what follows we prove that

(i) \( (u_h, p_h) \to (u, p) \) in \( H_0(\div, \Omega) \times L^2_0(\Omega) \), as \( h \downarrow 0 \), and that

(ii) \( (u, p, T) = (u(T), p(T), T) \in H_0(\div, \Omega) \times L^2_0(\Omega) \times W^{1,p}_0(\Omega) \) solves system (7) or, equivalently, problems (9) and (10).

We first prove (i). Let \( q \in C_0^\infty(\Omega) \). We invoke the weak convergence \( u_h \to u \) in \( L^2(\Omega) \) to immediately arrive at

\[
\int_\Omega q \div u_h dx = - \int_\Omega \nabla q \cdot u_h dx \to - \int_\Omega \nabla q \cdot u dx = \int_\Omega q \div u dx, \quad h \downarrow 0.
\]

Consequently, \( u_h \to u \) in \( H(\div, \Omega) \) as \( h \downarrow 0 \). The continuity of the normal trace operator [35, Theorem 2.5] implies that \( u \cdot n|_{\partial \Omega} = 0 \) and thus that \( u \in H_0(\div, \Omega) \). The fact that \( p \in L^2_0(\Omega) \) is trivial.

The rest of the proof is dedicated to prove (ii). Let us start by proving that \( (u(T), p(T)) = (u, p) \in H_0(\div, \Omega) \times L^2_0(\Omega) \) solves Darcy’s system (10).
Let $v \in C_0^\infty(\Omega)$ and let $v_h \in X_h$. A simple computation reveals that

$$J := \left| \int_{\Omega} (\nu(T_h)u_h \cdot v_h - p_h \div v_h - \nu(T)u \cdot v + p \div v) \, dx \right|$$

$$\leq \left| \int_{\Omega} (\nu(T_h)u_h - \nu(T)u) \cdot v \, dx \right| + \left| \int_{\Omega} \nu(T_h)u_h \cdot (v_h - v) \, dx \right| + \left| \int_{\Omega} (p - p_h) \div v \, dx \right| + \left| \int_{\Omega} p_h \div (v - v_h) \, dx \right| = I + II + III + IV.$$

The density results stated in (26) immediately reveal that II, IV $\to 0$ as $h \downarrow 0$. Since $\div v \in L^2(\Omega)$ and $p_h \to p$ in $L^2_0(\Omega)$, it is also immediate that III $\to 0$ as $h \downarrow 0$. To control the term I, we first notice that

$$\int_{\Omega} (\nu(T_h)u_h - \nu(T)u) \cdot v \, dx = \int_{\Omega} (\nu(T_h) - \nu(T))u_h \cdot v \, dx + \int_{\Omega} \nu(T)(u_h - u) \cdot v \, dx.$$

Since the embedding $W_0^{1,p}(\Omega) \hookrightarrow L^q(\Omega)$ is compact for $q < 2p/(2 - p)$ [1, Theorem 6.3, Part I] and $\nu$ is continuous and uniformly bounded, we have that $\nu(T_h) \to \nu(T)$ in $L^q(\Omega)$, as $h \downarrow 0$, for $q < 2p/(2 - p)$ [15, Theorem 7]. This and the weak convergence $u_h \rightharpoonup u$ in $L^2(\Omega)$ reveal that I $\to 0$ as $h \downarrow 0$. Consequently, $J \to 0$ as $h \downarrow 0$, which reveals that the limit point $(u, p) \in H_0^1(\div, \Omega) \times L^2_0(\Omega)$ solves the first equation in (10). To prove that the velocity field $u$ satisfies the second equation in (10), we let $q \in C_0^\infty(\Omega)$ with zero mean and $q_h \in Q_h$ be its $L^2$–projection onto $Q_h$. Hence, in view of the strong convergence $q_h \to q$ in $L^2_0(\Omega)$, we obtain

$$\left| \int_{\Omega} (q \div u - q_h \div u_h) \, dx \right| \leq \left| \int_{\Omega} (q - q_h) \div u \, dx \right| + \left| \int_{\Omega} q_h \div (u - u_h) \, dx \right| \to 0,$$

as $h \downarrow 0$. Consequently, the pair $(u, p)$ solves (10).

It remains to prove that $T \in W_0^{1,p}(\Omega)$ solves (9) with $u = u(T)$. To accomplish this task, we let $S \in C_0^\infty(\Omega)$ and $S_h \in V_h$. Set $S_h = I_h S$, utilize Hölder’s inequality, the assumptions on $\kappa$, the Lebesgue dominated convergence, and standard properties of the interpolation operator $I_h$ to obtain

$$\left| \int_{\Omega} (\kappa(T)\nabla T \cdot \nabla S - \kappa(T_h)\nabla T_h \cdot \nabla S_h) \, dx \right| \leq \left| \int_{\Omega} (\kappa(T) - \kappa(T_h))\nabla T \cdot \nabla S \, dx \right| + \left| \int_{\Omega} \kappa(T_h)\nabla T_h \cdot \nabla (S - S_h) \, dx \right| \to 0, \text{ as } h \downarrow 0.$$

Finally, to prove that $\int_{\Omega} T_h u_h \cdot \nabla S_h \, dx \to \int_{\Omega} T u \cdot \nabla S \, dx$, as $h \downarrow 0$, we invoke similar arguments to those developed in the proof of Theorem 6 and the convergence result $\sqrt{\nu(T_h)}u_h(T_h) \to \sqrt{\nu(T)}u(T)$ in $L^2(\Omega)$, as $h \downarrow 0$, which follows from (2.23) in [16, Lemma 2.1]. This proves that $T \in W_0^{1,p}(\Omega)$ solves (9) with $u = u(T)$ and concludes the proof.

5. A posteriori error analysis. In this section, we devise and analyze an a posteriori error estimator for the coupled system (7). We obtain a global reliability estimate and investigate local efficiency results. To perform an analysis, in addition to the assumptions stated in (5), we shall require that:

- The thermal diffusivity $\kappa$ is a positive constant, and
- The forcing term $f \in H^1(\Omega)$ and $\|f\|_{L^2(\Omega)} \leq \nu_\ast \min\{\mathcal{C}, \mathcal{E}\}$; cf. Theorem 11.
In what follows we comment on the assumption $f \in H^1(\Omega)$ (see also the discussion in [31, Section 4]): To obtain the identity (50) we utilize the Green’s formula of [35, Theorem 2.11, Chapter I] on each element $K \in \mathcal{T}$. [35, Theorem 2.11, Chapter I] also guarantees that the tangential trace $\mathcal{T}_\tau : v \rightarrow v \cdot \tau_{\partial \Omega}$ is a linear and continuous operator from $H(\text{curl}, \Omega)$ into $H^{-1/2}(\Omega)$ for any Lipschitz domain $\Omega$. The additional regularity $f \in H(\text{curl}, \Omega)$ would thus seem sufficient. However, in order to have a local and integral representation of the residual on the interior sides $\gamma$ we assume that $f \in H^1(\Omega)$ so that the interelement residuals $[(f - \nu(T_h)u_h) \cdot \tau]$, defined in (73), are well-defined in $L^2(\gamma)$.

The existence of a solution $(u, p, T) \in H_0(\text{div}, \Omega) \times L^2(\Omega) \times W^{1,p}_0(\Omega)$ to system (7) is guaranteed by Theorem 6 for $p < 2$. Theorem 10 guarantees the existence of $\epsilon > 0$ and $h_*$ such that the discrete problem (27) admits a solution $(u_h, p_h, T_h) \in \mathbf{X}_h \times Q_h \times V_h$ for every $0 < h < h_*$ and $2 - \epsilon \leq p < 2$. Within our a posteriori error analysis setting, since we will not be dealing with uniform refinement, the parameter $h$ does not bear the meaning of a mesh size. It can thus be thought as $h = 1/k$, where $k \in \mathbb{N}$ is the index set in a sequence of refinements of an initial mesh or partition $\mathcal{T}_h$.

5.1. A posteriori error estimators. In this section, we devise an a posteriori error estimator for the finite element approximation (27) of system (7). The proposed error estimator will be decomposed as the sum of three individual contributions: one contribution that accounts for the discretization of the heat equation with convection and two contributions related to the discretization of Darcy’s system.

Let us begin our analysis by introducing some notation. Let $w_h$ be a discrete tensor valued function and let $\gamma \in \mathcal{T}$ be an internal side. We define the jump or interelement residual of $w_h$ on $\gamma$ by

$$[w_h \cdot n] := n^+ \cdot w_h|_{K^+} + n^- \cdot w_h|_{K^-},$$

where $n^+$ and $n^-$ denote the unit normals to $\gamma$ pointing towards $K^+$ and $K^-$, respectively; $K^+, K^- \in \mathcal{T}_h$ are such that $K^+ \neq K^-$ and $\partial K^+ \cap \partial K^- = \gamma$. Similarly,

$$[w_h \cdot \tau] := \tau^+ \cdot w_h|_{K^+} + \tau^- \cdot w_h|_{K^-},$$

where $\tau^+$ and $\tau^-$ denote the unit tangents to $\gamma$; cf. Figure 1. Notice that $\tau^+$ and $n^+$ are orthogonal; similarly $\tau^-$ and $n^-$.

![Fig. 1. Representation of the tangent and normal vectors, respectively, on $K^+$ and $K^-$.](image)

5.1.1. Heat equation with convection: local indicators and a posteriori error estimator. Let $K \in \mathcal{T}_h$ be a simplex and $\gamma \in \mathcal{T}$ be an internal side. We define the element residual $\mathcal{R}_K$ and the interelement residual $\mathcal{J}_\gamma$ as

$$\mathcal{R}_K := (-\nabla T_h \cdot u_h - T_h \text{div } u_h)|_K, \quad \mathcal{J}_\gamma := [\left(\kappa \nabla T_h - T_h u_h\right) \cdot n].$$

With the residuals $\mathcal{R}_K$ and $\mathcal{J}_\gamma$ at hand, we define a local indicator $\mathcal{E}_{p,K}$ associated to the underlying finite element discretization of the heat equation on the basis of three
scenarios. First, if \( z \in K \) and \( z \) is not a vertex of \( K \), then
\[
E_{p,K} := \left( h_K^{2-p} + h_K^p \| \mathcal{R}_{K} \|_{L^p(K)}^p + h_K \| \mathcal{J}_f \|_{L^p(\partial K \setminus \partial \Omega)}^p \right)^{\frac{1}{p}}. 
\]

Second, if \( z \in K \) and \( z \) is a vertex of \( K \), then
\[
E_{p,K} := \left( h_K^p \| \mathcal{R}_{K} \|_{L^p(K)}^p + h_K \| \mathcal{J}_f \|_{L^p(\partial K \setminus \partial \Omega)}^p \right)^{\frac{1}{p}}. 
\]

Third, if \( z \notin K \), then the indicator \( E_{p,K} \) is defined as in (37).

The following comments are now in order. We first recall that we consider our elements \( K \) to be closed sets. On the other hand, the Lagrange interpolation operator \( I_h \) is well-defined over the space \( W_0^{1,p'}(\Omega) \) with \( p' > 2 \). Since \( I_h \) is constructed by matching the point values at the Lagrange nodes, we have the basic property
\[
(S - I_h S)(z) = 0 \quad \forall S \in W_0^{1,p'}(\Omega), \; p' > 2, \forall K \in \mathcal{N}_h. 
\]

Here \( z \) denotes a vertex of \( K \). This simple observation points in the direction of explaining the discrepancy between definitions (36) and (37).

With the previous indicators at hand, we define the corresponding error estimator
\[
E_{p,\mathcal{S}} := \left( \sum_{K \in \mathcal{S}} E_{p,K} \right)^{\frac{1}{p}}, \quad p < 2. 
\]

5.1.2. Darcy’s problem: local indicators and a posteriori error estimator. The devising and analysis of residual-type a posteriori error estimates for Raviart–Thomas finite element approximations of Darcy’s problem are not as simple as for the Laplace’s equation. In fact, two difficulties prevent the success of the straightforward application of frequently used arguments. First, traces of functions in \( \mathbf{H}(\text{div}, \Omega) \) are only contained in \( H^{-1/2}(\partial \Omega) \) [35, Theorem 2.5] and, for an internal side \( \gamma \), the corresponding jump term \([p_h \mathbf{n}]\) does not belong to \( H^{1/2}(\gamma) \) [22, Section III.3.3]; \( \mathbb{I} \) denotes the identity matrix. The second difficulty is given the fact that the space \( \mathbf{H}(\text{div}, \Omega) \) is anisotropic [20]; for solenoidal functions the \( \mathbf{H}(\text{div}, \Omega) \)-norm and the \( L^2(\Omega) \)-norm coincide. The authors of [20] circumvent these difficulties and devise an a posteriori error estimator that is reliable and efficient in suitable mesh-dependent norms; see [20, inequality (3.12)] and [20, Theorem 3.3]. However, the devised error estimator for the natural norm in \( \mathbf{H}(\text{div}, \Omega) \times L^2(\Omega) \) is only reliable; the derived efficiency estimate [20, inequality (4.20)], that involves a negative power of \( h \), is not optimal. Later, the author of [23] provides reliable and efficient a posteriori error estimates in the natural norm in \( \mathbf{H}(\text{div}, \Omega) \times L^2(\Omega) \); the difficulties arising from the anisotropy of the norm are circumvented by utilizing a Helmholtz decomposition of square-integrable tensors.

Inspired by the developments in [31, Section 4], and in view of the assumption that \( f \in \mathbf{H}^1(\Omega) \), we apply the \( \mathbf{curl} \) operator to the the first equation of Darcy’s system (10), in its strong form, to obtain
\[
\mathbf{curl}(\nu(T) \mathbf{u}) = \mathbf{curl} \; f \quad \text{in} \; \Omega. 
\]

Let \( K \in \mathcal{N}_h \) and \( \gamma \in \mathcal{S} \). We define the element and interelement residuals
\[
\mathcal{R}_K := \mathbf{curl}(f - \nu(T_h) \mathbf{u}_h), \quad \mathcal{J}_\gamma := \| (f - \nu(T_h) \mathbf{u}_h) \cdot \mathbf{n} \|,
\]
\[
\mathcal{B}_K := f - \nu(T_h) \mathbf{u}_h - \nabla p_h, \quad \mathcal{J}_\gamma := \| p_h \mathbf{n} \|. 
\]
With these ingredients at hand, we define local error indicators

\[
\varepsilon_K := \left( h_K^2 \|\mathcal{G}_K\|_{L^2(\partial K)}^2 + h_K \|\mathcal{J}_\gamma\|_{L^2(\partial K \setminus \partial \Omega)}^2 \right)^{\frac{1}{2}},
\]

\[
\delta_K := \left( h_K^2 \|\mathcal{H}_K\|_{L^2(\partial K)}^2 + h_K \|\mathcal{J}_\xi\|_{L^2(\partial K \setminus \partial \Omega)}^2 \right)^{\frac{1}{2}},
\]

and a posteriori error estimators associated to Darcy’s system as

\[
\mathcal{E}_\mathcal{T} := \left( \sum_{K \in \mathcal{T}} \varepsilon_K^2 \right)^{\frac{1}{2}}, \quad \mathcal{E}_D := \left( \sum_{K \in \mathcal{T}} \delta_K^2 \right)^{\frac{1}{2}}.
\]

### 5.2. Reliability estimates

In this section, we obtain a global reliability estimate for the total a posteriori error estimator

\[
\mathcal{E}_\mathcal{T} := \varepsilon_{\rho,\mathcal{T}} + \varepsilon_{\mathcal{T}} + \delta_{\mathcal{T}}.
\]

The following result is instrumental to perform our analysis.

**Lemma 12** (auxiliary result). Let \( \mathbf{v} \in V(\Omega) \), where \( V(\Omega) \) is defined as in Section 2. Then, there exists a unique function \( \mathbf{v} \in H^1_0(\Omega) \) such that

\[
\mathbf{v} = \text{curl} \mathbf{\vartheta}, \quad \| \mathbf{\vartheta} \|_{H^1(\Omega)} \lesssim \| \mathbf{v} \|_{L^2(\Omega)}.
\]

The hidden constant is independent of \( \mathbf{\vartheta} \) and \( \mathbf{v} \).

**Proof.** The proof of the existence of a function \( \mathbf{\vartheta} \in H^1(\Omega) \) satisfying the desired properties can be found in [35, Chapter I, Theorem 3.1]. The correction of \( \mathbf{\vartheta} \in H^1(\Omega) \) satisfying the needed boundary condition is available in [31, Appendix A]. \( \Box \)

As a final preparatory step, we define the discretization errors associated to the temperature, the velocity, and the pressure, respectively, as follows:

\[
e_T := T - T_h, \quad e_u := \mathbf{u} - \mathbf{u}_h, \quad e_p := p - p_h.
\]

We are now ready to enunciate and prove the main result of this section.

**Theorem 13** (global reliability). Let \( (\mathbf{u}, p, T) \in H_0(\text{div}, \Omega) \times L^2_\Omega(\Omega) \times W^{1,p}_0(\Omega) \) be a solution to (7) with a forcing term \( \mathbf{f} \), which is such that \( \| \mathbf{f} \|_{L^2(\Omega)} \leq \nu \min \{ \mathcal{C}, \mathcal{C} \} \). Let \( (\mathbf{u}_h, p_h, T_h) \in X_h \times Q_h \times V_h \) be a solution to the discrete system (27) for \( 0 < h \leq h_* \). Assume that

\[
\mathcal{C}^{-1} \| \mathbf{u}_h \|_{L^2(\Omega)} \leq \rho, \quad 0 < \rho < 1,
\]

where \( \mathcal{C} = (2C_c C_\alpha)^{-1} \), \( C_c \) is the best constant in the Sobolev embedding \( W^{1,p}_0(\Omega) \hookrightarrow L^{2p/(2-p)}(\Omega) \), and \( C_\alpha \) is defined as in (15) with \( \alpha = \frac{1}{2} \). Assume, in addition, that

\[
C_L \| \delta_{\mathbf{u}} \|_{W^{1,p}(\Omega)} \| \mathbf{u} \|_{L^{p}(\Omega)} \leq \varrho (1 - \rho) \nu - \mathcal{C}^2, \quad 0 < \varrho < 1,
\]

where \( \frac{1}{p} + \frac{1}{p'} = 1 \) and \( C_L \) denotes the Lipschitz constant of \( \nu \). Then

\[
\| \nabla e_T \|_{L^p(\Omega)} + \| e_u \|_{L^2(\Omega)} + \| e_p \|_{L^2(\Omega)} \lesssim \mathcal{E}_{\mathcal{T}}.
\]

Here, the hidden constant is independent of continuous and discrete variables, the size of the elements in the mesh \( \mathcal{T}_h \), and \( \# \mathcal{T}_h \).
Proof. We begin by controlling the temperature error \( \| \nabla e_T \|_{L^p(\Omega)} \). To accomplish this task, we invoke equation (9), an elementwise integration by parts formula, and Galerkin orthogonality to obtain

\[
(48) \quad \int_{\Omega} (\kappa \nabla e_T + e_T \mathbf{e}_u - e_T \mathbf{u} - T \mathbf{e}_u) \cdot \nabla S \, dx = \langle \delta T, S - I_h \rangle S
\]

\[
+ \sum_{K \in \mathcal{T}} \int_K R_K (S - I_h S) \, dx + \sum_{\gamma \in \mathcal{F}_\gamma} \int_{\gamma} J_\gamma (S - I_h S) \, ds
\]

for every \( S \in W_0^{1,p'}(\Omega) \). The element and interelement residuals, \( R_K \) and \( J_\gamma \), respectively, are defined in (35). Hence, the inf-sup condition (13), Hölder’s inequality, and the local interpolation bounds (20) and (21) yield

\[
\| \nabla e_T \|_{L^p(\Omega)} \leq C_\kappa \sup_{S \in W_0^{1,p'}(\Omega)} \frac{1}{\| \nabla S \|_{L^p(\Omega)}} \int_{\Omega} \kappa \nabla e_T \cdot \nabla S \, dx
\]

\[
\leq C_\kappa \left( \| e_T \|_{L^{2p}(\Omega)} \left( \| e_u \|_{L^2(\Omega)} + \| \mathbf{u} \|_{L^2(\Omega)} \right) + \| T \|_{L^{2p}(\Omega)} \| e_u \|_{L^2(\Omega)} + C \mathcal{E}_{p,\mathcal{F}} \right)
\]

where \( C > 0 \). In view of this estimate, the embedding \( W_0^{1,p}(\Omega) \hookrightarrow L^{2p}(\Omega) \), the bound \( \| \mathbf{u} \|_{L^2(\Omega)} \leq C = (2C_\kappa C_{\kappa})^{-1} \), and the assumption (45), we deduce that

\[
(49) \quad (1 - \rho) \| \nabla e_T \|_{L^p(\Omega)} \leq 4C_\kappa^2 C_{\kappa} \| \delta z \|_{W^{-1,p}(\Omega)} \| e_u \|_{L^2(\Omega)} + 2C \kappa \mathcal{E}_{p,\mathcal{F}}
\]

where \( C_\kappa \) denotes the best constant in the embedding \( W_0^{1,p}(\Omega) \hookrightarrow L^{2p}(\Omega) \) and \( C_\kappa \) is defined as in (15) with \( \alpha = \frac{1}{2} \).

We now control the velocity error. Let \( \mathbf{v} \in \mathbf{V}(\Omega) \), where \( \mathbf{V}(\Omega) \) is defined in Section 2. An application of Lemma 12 yields the existence of a unique function \( \vartheta \in H_0^1(\Omega) \) such that \( \mathbf{v} = \text{curl} \vartheta \) and \( \| \vartheta \|_{H^1(\Omega)} \lesssim \| \mathbf{v} \|_{L^2(\Omega)} \). Utilize the pair \( (\mathbf{v}, 0) \) as a test pair in problem (10) to deduce, in view of an elementwise integration by parts formula based on [35, Theorem 2.11, Chapter I] and Galerkin orthogonality, the identity

\[
(50) \quad \int_{\Omega} \left( \nu(T_h) \mathbf{e}_u + (\nu(T) - \nu(T_h)) \mathbf{u} \right) \cdot \mathbf{v} \, dx
\]

\[
= \sum_{K \in \mathcal{T}} \int_K R_K (\vartheta - I_h \vartheta) \, dx + \sum_{\gamma \in \mathcal{F}_\gamma} \int_{\gamma} J_\gamma (\vartheta - I_h \vartheta) \, ds.
\]

Here, \( I_h : H_0^1(\Omega) \rightarrow V_h \) denotes the Clément interpolation operator [21, 25]. We recall that the element and interelement residuals, \( R_K \) and \( J_\gamma \), respectively, are defined in (39). Since \( \nu \) is uniformly bounded, namely, \( \nu \) satisfies (5), (50) in combination with Hölder’s inequality, standard interpolation error estimates for \( I_h \), and the estimate \( \| \vartheta \|_{H^1(\Omega)} \lesssim \| \mathbf{v} \|_{L^2(\Omega)} \), which follows from Lemma 12, allow us to obtain that

\[
(51) \quad \nu_\cdot \| e_u \|_{L^2(\Omega)} \leq C_{\kappa} \| \nabla e_T \|_{L^p(\Omega)} \| \mathbf{u} \|_{L^p(\Omega)} + C \mathcal{E}_{p,\mathcal{F}}, \quad C > 0.
\]

Replacing this estimate into (49) immediately yields \( \| \nabla e_T \|_{L^p(\Omega)} \lesssim \mathcal{E}_{p,\mathcal{F}} + \mathcal{E}_{\mathcal{F}} \), upon utilizing assumption (46). This bound combined with estimate (51) and assumption (46) yield the a posteriori error estimate \( \| e_u \|_{L^2(\Omega)} \lesssim \mathcal{E}_{p,\mathcal{F}} + \mathcal{E}_{\mathcal{F}} \).
We finally control the pressure error. Since \( e_p \in L^2_0(\Omega) \), we invoke the inf-sup condition between \( H^1_0(\Omega) \) and \( L^2_0(\Omega) \) \cite[Corollary 2.4, Chapter I]{35}, \cite[Corollary B.71]{32} to conclude the existence of \( v \in H^1_0(\Omega) \subset H_0(\text{div}, \Omega) \) such that

\[
\|e_p\|_{L^2(\Omega)}^2 = \int_{\Omega} e_p \, \text{div} \, v \, dx, \quad \|\nabla v\|_{L^2(\Omega)} \lesssim \|e_p\|_{L^2(\Omega)}.
\]

Set \((v, 0)\) as a test pair in Darcy’s problem \((10)\) and utilize an elementwise integration by parts formula to obtain

\[
\begin{align*}
(52) \quad \int_{\Omega} \nu(T_h) e_u \cdot v \, dx + \int_{\Omega} (\nu(T) - \nu(T_h)) u \cdot v \, dx - \int_{\Omega} e_p \, \text{div} \, v \, dx \\
= \sum_{K \in \mathcal{T}_h} \int_K \mathcal{R}_K \cdot (v - P_h v) \, dx - \sum_{\gamma \in \mathcal{F}_h} \int_{\gamma} \mathcal{J}_\gamma \cdot (v - P_h v) \, ds,
\end{align*}
\]

where \( P_h : H^1(\Omega) \cap H_0(\text{div}, \Omega) \to \mathbf{X}_h \) denotes the interpolation operator introduced in Section 4. On the basis of the identities \((52)\) and \((53)\), Hölder’s inequality, the Lipschitz property of \( \nu \), the embedding \( W^{1,p}_0(\Omega) \hookrightarrow L^{2p/(2-p)}(\Omega) \), the interpolation error estimates \((23)\) and \((25)\), and assumption \((46)\), we obtain the estimate

\[
\|e_p\|_{L^2(\Omega)} \lesssim \|e_u\|_{H^2(\Omega)} + \|\nabla v \|_{L^\infty(\Omega)} + \mathcal{E}_{\mathcal{T}}.
\]

This estimate and the bound \( \|e_u\|_{H^2(\Omega)} + \|\nabla v \|_{L^\infty(\Omega)} \lesssim \mathcal{E}_{\mathcal{T}} + \mathcal{E}_{\mathcal{N}} \), which follows from \((49)\) and \((51)\), allow us to conclude the desired a posteriori error estimate \((47)\). \(\square\)

**5.3. Efficiency estimates.** In this section, we study efficiency properties of the a posteriori error estimator \( \mathcal{E}_{\mathcal{T}} \), defined in \((44)\), by examining each of its contributions separately. To accomplish this task, we will invoke standard residual estimation techniques which are based on the consideration of suitable bubble functions \cite{43,3}. Before proceeding with such an analysis, we introduce the following notation: for an edge or triangle \( G \), let \( V(G) \) be the set of vertices of \( G \). With this notation at hand, we define, for \( K \in \mathcal{T}_h \) and \( \gamma \in \mathcal{F}_h \), the standard element and edge bubble functions

\[
(54) \quad \varphi_K = 27 \prod_{v \in V(K)} \lambda_v, \quad \varphi_\gamma = 4 \prod_{v \in V(\gamma)} \lambda_v|_{K'}, \quad K' \subset \mathcal{N}_\gamma,
\]

respectively, where \( \lambda_v \) are the barycentric coordinates of \( K \). We recall that \( \mathcal{N}_\gamma \) corresponds to the patch composed of the two elements of \( \mathcal{T}_h \) sharing \( \gamma \).

Inspired by references \cite{10,13}, we also introduce some suitable bubble functions which are particular useful for analyzing the indicators associated to the discretization of the heat equation with convection \((9)\). Given \( K \in \mathcal{T}_h \), we define the element bubble function \( \phi_K \) as

\[
(55) \quad \phi_K(x) := h_K^{-2}|x - z|^2 \varphi_K(x) \text{ if } z \in K, \quad \phi_K(x) := \varphi_K(x) \text{ if } z \notin K.
\]

Given \( \gamma \in \mathcal{F}_h \), we define the edge bubble function \( \phi_\gamma \) as

\[
(56) \quad \phi_\gamma(x) := h_\gamma^{-2}|x - z|^2 \varphi_\gamma(x) \text{ if } z \in \mathcal{N}_\gamma, \quad \phi_\gamma(x) := \varphi_\gamma(x) \text{ if } z \notin \mathcal{N}_\gamma,
\]

where \( \mathcal{N}_\gamma \) denotes the interior of \( \mathcal{N}_\gamma \). We recall that the Dirac measure \( \delta_z \) is supported at \( z \in \Omega \); it can thus be supported on the interior, an edge, or a vertex of an element \( K \) of the triangulation \( \mathcal{T}_h \).
Given $\gamma \in \mathcal{S}$, we introduce the continuation operator $\Pi_{\gamma} : L^\infty(\gamma) \rightarrow L^\infty(\mathcal{N}_{\gamma})$ defined in [42, Section 3]. This operator maps polynomials onto piecewise polynomials of the same degree and it will be useful for controlling the involved jump terms.

We now provide the following result [10, Lemmas 3.1 and 3.2].

**Lemma 14** (bubble function properties). Let $K \in \mathcal{T}_h$, $\gamma \in \mathcal{S}$, and $r \in (1, \infty)$. If $S_h|_K \in \mathbb{P}_1(K)$ and $R_h|_{\gamma} \in \mathbb{P}_1(\gamma)$, then

\[
\|S_h\|_{L^r(K)} \lesssim \|S_h \phi_K^\gamma\|_{L^r(K)} \lesssim \|S_h\|_{L^r(K)},
\]

\[
\|R_h\|_{L^r(\gamma)} \lesssim \|R_h \phi_{\gamma}^R\|_{L^r(\gamma)} \lesssim \|R_h\|_{L^r(\gamma)},
\]

\[
\|\phi_{\gamma} \Pi_{\gamma}(R_h)\|_{L^r(\mathcal{N}_{\gamma})} \lesssim h_{\gamma}^2 \|R_h\|_{L^r(\gamma)}.
\]

**5.3.1. Local estimates for $\mathcal{E}_{p,K}$**. We now investigate local estimates for the local error indicators $\mathcal{E}_{p,K}$ defined in (36) and (37).

**Theorem 15** (local estimate for $\mathcal{E}_{p,K}$). Let $(u, p, T) \in H_0(div, \Omega) \times L^2_0(\Omega) \times W_0^{1,p}(\Omega)$ be a solution to (7) with a forcing term $f$, which is such that $\|f\|_{L^2(\Omega)} \leq \nu_\gamma \min(\mathcal{C}, \mathcal{E})$. Let $(u_h, p_h, T_h) \in \mathbb{X}_h \times Q_h \times V_h$ be a solution to the discrete system (27) for $0 < h \leq h_*$. Then, for $K \in \mathcal{T}_h$, the local indicator $\mathcal{E}_{p,K}$ satisfies the bound

\[
\mathcal{E}_{p,K} \lesssim \|\nabla e_T\|_{L^p(\mathcal{N}_{\gamma}^*)} + \|e_T\|_{L^{2p}(\mathcal{N}_{\gamma}^*)} + \|e_u\|_{L^2(\mathcal{N}_{\gamma}^*)},
\]

where $\mathcal{N}_{\gamma}^*$ is defined in (19). The hidden constant is independent of continuous and discrete solutions $(u, p, T)$ and $(u_h, p_h, T_h)$, respectively, the size of the elements in the mesh $\mathcal{T}_h$, and $\# \mathcal{T}_h$.

**Proof.** We begin by noticing that similar arguments to the ones used to derive (48) yield the identity

\[
\int_{\Omega} (\kappa \nabla e_T \cdot \nabla S - Te_u \cdot \nabla S - e_T u_h \cdot \nabla S) \, dx = \langle \delta_z, S \rangle + \sum_{K \in \mathcal{T}} \int_K \mathcal{R}_K S \, dx + \sum_{\gamma \in \mathcal{S}} \int_{\gamma} \mathcal{J}_{\gamma} S \, ds,
\]

for every $S \in W_0^{1,p'}(\Omega)$.

On the basis of identity (58), we proceed in three steps.

**Step 1.** Let $K \in \mathcal{T}_h$. In what follows, we bound the term $h_{\gamma} \|\mathcal{R}_K\|_{L^p(K)}$ in (36)–(37). To accomplish this task, we set $S = \phi_K \mathcal{R}_K$ in (58), where $\phi_K$ is the bubble function defined in (55). Since $\phi_K$ is such that $\langle \delta_z, \phi_K \mathcal{R}_K \rangle = 0$, we thus obtain

\[
\|\mathcal{R}_K\|_{L^p(K)}^2 \lesssim \|\nabla e_T\|_{L^p(K)} + \|e_T\|_{L^{2p}(K)} \|e_u\|_{L^2(K)} + \|e_T\|_{L^{2p}(K)} \|e_u\|_{L^2(K)} \|\nabla (\phi_K \mathcal{R}_K)\|_{L^p(K)},
\]

where we have used the first estimate in Lemma 14. To control $\|\nabla (\phi_K \mathcal{R}_K)\|_{L^p(K)}$, we utilize standard inverse estimates [21, Lemma 4.5.3] and properties of $\phi_K$ to obtain

\[
\|\nabla (\phi_K \mathcal{R}_K)\|_{L^p(K)} \lesssim h_{\gamma}^{-1} \|\phi_K \mathcal{R}_K\|_{L^p(K)} \lesssim h_{\gamma}^{\frac{1}{2} - 2} \|\mathcal{R}_K\|_{L^2(K)}.
\]

In view of this bound, the estimate $h_{\gamma}^{1 - \frac{2}{p}} \|\mathcal{R}_K\|_{L^p(K)} \lesssim \|\mathcal{R}_K\|_{L^2(K)}$ yields

\[
h_K \|\mathcal{R}_K\|_{L^p(K)} \lesssim \|\nabla e_T\|_{L^p(K)} + \|e_T\|_{L^{2p}(K)} + \|e_u\|_{L^2(K)},
\]
upon utilizing the stability estimate (15) and the fact that \( u_h \) is uniformly bounded in \( L^2(\Omega) \).

**Step 2.** Let \( K \in \mathcal{T}_h \) and \( \gamma \in \mathcal{S}_K \). We now bound \( h_K^{\frac{1}{2}} \| J_\gamma \|_{L^p(\gamma)} \) in (36)-(37). To accomplish this task, we utilize the bubble function \( \phi_\gamma \) defined in (56). In fact, let us set \( S = \phi_\gamma \Pi_\gamma (J_\gamma) \) in (58). We recall that \( \Pi_\gamma \) denotes the continuation operator of [42, Section 3]. Standard arguments thus yield

\[
\| J_\gamma \|_{L^2(\gamma)}^2 \lesssim \sum_{K' \in \mathcal{N}_\gamma} h_{K'}^{-1} \left( \| \nabla e_T \|_{L^p(K')} + \| e_T \|_{L^w(K')} + \| e_u \|_{L^2(K')} \right) \| \phi_\gamma \Pi_\gamma (J_\gamma) \|_{L^p(K')},
\]

where, to simplify notation, we have defined \( m = 2p/(2 - p) \). We now notice that

\[
\| \phi_\gamma \Pi_\gamma (J_\gamma) \|_{L^p(K')} \lesssim h_{K'}^{\frac{1}{2}} \| J_\gamma \|_{L^p(\gamma)}, \quad \| J_\gamma \|_{L^p(\gamma)} \lesssim h_{K'}^{-\frac{1}{2}} \| J_\gamma \|_{L^2(\gamma)}.
\]

The first estimate follows immediately from Lemma 14 and the second one is a consequence of a scaled–trace inequality and an inverse estimate. With these estimates at hand, we can thus obtain

\[
\| J_\gamma \|_{L^2(\gamma)}^2 \lesssim \sum_{K' \in \mathcal{N}_\gamma} \left( \| \nabla e_T \|_{L^p(K')} + \| e_T \|_{L^w(K')} + \| e_u \|_{L^2(K')} \right) h_{K'}^{-\frac{1}{2} + p - \frac{1}{2}} \| J_\gamma \|_{L^2(\gamma)}.
\]

This bound combined with the estimate \( h_K^{\frac{2}{p}} \| J_\gamma \|_{L^p(\gamma)} \lesssim \| J_\gamma \|_{L^2(\gamma)} \) allow us to conclude the desired estimate

\[
(60) \quad h_K^{\frac{2}{p}} \| J_\gamma \|_{L^p(\gamma)} \lesssim \sum_{K' \in \mathcal{N}_\gamma} \left( \| \nabla e_T \|_{L^p(K')} + \| e_T \|_{L^w(K')} + \| e_u \|_{L^2(K')} \right) h_{K'}^{-\frac{1}{2} + p - \frac{1}{2}} \| J_\gamma \|_{L^2(\gamma)}.
\]

**Step 3.** Let \( K \in \mathcal{T}_h \). We now bound the remaining term \( h_K^{\frac{2}{p}} \) in (36). We first notice that, if \( K \cap \{ z \} = \emptyset \), then the desired estimate (57) follows directly from the previous two steps. If, on the other hand, \( K \cap \{ z \} \neq \emptyset \) and \( z \in K \) is not a vertex of \( K \), then we must obtain a bound for the aforementioned term. To accomplish this task, we invoke the smooth function \( \mu \) introduced in [13, Section 3] which is such that

\[
(61) \quad \mathcal{M}_\mu := \text{supp}(\mu) \subset \mathcal{N}_K, \quad \mu(z) = 1, \quad \| \mu \|_{L^\infty(\Omega_{int})} = 1, \quad \| \nabla \mu \|_{L^\infty(\Omega_{int})} \lesssim h_K^{-1}.
\]

In addition to (61), the function \( \mu \) satisfies the estimates

\[
(62) \quad \| \mu \|_{L^p(\mathcal{N}_K)} \lesssim h_K^{\frac{2}{p}}, \quad \| \nabla \mu \|_{L^p(\mathcal{N}_K)} \lesssim h_K^{\frac{2}{p} - 1}, \quad \| \mu \|_{L^p(\gamma)} \lesssim h_K^{\frac{2}{p}}.
\]

To bound the term \( h_K^{\frac{2}{p}} \), we also need to introduce the set

\[
\mathcal{S}(\mathcal{N}_K) := \{ \gamma \in \mathcal{S} : \gamma \in \partial \mathcal{K}', \mathcal{K}' \in \mathcal{N}_K^* : \gamma \notin \partial \mathcal{N}_K^* \}.
\]

Set \( S = \mu \) in (58) and then invoke Hölder’s inequality and the estimates for \( \mu \) stated in (61) and (62) to obtain

\[
1 \lesssim \sum_{K' \in \mathcal{N}_K} \left[ \left( \| \nabla e_T \|_{L^p(K')} + \| e_T \|_{L^w(K')} + \| e_u \|_{L^2(K')} \right) \| \nabla \mu \|_{L^p(K')} \right. \\
+ \| \mathcal{R}_K \|_{L^p(K')} \| \mu \|_{L^p(K')} \right] + \sum_{\gamma \in \mathcal{S}(\mathcal{N}_K)} \| J_\gamma \|_{L^p(\gamma)} \| \mu \|_{L^p(\gamma)} \lesssim \sum_{\gamma \in \mathcal{S}(\mathcal{N}_K)} \left[ h_K^{\frac{2}{p}} \| J_\gamma \|_{L^p(\gamma)} + \| \mathcal{R}_K \|_{L^p(K')} + \| \mu \|_{L^p(T')} + \| e_u \|_{L^2(K')} + h_K^{\frac{2}{p}} \| \mathcal{R}_K \|_{L^p(K')} \right].
\]
Here, \( m = 2p/(2 - p) \). In view of estimates (59) and (60), we can thus arrive at

\[
\tag{63}
\hat{h}_K^{2m} \lesssim \sum_{K' \in \mathcal{N}_E} \left( \| \nabla e_T \|_{L^p(K')} + \| e_T \|_{L^\infty(K')} + \| e_u \|_{L^2(K')} \right).
\]

We conclude the proof by gathering the estimates (59), (60), and (63).

\[ \blacksquare \]

**5.3.2. Local estimates for \( \varepsilon_K \).** We now analyze local estimates for the indicator \( \varepsilon_K \) defined in (42). As an instrumental ingredient, we introduce a suitable approximation of the term \( \nu(T_h) \) involved in the definition of the element residual \( \mathcal{R}_E \) given in (40). For \( K \in \mathcal{T}_h \), we define the linear approximation \( \nu_h : W^{1,p}(K) \ni S \to \nu_h(S) \in \mathbb{P}_1(K) \) by

\[
\nu_h(S)(x) := \frac{1}{|K|} \int_K \nu(S(y)) \, dy + \left[ \frac{1}{|K|} \int_K (\nabla \nu(S))(y) \, dy \right] \cdot (x - c).
\]

Here, \(|K|\) and \(c\) denote the Lebesgue measure and the center of \( K \), respectively. We notice that \(|x - c| \leq h_K\) and observe that \( \nu_h \) is invariant under affine transformations and that, if \( \nu(S)|_{K} \in \mathbb{P}_1(K) \), then \( \nu_h(S) = \nu(S) \) in \( K \) [31, Section 4.2].

In what follows, and in addition to the assumptions stated in Section 3.1, we will assume that \( \nu \in W^{2,\infty}(\mathbb{R}) \). This immediately implies the existence of a real number \( \nu_+ \) such that \( \nu'(s) \leq \nu_+ \) for all \( s \in \mathbb{R} \). In addition, we have that \( \nu' \in C^{0,1}([\mathbb{R}] \) with a Lipschitz constant \( C_L^\nu \). With the assumption that \( \nu \in W^{2,\infty}(\mathbb{R}) \) at hand, basic computations, on the basis of definition (64) and (5), reveal the following bound:

\[
\tag{65}
\| \nu_h(S) \|_{L^{\infty}(K)} \leq \nu_+ + \nu_+ h_K |K|^{-\frac{1}{p}} \| \nabla S \|_{L^p(K)} \quad \forall S \in W^{1,p}(K).
\]

Similar arguments also yield, for \( S, R \in W^{1,p}(K) \) and \( p > 4/3 \), the following estimate:

\[
\tag{66}
\| \nu_h(S) - \nu_h(R) \|_{L^{\frac{2p}{p-2}}(K)} \leq h_K \left( \nu_+ |K|^{-\frac{1}{p}} \| \nabla (S - R) \|_{L^p(K)} \right) + C_L^\nu \| S - R \|_{L^{\frac{2p}{p-2}}(K)}.
\]

The following projection estimate is instrumental.

**Lemma 16 (projection estimate).** Let \( (u, p, T) \in H_0(\text{div}, \Omega) \times L_0^2(\Omega) \times W_0^{1,p}(\Omega) \) be a solution to (7) with a forcing term \( f \), which is such that \( \| f \|_{L^2(\Omega)} \leq \nu_+ \min\{c, c\} \).

Let \( (u_h, p_h, T_h) \in X_h \times Q_h \times V_h \) be a solution to the discrete system (27) for \( 0 < h \leq h_* \). If \( \nu \in W^{2,\infty}(\mathbb{R}) \), and (45) and (46) holds, then, for \( K \in \mathcal{T}_h \), we have

\[
\tag{67}
\| (\nu(T_h) - \nu_h(T_h))u_h \|_{L^2(K)} \lesssim \| \nu(T) - \nu(T) \|_{L^{\frac{2p}{p-2}}(K)} + \hat{h}_K^{1-\frac{1}{2}} \left( \| e_u \|_{L^2(K)} + \| \nabla e_T \|_{L^p(K)} + \| e_T \|_{L^{\frac{2p}{p-2}}(K)} \right).
\]

**Proof.** We begin with a simple application of the triangle inequality to obtain

\[
\tag{68}
\| (\nu(T_h) - \nu_h(T_h))u_h \|_{L^2(K)} \leq \| (\nu(T_h) - \nu_h(T_h))e_u \|_{L^2(K)} + \| (\nu(T_h) - \nu_h(T_h))u \|_{L^2(K)} =: I + II.
\]

The following projection estimate is instrumental.
We first control the term $I$. To accomplish this task, we invoke the fact that $\nu$ is uniformly bounded, i.e., $\nu$ satisfies (5), in combination with estimate (65) to arrive at

$$I \lesssim \|e_u\|_{L^2(K)} + \left[1 + h_K |K|^{-\frac{1}{p}} \left(\|\nabla e_T\|_{L^p(K)} + \|\nabla T\|_{L^p(K)}\right)\right] \|e_u\|_{L^2(K)}$$

$$\lesssim \|e_u\|_{L^2(K)} + h_K^{1 \frac{2}{p}} \left(\|\nabla e_T\|_{L^p(K)} + \|e_u\|_{L^2(K)}\right),$$

where we have also utilized assumption (45), the stability estimate (15), and the fact that $|K| \approx h_K^2$. To estimate $\Pi$, we invoke, again, a triangle inequality to obtain

$$\Pi \leq \|\nu_h(T_h) - \nu_h(T)\|_{L^2(K)} + \|\nu_h(T) - \nu(T)\|_{L^2(K)} + \|\nu(T) - \nu(T_h)\|_{L^2(K)}$$

$$=: \Pi_1 + \Pi_2 + \Pi_3.$$ 

Hölder’s inequality combined with the assumption (46) on $u \in L^p(\Omega)$ yields the estimate

$$\Pi_1 \leq \|\nu_h(T_h) - \nu_h(T)\|_{L^p(K)} \|u\|_{L^{p'}(K)} \lesssim \|\nu_h(T_h) - \nu_h(T)\|_{L^\infty(K)},$$

where $m = 2p/(2 - p)$. This bound, estimate (66), the fact that $|K| \approx h_K^2$, and the stability estimate (15) allow us to conclude that

$$\Pi_1 \lesssim \|\nabla e_T\|_{L^p(K)} + \left(1 + h_K^{1 \frac{2}{p}}\right) \|e_T\|_{L^\infty(K)}.$$ 

To control the terms $\Pi_2$ and $\Pi_3$, we use Hölder’s inequality and the Lipschitz property of $\nu$. These arguments yield

$$\Pi_2 \leq \|\nu_h(T) - \nu(T)\|_{L^\infty(K)} \|u\|_{L^{p'}(K)}, \quad \Pi_3 \leq C\|e_T\|_{L^\infty(K)} \|u\|_{L^{p'}(K)}.$$ 

Consequently, in view of the fact that $u \in L^p(\Omega)$, we obtain

$$\Pi \lesssim \|\nabla e_T\|_{L^p(K)} + \left(1 + h_K^{1 \frac{2}{p}}\right) \|e_T\|_{L^\infty(K)} + \|\nu(T) - \nu(T)\|_{L^\infty(K)}.$$ 

The desired estimate (67) thus follows from replacing the obtained ones for $I$ and $\Pi$ into (68). This concludes the proof.

We now proceed to investigate local estimates for the error indicator $\delta_K$ defined in (42).

**Theorem 17** (local estimate for $\delta_K$). Under the framework of Lemma 16, we have, for $K \in \mathcal{T}_h$, the following local estimate for the error indicator $\delta_K$:

$$\delta_K \lesssim h_K^{\frac{2}{p}} \left(\|e_u\|_{L^2(\mathcal{N}_K)} + \|e_T\|_{L^\infty(\mathcal{N}_K)} + \|\nabla e_T\|_{L^\infty(\mathcal{N}_K)}\right) + \|\nu(T) - \nu(T)\|_{L^\infty(\mathcal{N}_K)},$$

where $\mathcal{N}_K$ is defined in (19) and $\mathcal{P}_K$ denotes the $L^2(K)$–orthogonal projection operator onto $[P_0(K)]^2$. The hidden constant is independent of continuous and discrete solutions $(u, p, T)$ and $(u_h, p_h, T_h)$, respectively, the size of the elements in the mesh $\mathcal{T}_h$, and $\# \mathcal{T}_h$.

**Proof.** We begin the proof by noticing that similar arguments to the ones used
to derive (53) yield, for an arbitrary function \( v \in \mathbf{H}_0^1(\Omega) \), the identity

\[
(70) \quad \int_{\Omega} \nu(T_h) \mathbf{e}_u \cdot v \, dx + \int_{\Omega} (\nu(T) - \nu(T_h)) \mathbf{u} \cdot v \, dx - \int_{\Omega} e_p \, \text{div} \, v \, dx
\]

\[
= \sum_{K \in \mathcal{T}} \left( \int_K (\mathcal{P}_K f - \nu_h(T_h) \mathbf{u}_h - \nabla p_h) \cdot v \, dx + \int_K (f - \mathcal{P}_K f) \cdot v \, dx \right.
\]

\[
- \int_K ((\nu(T_h) - \nu_h(T_h)) \mathbf{u}_h \cdot v \, dx) - \sum_{\gamma \in \mathcal{F}} \int_{\gamma} (\mathcal{J}_\gamma \cdot v) \, ds.
\]

We now proceed in two steps.

Step 1. Let \( K \in \mathcal{T}_h \). We bound the residual term \( h_K \| \mathcal{R}_K \|_{L^2(K)} \) in (42). We begin with an application of a triangle inequality to obtain

\[
(71) \quad h_K \| \mathcal{R}_K \|_{L^2(K)} \leq h_K \| \mathcal{P}_K f - \nu_h(T_h) \mathbf{u}_h - \nabla p_h \|_{L^2(K)}
\]

\[
+ h_K \| (\nu(T_h) - \nu_h(T_h)) \mathbf{u}_h \|_{L^2(K)} + h_K \| f - \mathcal{P}_K f \|_{L^2(K)}.
\]

With the bound (67) at hand, it thus suffices to control the first term on the right-hand side of (71). To accomplish this task, we set \( v = \varphi_K \mathcal{R}_K \) in (70), where \( \mathcal{R}_K = (\mathcal{P}_K f - \nu_h(T_h) \mathbf{u}_h - \nabla p_h)|_K \). Standard properties of the bubble function \( \varphi_K \) combined with basic inequalities and standard inverse estimates [21, Lemma 4.5.3] yield

\[
\| \mathcal{R}_K \|_{L^2(K)} \lesssim \| \mathbf{e}_u \|_{L^2(K)} + \| (\nu(T) - \nu(T_h)) \|_{L^{2p}\gamma(K)} + h_K^{-1} \| e_p \|_{L^2(K)}
\]

\[
+ \| f - \mathcal{P}_K f \|_{L^2(K)} + \| (\nu(T_h) - \nu_h(T_h)) \mathbf{u}_h \|_{L^2(K)}.
\]

We now invoke the Lipschitz property that \( \nu \) satisfies estimate (67), and the fact that \( \mathbf{u} \in \mathbf{L}^{p'}(\Omega) \), to conclude that

\[
(72) \quad h_K \| \mathcal{R}_K \|_{L^2(K)} \lesssim h_K^{\frac{2}{p}} \left( \| \mathbf{e}_u \|_{L^2(K)} + \| e_p \|_{L^{2p}\gamma(K)} + \| \nabla e_T \|_{L^p(K)} \right)
\]

\[
+ \| f - \mathcal{P}_K f \|_{L^2(K)} + h_K \| \nu_h(T) - \nu(T) \|_{L^{2p}\gamma(K)} + h_K \| f - \mathcal{P}_K f \|_{L^2(K)}.
\]

The desired estimate for \( h_K \| \mathcal{R}_K \|_{L^2(K)} \) follows from (71) and (72).

Step 2. Let \( K \in \mathcal{T}_h \) and \( \gamma \in \mathcal{T}_K \). We now bound the term \( h_K \| \mathcal{J}_\gamma \|_{L^2(\gamma)} \) in (42). To accomplish this task, we set \( v = \varphi_\gamma \Pi_\gamma (\mathcal{J}_\gamma) \) in (70), where \( \varphi_\gamma \) denotes the bubble function defined in (54). Standard properties of the bubble function \( \varphi_\gamma \) and inverse estimates allow us to thus obtain the estimate

\[
\| \mathcal{J}_\gamma \|_{L^2(\gamma)}^2 \lesssim \sum_{K' \in \mathcal{N}_\gamma} \left( \| \mathbf{e}_u \|_{L^2(K')} + h_K^{-1} \| e_p \|_{L^2(K')} + \| \mathcal{R}_{K'} \|_{L^2(K')}
\]

\[
+ \| (\nu(T) - \nu(T_h)) \|_{L^{2p}(K')} \| \mathbf{u} \|_{L^{p'}(K')} + \| f - \mathcal{P}_{K'} \mathbf{f} \|_{L^2(K')}
\]

\[
+ \| (\nu(T_h) - \nu_h(T_h)) \mathbf{u}_h \|_{L^2(K')} \| \varphi_\gamma \Pi_\gamma (\mathcal{J}_\gamma) \|_{L^2(K')}
\]

We now invoke the bound \( \| \varphi_\gamma \Pi_\gamma (\mathcal{J}_\gamma) \|_{L^2(K')} \lesssim h_K^{\frac{2}{p}} \| \mathcal{J}_\gamma \|_{L^2(\gamma)} \), the Lipschitz property
that \( \nu \) satisfies, the fact that \( u \in L^p(\Omega) \), and estimates (67) and (72) to arrive at

\[
\begin{align*}
\frac{1}{h_K^2} \| \mathcal{J}_\gamma \|_{L^2(\gamma)} & \lesssim \sum_{K' \in \mathcal{N}_\gamma} \left[ \frac{1}{h_{K'}} \left( \| e_u \|_{L^2(K')} + \| e_T \|_{L^2_p(K')} + \| \nabla e_T \|_{L^p(K')} \right) \\
& + \| e_p \|_{L^2(K')} + h_{K'} \| \nu_h(T) - \nu(T) \|_{L^2_p(K')} + h_{K'} \| f - \mathcal{P}_K f \|_{L^2(K')} \right].
\end{align*}
\]

The desired local estimate (69) thus follows by collecting the bounds (71), (72), and (73). This concludes the proof.

### 5.3.3. Local estimates for \( \mathcal{E}_K \)
We now present local estimates for the local error indicator \( \mathcal{E}_K \) defined in (41).

**Theorem 18** (local estimates for \( \mathcal{E}_K \)). Let \( (u, p, T) \in H_0(\text{div}, \Omega) \times L^2(\Omega) \times W_0^{1,p}(\Omega) \) be a solution of (7) with a forcing term \( f \) which is such that \( \| f \|_{L^2(\Omega)} \leq \nu_\ast \min\{\mathcal{E}, \mathcal{E}_h\} \). Let \( (u_h, p_h, T_h) \in X_h \times Q_h \times V_h \) be a solution to the discrete system (27) for \( 0 < h \leq h_\ast \). If assumptions (45) and (46) hold and, for each \( K \in \mathcal{T}_h \), \( \nu|_K \) is a polynomial, then the local error indicator \( \mathcal{E}_K \) satisfies the local estimate

\[
\begin{align*}
\mathcal{E}_K & \lesssim \| e_u \|_{L^2(\mathcal{N}_K)} + \sum_{K \in \mathcal{N}_K} h_{K'} \| \text{curl} (f - \mathcal{P}_K f) \|_{L^2(\gamma)} \\
& + \| e_T \|_{L^2_p(\mathcal{N}_K)} + \sum_{\gamma \in \mathcal{T}_h} h_{K'}^2 \| (f - \mathcal{P}_K f) \cdot \tau \|_{L^2(\gamma)},
\end{align*}
\]

where \( \mathcal{N}_K \) is defined in (19) and \( \mathcal{P}_K \) denotes the \( L^2(K) \)-orthogonal projection operator onto \( [P_0(K)]^2 \). The hidden constant is independent of continuous and discrete solutions, \( (u, p, T) \) and \( (u_h, p_h, T_h) \), respectively, the size of the elements in the mesh \( \mathcal{T}_h \), and \( \#\mathcal{T}_h \).

**Proof.** Let \( v \in \mathbf{V}(\Omega) \). In view of Lemma 12, we deduce the existence of a unique function \( \vartheta \in H^1_0(\Omega) \) such that \( v = \text{curl} \vartheta \) together with the estimate \( \| \vartheta \|_{H^1(\Omega)} \lesssim \| v \|_{L^2(\Omega)} \). With this setting at hand, we invoke similar arguments to the ones utilized to obtain (50) to arrive at the identity

\[
\begin{align*}
\frac{1}{h_K} \int_\Omega \nu(T_h) e_u \cdot vdx + \int_\Omega (\nu(T) - \nu(T_h)) u \cdot vdx \\
& = \sum_{K \in \mathcal{T}} \left[ \int_K \text{curl}(\mathcal{P}_K f - \nu(T_h) u_h) \vartheta dx + \int_K \text{curl}(f - \mathcal{P}_K f) \vartheta dx \right] \\
& + \sum_{\gamma \in \mathcal{T}_h} \left[ \int_\gamma [(f - \mathcal{P}_K f) \cdot \tau] \vartheta ds + \int_\gamma [(\mathcal{P}_K f - \nu(T_h) u_h) \cdot \tau] \vartheta ds \right].
\end{align*}
\]

We now proceed in two steps.

Step 1. Let \( K \in \mathcal{T}_h \). The goal of this step is to control the residual term \( h_K \| \mathfrak{R}_K \|_{L^2(K)} \) in (41). To accomplish this task, we begin with a simple application of a triangle inequality to obtain

\[
\begin{align*}
h_K \| \mathfrak{R}_K \|_{L^2(K)} & \leq h_K \| \text{curl}(\mathcal{P}_K f - \nu(T_h) u_h) \|_{L^2(K)} + h_K \| \text{curl}(f - \mathcal{P}_K f) \|_{L^2(K)}.
\end{align*}
\]

It thus suffices to control the first term on the right-hand side of the previous expression. To accomplish this task, we define \( \mathfrak{R}_K := \text{curl}(\mathcal{P}_K f - \nu(T_h) u_h) \). We thus
set \( \mathbf{v} = \text{curl}(\mathcal{R}_K \varphi_K) \) and \( \vartheta = \mathcal{R}_K \varphi_K \) in (75), invoke standard inverse estimates, and basic properties of the bubble function \( \varphi_K \) to obtain
\[
\|\mathcal{R}_K\|_{L^2(K)} \lesssim h_K^{-1} \|\nu(T) - \nu(T_h)\|_{L^2(T_h)} \|\mathbf{u}\|_{L^p(K)} + h_K^{-1} \|\mathbf{e}_u\|_{L^2(K)} + \|\text{curl}(\mathbf{f} - \mathcal{P}_K \mathbf{f})\|_{L^2(K)}.
\]
The Lipschitz property that \( \nu \) satisfies combined with assumption (46) thus yield
\[
(77) \quad h_K \|\mathcal{R}_K\|_{L^2(K)} \lesssim \|\mathbf{e}_u\|_{L^2(K)} + \|e_T\|_{L^2(T_h)} + h_K \|\text{curl}(\mathbf{f} - \mathcal{P}_K \mathbf{f})\|_{L^2(K)}.
\]
The desired bound for the residual term thus follows directly from (76) and (77).

**Step 2.** Let \( K \in \mathcal{T}_h \) and \( \gamma \in \mathcal{R}_K \). We define \( \tilde{\gamma}_h \) as \( ((\mathcal{P}_K \mathbf{f} - \nu(T_h) \mathbf{u}_h) \cdot \mathbf{r}) \) and bound \( h_K^\frac{1}{2} \|\tilde{\gamma}_h\|_{L^2(\gamma)} \) in (41). Invoke a triangle inequality to arrive at
\[
(78) \quad h_K^\frac{1}{2} \|\tilde{\gamma}_h\|_{L^2(\gamma)} \leq h_K^\frac{1}{2} \|\tilde{\gamma}_h\|_{L^2(\gamma)} + h_K^\frac{1}{2} \|\mathcal{P}_K \mathbf{f} \cdot \mathbf{r}\|_{L^2(\gamma)}.
\]
In view of (78) it thus suffices to bound the term \( h_K^\frac{1}{2} \|\tilde{\gamma}_h\|_{L^2(\gamma)} \). To accomplish this task, we set \( \tilde{\gamma} = \mathcal{P}_K \mathbf{f} - \nu(T_h) \mathbf{u}_h \) and invoke basic properties of \( \varphi_K \) to arrive at
\[
\|\tilde{\gamma}_h\|_{L^2(\gamma)} \lesssim \sum_{K' \in \mathcal{N}_h} \left( h_K^{-\frac{1}{2}} \|\mathbf{e}_u\|_{L^2(K')} + h_K^{-\frac{1}{2}} \|\nu(T' - \nu(T_h))\|_{L^2(T_h)} \|\mathbf{u}\|_{L^p(K')} \right.
\]
\[
\quad + h_K^{-\frac{1}{2}} \|\text{curl}(\mathbf{f} - \mathcal{P}_K \mathbf{f})\|_{L^2(K')} + h_K^{-\frac{1}{2}} \|\mathcal{R}_K \mathbf{f}\|_{L^2(K')} \right) + \|\mathcal{P}_K \mathbf{f} \cdot \mathbf{r}\|_{L^2(\gamma)},
\]
where we have also used the estimate \( \|\varphi_K \mathcal{P}_K \mathbf{f}\|_{L^2(K')} \lesssim h_K \|\tilde{\gamma}_h\|_{L^2(\gamma)} \). Consequently, the Lipschitz property that \( \nu \) satisfies, estimate (77), and the regularity assumption \( \mathbf{u} \in L^p(\Omega) \) yield
\[
(79) \quad h_K^\frac{1}{2} \|\tilde{\gamma}_h\|_{L^2(\gamma)} \lesssim \sum_{K' \in \mathcal{N}_h} \left( \|\mathbf{e}_u\|_{L^2(K')} + \|e_T\|_{L^2(T_h)} \|\mathbf{u}\|_{L^p(K')} \right.
\]
\[
\quad + h_K^{-\frac{1}{2}} \|\text{curl}(\mathbf{f} - \mathcal{P}_K \mathbf{f})\|_{L^2(K')} + h_K^{-\frac{1}{2}} \|\mathcal{R}_K \mathbf{f}\|_{L^2(K')} \right) + h_K^\frac{1}{2} \|\mathcal{P}_K \mathbf{f} \cdot \mathbf{r}\|_{L^2(\gamma)}.
\]

The combination of the estimates obtained in Steps 1 and 2 concludes the proof.

**6. Numerical experiments.** In this section, we present a series of numerical examples that illustrate the performance of the devised error estimator \( E \) defined in (44). The examples have been carried out with the help of a code that we implemented using C++. All matrices have been assembled exactly and global linear systems were solved using the multifrontal massively parallel sparse direct solver (MUMPS) [11, 12]. The right-hand sides, local indicators, and the error estimator were computed by a quadrature formula which is exact for polynomials of degree 19. To visualize finite element approximations we have used the open source application ParaView [2, 14].

For a given partition \( \mathcal{T}_h \), we solve the discrete system (27), within the discrete setting \( X_h \times Q_h \times V_h \), by using the iterative strategy described in Algorithm 1.
Once a discrete solution is obtained, we compute, for each $K \in \mathcal{T}_h$, the local error indicator $E_K$, defined by

$$E_K := E_{p,K} + E_{K} + \delta_K,$$

(79)

to drive the adaptive procedure described in Algorithm 2. A sequence of adaptively refined meshes is thus generated from the initial meshes shown in Figure 2.

\begin{figure}[h]
\centering
\begin{subfigure}{0.2	extwidth}
\centering
\includegraphics[width=\textwidth]{A.1}
\caption{(A.1)}
\end{subfigure}
\begin{subfigure}{0.2	extwidth}
\centering
\includegraphics[width=\textwidth]{A.2}
\caption{(A.2)}
\end{subfigure}
\caption{The initial meshes used in the adaptive algorithm when the domain $\Omega$ is a square (Example 1) or a two-dimensional L-shaped (Example 2).}
\end{figure}

In the numerical experiments that we perform we go beyond the presented theory and consider a series of Dirac delta sources on the right–hand side of the temperature equation. To be precise, we consider $g = \sum_{z \in D} \delta_z$. Here, $D$ corresponds to a finite ordered subset of $\Omega$ with cardinality $\#D$. Within this setting, we modify the error estimator $E_{p,T}$ associated to the discretization of the heat equation, as follows:

$$E_{p,T} := \left( \sum_{K \in \mathcal{T}} E_{p,K} \right)^{\frac{1}{p}}, \quad p < 2,$$

(80)

where, for each $K \in \mathcal{T}$, the local error indicators $E_{p,K}$ are given now as follows: if $z \in D \cap K$ and $z$ is not a vertex of $K$, then

$$E_{p,K} := \left( \sum_{z \in D \cap K} h_K^{2-2p} + h_K^{p} \| R_K \|_{L^p(K)}^p + h_K^{p} \| J_\gamma \|_{L^p(\partial K \setminus \partial \Omega)}^p \right)^{\frac{1}{p}}.$$

(81)

If $z \in D \cap K$ and $z$ is a vertex of $K$, then

$$E_{p,K} := \left( h_K^{p} \| R_K \|_{L^p(K)}^p + h_K^{p} \| J_\gamma \|_{L^p(\partial K \setminus \partial \Omega)}^p \right)^{\frac{1}{p}}.$$

(82)

If $D \cap K = \emptyset$, then the indicator $E_{p,K}$ is defined as in (82). We notice that the previous modification is not needed if $\#D = 1$; (80) and (38) coincide.

We consider two problems with homogeneous Dirichlet boundary conditions whose exact solutions are not known. We finally mention that, in the numerical experiments that we perform, we violate the assumption that $\nu$ is piecewise polynomial; cf. Theorem 18.

**Example 1:** We let $\Omega = (0,1)^2$, the thermal coefficient $\kappa = 1$, the viscosity function $\nu(s) := \sin(s) + 2$, the external density force $f(x_1, x_2) := (x_1 x_2 (1 - x_1)(1 - x_2), 0)$, and

$$D = \{ (0.25, 0.25), (0.25, 0.75), (0.75, 0.25), (0.75, 0.75) \}.$$

In Figure 3 we report the results obtained for Example 1. We present, for different values of the integrability index $p \in \{1.2, 1.4, 1.6, 1.8\}$, experimental rates of convergence.
we report the results obtained for Example 2. Similar conclusions to the ones presented for Example 1 can be derived. In particular, we observe optimal experimental rates of convergence for all the individual contributions of the total error estimator $E_{\mathcal{F}}$ and for all the values considered for the integrability index $p$ (C.1)–(C.4). We also observe, in subfigure (C.6), that the adaptive refinement is mostly concentrated on the points where the Dirac measures are supported and near to the region of the domain that involves a geometric singularity ($p = 1.6$).

**Algorithm 1 Iterative Scheme**

**Input:** Initial guess $(u_h^0, p_h^0, T_h^0) \in X_h \times Q_h \times V_h$ and tol=10^{-8};

1: For $i \geq 0$, find $(u_h^{i+1}, p_h^{i+1}) \in X_h \times Q_h$ such that

$$
\int_{\Omega} (\nu(T_h^i) u_h^{i+1} \cdot v_h - \rho p_h^{i+1} \text{div} v_h) \, dx = \int_{\Omega} f \cdot v_h \, dx \quad \forall v_h \in X_h,
$$

$$
\int_{\Omega} q_h \, \text{div} u_h^{i+1} \, dx = 0 \quad \forall q_h \in Q_h.
$$

Then, $T_h^{i+1} \in V_h$ is found as the solution to

$$
\int_{\Omega} (\kappa \nabla T_h^{i+1} \cdot \nabla S_h - T_h^{i+1} u_h^{i+1} \cdot \nabla S_h) \, dx = \sum_{z \in D} \langle \delta_z, S_h \rangle \quad \forall S_h \in V_h.
$$

2: If $|((u_h^{i+1}, p_h^{i+1}, T_h^{i+1}) - (u_h^i, p_h^i, T_h^i))| > \text{tol}$, set $i \leftarrow i + 1$ and go to step 1. Here, $| \cdot |$ denotes the Euclidean norm.

**Algorithm 2 Adaptive Algorithm.**

**Input:** Initial mesh $\mathcal{T}_0$, finite subset $\mathcal{D} \subset \Omega$, viscosity coefficient $\nu$, thermal diffusivity $\kappa$, and external source $f$;

1: Solve the discrete problem (27) by using Algorithm 1;

2: For each $K \in \mathcal{T}$ compute the local error indicator $E_K$ defined in (79);

3: Mark an element $K \in \mathcal{T}$ for refinement if:

$$
E_K > \frac{1}{2} \max_{K' \in \mathcal{T}} E_{K'};
$$

4: From step 3, construct a new mesh $\mathcal{T}_{i+1}$, using a longest edge bisection algorithm. Set $i \leftarrow i + 1$ and go to step 1;

for each contribution of the total error estimator, a finite element approximation of the temperature $T_h$, and an adaptively refined mesh. We observe in subfigures (B.1)–(B.4), that our devised AFEM delivers optimal experimental rates of convergence for all the contributions of the total error estimator $E_{\mathcal{F}}$ and for all the values considered for the integrability index $p$. We also observe, in the adaptively refined mesh (B.6), that the adaptive refinement is mostly concentrated on the points where the Dirac measures are supported ($p = 1.6$).

**Example 2:** We let $\Omega = (-1,1)^2 \setminus [0,1) \times [-1,0)$, the thermal coefficient $\kappa = 1$, the viscosity function $\nu(s) := e^{-s^2} + 1$, the external force $f(x_1, x_2) := (10x_2(1 - x_1)(1 + x_1), 5x_1(1 - x_2)(1 + x_1))$, and $\mathcal{D} = \{(-0.5, -0.5), (-0.5, 0.5), (0.5, 0.5)\}$.

In Figure 4 we report the results obtained for Example 2. Similar conclusions to the ones presented for Example 1 can be derived. In particular, we observe optimal experimental rates of convergence for all the individual contributions of the total error estimator $E_{\mathcal{F}}$ and for all the values considered for the integrability index $p$ (C.1)–(C.4). We also observe, in subfigure (C.6), that the adaptive refinement is mostly concentrated on the points where the Dirac measures are supported and near to the region of the domain that involves a geometric singularity ($p = 1.6$).
Estimator $\varepsilon_{p,T}$

Estimator $\mathcal{E}_T$

Estimator $\mathcal{E}_p$

Estimator $\mathcal{E}_f$

Fig. 3. Ex. 1: Experimental rates of convergence for the error estimators $\varepsilon_{p,T}$ (B.1), $\mathcal{E}_T$ (B.2), $\mathcal{E}_p$ (B.3), and $\mathcal{E}_f$ (B.4), for $p \in \{1.2, 1.4, 1.6, 1.8\}$, a finite element approximation of the temperature $T_h$ (B.5), and the mesh obtained after 29 iterations of the adaptive loop for $p = 1.6$ (B.6).
