RANDOM CUTOUT SETS WITH SPATIALLY INHOMOGENEOUS INTENSITIES

TUOMO OJALA, VILLE SUOMALA, AND MENG WU

Abstract. We study the Hausdorff dimension of Poissonian cutout sets defined via inhomogeneous intensity measures on $Q$-regular metric spaces. We obtain formulas for the Hausdorff dimension of such cutouts in self-similar and self-conformal spaces using the multifractal decomposition of the average densities for the natural measures.

1. Introduction

Given a metric space $X$ and a sequence of open balls $B(x_n, r_n) \subset X$, we define the cutout set corresponding to the sequence $(x_n, r_n) \in X \times (0, 1)$ as

$$ E = X \setminus \bigcup_n B(x_n, r_n). $$

That is, $E$ is the set left uncovered by the union of the balls $B(x_n, r_n)$. If the centres of these cutouts are dynamically defined (e.g. if $x_{n+1} = T(x_n)$ for a given dynamics $T : X \to X$) or if $x_n$ are randomly distributed, it is of interest to investigate whether $E \neq \emptyset$ and to determine its structure and size such as Hausdorff dimension. This problem arises from Diophantine approximation and versions of the Dvoretzky covering problem as well as in the study of renewal sets (see e.g. [19, 15, 17]). In this paper, we consider only the case in which the $x_n$ are random variables. We refer to [9, 18] for recent accounts and further references in the dynamical setting (see also [14]).

We shall next describe our model in detail. Let $X = (X, \mathcal{H}, d)$ be a bounded metric space endowed with a measure $\mathcal{H}$, which is (Ahlfors-David) $Q$-regular for some $0 < Q < \infty$: there are constants $0 < c_0 < C_0 < \infty$ such that

$$ c_0 r^Q \leq \mathcal{H}(B(x, r)) \leq C_0 r^Q, $$

for all $x \in X$, $0 < r < \text{diam}(X)$. (Throughout the paper, a measure will refer to a locally finite Borel regular outer measure.)

2010 Mathematics Subject Classification. Primary 60D05; Secondary 28A80, 37D35, 37C45.
For each $0 < \gamma < +\infty$, let $\mathcal{Y}$ be a Poisson point process on $X \times (0,1)$ with intensity $\gamma \mathcal{H} \times \rho$, where $\rho$ is the measure defined by $\rho(dr) = \frac{dr}{r^{d+1}}$ on $(0,1)$. Thus, $\mathcal{Y}$ is a random collection of pairs $(x, r) \in X \times (0,1)$ such that

1. For each Borel set $A \subset X \times (0,1)$, the random variable $\sharp(A \cap \mathcal{Y})$ is Poisson distributed with mean $\gamma \mathcal{H} \times \rho(A)$.
2. For disjoint $A_i$, the random variables $\sharp(A_i \cap \mathcal{Y})$ are independent.

In particular, $\mathcal{Y}$ is a.s. countably infinite. We consider the random cutout set:

$$E = X \setminus \bigcup_{(x,r) \in \mathcal{Y}} B(x,r).$$

Note that the intensity of $\mathcal{Y}$ and the induced probability $\mathbb{P}$ crucially depend on $\gamma$. Let

$$\gamma_0 := \sup\{\gamma > 0 : \mathbb{P}(E \neq \emptyset) > 0\}.$$

A central problem is to determine the exact value of $\gamma_0$ ($0 < \gamma_0 < \infty$ always holds, see Remark 2.5). Further, when $0 < \gamma < \gamma_0$, we would like to determine the a.s. Hausdorff dimension of $E$. Since for any $\gamma > 0$, there is a positive probability for extinction ($E = \emptyset$), we follow [30] and define the essential dimension of the random set $E$ as $\mathbb{P} - \text{esssup} \dim_H(E)$. This is the unique value $s \geq 0$ such that $\dim_H(E) \leq s$ a.s. and for all $t < s$, there is a positive probability that $\dim_H(E) > t$.

The case when $X$ is a subdomain of some Euclidean space $\mathbb{R}^d$ and $\mathcal{H} = \mathcal{L}^d$ is the $d$-dimensional Lebesgue measure is well understood. In particular, $\gamma_0 = \gamma_0(d) = d/\alpha(d)$, where $\alpha(d) = \mathcal{L}^d(B(0,1))$ and for $0 < \gamma \leq d/\alpha(d)$, the essential Hausdorff dimension (and also the box-dimension) equals $d - \gamma \alpha(d)$, see [5, 30, 27, 20, 26]. In this case, the point process $\mathcal{Y}$ is translation invariant in an obvious way, but it possesses also strong scale invariance: If $I, \lambda I \subset (0,1)$ for $\lambda > 0$, then it is equally likely that a point $x \in X$ is covered by a ball $B(x_n, r_n) \in \mathcal{Y}$ for $r_n \in I$ as it is for $r_n \in \lambda I$. There are many works (e.g. [19, 11, 30, 24, 4]) in which this condition has been relaxed by replacing the measure $\rho(dr)$ by a more general measure of the form $\frac{dr}{h(r)}$. For such generalizations, it is still possible to get results on the size of $E$ and the range of $\gamma$, for which $E \neq \emptyset$ with positive probability. However, it turns out that the model is much more sensitive for the changes in the spatial component $\mathcal{H}$ and in essentially all the works we are aware of, only the case in which $\mathcal{H} = \mathcal{L}$ has been considered. The papers [12] and [30] are notable exceptions. In these papers, various estimates for the dimension of the cutout sets are obtained in the context of a general metric space. However, when it comes to determining the value of the essential dimension, it is assumed in [30] that $\mathcal{H} = \mathcal{L}$ and also in [12], there is a strong homogeneity assumption on $\mathcal{H}$ (implying in particular that $\sup_{x,y \in X} \frac{\mathcal{H}(B(x,r))}{\mathcal{H}(B(y,r))} \to 1$ as $r \to 0$).
We note that in many of the references given above, the model is actually a one where $r_n$ is a deterministic sequence and $x_n$ are independent and uniformly distributed. However, in the case of translation invariant intensity the methods in the case of deterministic radii and iid centres are essentially the same as in the Poissonian case described above. Further, in many of the cited works, a significant part of attention has been given to the study of the random covering set

$$F = \bigcap_{k \in \mathbb{N}} \bigcup_{n \geq k} B(x_n, r_n),$$

consisting of the points covered infinitely often by the balls $B(x_n, r_n)$. However, under the present assumptions and for any choice of $\gamma$, it follows from Fubini’s theorem that a.s. $\mathcal{H}(X \setminus F) = 0$ so that the dimensional properties of $F$ are uninteresting. Further, for the case of deterministic radii, as well as for more general Poissonian intensities $\mathcal{H}(dx) \times \frac{dr}{h(r)}$, the dimensional properties of the associated random covering set in the setting of $Q$-regular spaces are analogous to the Euclidean situation (where $\mathcal{H}$ is the Lebesgue measure). For instance, the proof of [13, Proposition 4.7] adapts easily to the case of $Q$-regular metric spaces. These observations indicate that changing the spatial component of the intensity measure does not affect the fractal properties of the random covering sets, as opposed to the “dual problem” of determining the dimension of the cutout set $E$.

Before going further, let us provide a simple example to get an idea why the lack of homogeneity in $\mathcal{H}$ is a subtle issue for the cutouts. Suppose $X = X_1 \cup X_2$ where, say, $X_1$ and $X_2$ are disjoint subintervals of $[0, 1]$. Let $\mu = a\mathcal{L}_{X_1} + b\mathcal{L}_{X_2}$ and suppose $0 < a < b < \frac{1}{2}$. Now, conditional on $E \cap X_1 = \emptyset$, we know from the above discussion that a.s. $\dim_H(E) \leq 1 - 2b$ while on $E \cap X_1 \neq \emptyset$, there is a positive probability that $\dim_H(E) = 1 - 2a$. This shows that one cannot expect any a.s. constancy result for the Hausdorff dimension of $E$. Of course, it still holds that the essential dimension is $1 - 2a$ (see also Remark [34]).

For each $0 < t < 1$, let $E_t = X \setminus \bigcup_{(x,r) \in Y, r > t} B(x, r)$ and for $x \in X$ denote

$$p(x, t) = \mathbb{P}(x \in E_t) = \exp \left( -\gamma \int_{r=t}^{1} \mathcal{H}(B(x, r))r^{-Q-1} \, dr \right).$$

This formula suggests an intimate connection to the lower and upper $(Q)$-average densities of $\mathcal{H}$ defined at $x \in X$ as

$$\underline{\Lambda}(\mathcal{H}, x) = \liminf_{t \to 0} \Lambda(\mathcal{H}, x, t), \quad (1.1)$$

$$\bar{\Lambda}(\mathcal{H}, x) = \limsup_{t \to 0} \Lambda(\mathcal{H}, x, t), \quad (1.2)$$
where
\[
A(\mathcal{H}, x, t) = \int_{r=t}^{t} \mathcal{H}(B(x, r)) r^{-Q-1} dr - \log t.
\]

If \(A(\mathcal{H}, x)\) and \(\overline{A}(\mathcal{H}, x)\) coincide, we denote the common value by \(A(\mathcal{H}, x)\). Observe that
\[
p(x, t) = t^{\gamma A(\mathcal{H}, x, t)},
\]
so that the expected measure of \(E_t\) equals
\[
\mathbb{E}(\mathcal{H}(E_t)) = \int_{x \in X} t^{\gamma A(\mathcal{H}, x, t)} d\mathcal{H}(x).
\]

It is well known that for fractal \(\mathcal{H}\), the density \(\lim_{r \to 0} \frac{\mathcal{H}(B(x, r))}{r^Q}\) fails to exist at \(\mathcal{H}\)-almost all points. However, for many important \(Q\)-regular measures (see [3, 6, 7, 28, 29]), the average density \(A(\mathcal{H}, x)\) is known to exist and take a constant value \(\alpha\) at \(\mathcal{H}\)-almost all points of \(X = \text{supp} \mathcal{H}\). Recalling (1.4), a first naive guess would be to predict that in such a case the essential dimension of the random set \(E\) would equal \(Q - \gamma \alpha\). However, it turns out that in most cases of interest, the dimension of \(E\) is affected by the zero measure set, where \(A(\mathcal{H}, x) \neq \alpha\) and a finer analysis of the multifractal properties of the average densities is needed in order to catch the correct dimension of the cutout set \(E\).

The structure of the paper is as follows. In Section 2 using the familiar first and second moment methods, we present some tools to estimate the dimension of the intersections of \(E\) with certain sub- and superlevel sets of the average densities \(\overline{A}(\mathcal{H}, \cdot), A(\mathcal{H}, \cdot)\). This part applies to any \(Q\)-regular measure and can be used directly to obtain some (coarse) estimates on the value of \(\gamma_0\) and on the essential dimension of \(E\). In Section 3 we present the main result of the paper; We consider the case when \(X\) is self-similar, or more generally self-conformal, and satisfies the strong separation condition. Using tools from thermodynamical formalism and expressing the average densities as ergodic averages, we examine their multifractal spectrum. This enables us to obtain a formula for \(\gamma_0\) and for the essential dimension of \(E\) when \(0 < \gamma < \gamma_0\).

2. Auxiliary dimension estimates

In this section, we provide some useful upper and lower estimates for the Hausdorff dimension of \(E \cap \{ \alpha < A(\mathcal{H}, x) < \beta\} \) when \(\alpha\) and \(\beta\) vary. Our standing assumption is that \(\mathcal{H}\) is a \(Q\)-regular measure on the metric space \(X\). Further, the parameter \(\gamma > 0\) that determines (together with \(\mathcal{H}\)) the intensity of \(Y\) is fixed throughout the section. For \(F \subset X\) and \(t > 0\), we denote by \(F(t) = \{ y \in X : d(y, F) \leq t \}\), the closed \(t\)-neighbourhood of the set \(F\).
2.1. **Dimension upper bound.** For each $0 < \alpha < \beta < \infty$ and $0 < r < 1$, we denote

$$X(\alpha, \beta, r) = \{ x \in X \mid \alpha < A(H, x, r) < \beta \}.$$  

**Lemma 2.1.** (i) There exists $C < \infty$, independent of $t$, such that

$$\mathbb{P}(x \in E(t)) \leq C \mathbb{P}(x \in E_t).$$

(ii) If $0 \leq \alpha' < \alpha < \beta < \beta' < \infty$, there exists $r_0 > 0$ such that

$$X(\alpha, \beta, r) \subset X(\alpha', \beta', r)$$

for all $0 < r < r_0$.

**Proof.** (i) Observe that by definition of $E(t)$ and elementary geometry, we have

$$E(t) \subset X \setminus \bigcup_{(x,r) \in \mathcal{Y}, r>t} B(x, r - t) =: E_t'.$$

So $\mathbb{P}(x \in E(t)) \leq \mathbb{P}(x \in E_t')$. Thus, we only need to show that $\mathbb{P}(x \in E_t') \leq C \mathbb{P}(x \in E_t)$ for some $C < \infty$ independent of $t$. Since $x \in E_t'$ if and only if $A \cap \mathcal{Y} = \emptyset$ for

$$A = \{(y,r) : r > t, y \in B(x, r - t)\},$$

we deduce that

$$\mathbb{P}(x \in E_t') \leq \exp \left( -\gamma \int_1^t H(B(x, r - t)) \frac{dr}{r^{Q+1}} \right). \tag{2.1}$$

Now, we have

$$\int_t^1 H(B(x, r - t)) \frac{dr}{r^{Q+1}} \geq \int_{2t}^1 H(B(x, r - t)) \frac{dr}{r^{Q+1}} = \int_t^1 H(B(x, r)) \frac{dr}{r^{Q+1}(1 + t/r)^{Q+1}}. \tag{2.2}$$

An elementary calculation shows that

$$\frac{1}{(1 + y)^{Q+1}} \geq 1 - (Q + 1)y \text{ for all } y \in [0, 1].$$

Applying this to $y = t/r$ in (2.2), we get

$$\int_t^1 H(B(x, r - t)) \frac{dr}{r^{Q+1}} \geq \int_t^1 H(B(x, r)) \frac{dr}{r^{Q+1}} - (Q + 1)t \int_t^1 H(B(x, r)) \frac{dr}{r^{Q+2}}.$$

Since $C' = \sup_{0 < t \leq 1} (Q + 1) t \int_t^1 H(B(x, r)) \frac{dr}{r^{Q+2}} < +\infty$, substituting the above inequality in (2.1) yields

$$\mathbb{P}(x \in E_t') \leq \mathbb{P}(x \in E_t) \exp(\gamma C').$$

Letting $C = \exp(\gamma C')$ ends the proof of (i).
(ii) We have seen in the proof of (i) that there exists $C < +\infty$, independent of $t$, such that
\[\int_t^1 H(B(x, r) \setminus B(x, r - t)) \frac{dr}{r^{Q+1}} \leq C.\]
By the same argument, it follows that
\[\int_t^1 H(B(x, r + t) \setminus B(x, r - t)) \frac{dr}{r^{Q+1}} \leq C'\]
for some $C' < +\infty$ independent of $t$. Thus for every $\varepsilon > 0$ there exists $r_0 > 0$ such that
\[\int_t^1 H(B(x, r + t) \setminus B(x, r - t)) \frac{dr}{r^{Q+1}} \leq \varepsilon \]
for every $0 < t < r_0$. Since for every $x \in X(\alpha, \beta, t)(t)$, there exists $y \in X(\alpha, \beta, t)$ such that $d(x, y) < t$, we deduce that
\[D(H, x, t) \leq D(H, y, t) + \int_t^1 H(B(x, r + t) \setminus B(x, r - t)) \frac{dr}{-\log t} < \beta',\]
when $\varepsilon < \beta' - \beta$. The lower bound follows by a similar calculation. □

**Lemma 2.2.** Let $0 < \alpha' < \alpha < \beta < \beta' < \infty$ and $C, \eta \geq 0$. Suppose that $H(X(\alpha', \beta', r)) \leq Cr^\eta$ for all $0 < r < 1$. Then a.s.
\[\dim_H \left( E \cap \limsup_{r \downarrow 0} X(\alpha, \beta, r) \right) \leq Q - \gamma \alpha' - \eta,\]
if $Q - \gamma \alpha' - \eta \geq 0$ while $E \cap \limsup_{r \downarrow 0} X(\alpha, \beta, r) = \emptyset$ if $Q - \gamma \alpha' - \eta < 0$.

**Proof.** Observe that by (1.3), $P(x \in E_r) \leq r^{-\alpha'}$, for $x \in X(\alpha', \beta', r)$. Pick $\alpha' \leq \widetilde{\alpha} < \alpha$, $\beta < \widetilde{\beta} < \beta'$. Using Lemma 2.1 we have for each $\theta < \gamma \alpha' + \eta$ that
\[E \left( \sum_{n \in \mathbb{N}} 2^{\theta n} H \left( \left( X(\widetilde{\alpha}, \widetilde{\beta}, 2^{-n}) \cap E \right) (2^{-n}) \right) \right) \leq C_1 \sum_n 2^{\theta n} \int_{X(\alpha', \beta', 2^{-n})} P(x \in E_{2^{-n}}) dH(x) \leq C_1 \sum_n 2^{n} H(X(\alpha', \beta', 2^{-n})) 2^{-n \gamma \alpha'} \leq C_2 \sum_n 2^{n (\theta - \gamma \alpha' - \eta)} < \infty.\]
In particular, we see that almost surely,
\[\lim_{n \to \infty} 2^{n} H \left( \left( X(\widetilde{\alpha}, \widetilde{\beta}, 2^{-n}) \cap E \right) (2^{-n}) \right) = 0.\]
Since $\mathcal{H}$ is $Q$-regular this implies a.s the existence of $N_0 \in \mathbb{N}$ such that for all $n \geq N_0$, the set $(X(\tilde{\alpha}, \tilde{\beta}, 2^{-n}) \cap E)$ is covered by a union of balls

$$B(x_{n,1}, 2^{-n}), \ldots, B(x_{n,m_n}, 2^{-n})$$

with $m_n \leq 2^{n(Q-\theta)}$. Since

$$\limsup_{r \downarrow 0} X(\alpha, \beta, r) \subset \bigcup_{n=N_0}^{\infty} \bigcup_{i=1}^{m_n} B(x_{n,i}, 2^{-n}),$$

for all $N \geq N_0$, and

$$\sum_{n \geq N} m_n 2^{-n(Q-\theta+\varepsilon)} \leq \sum_{n \geq N} 2^{-n(\varepsilon-\theta)} \rightarrow 0,$$

for any $\varepsilon > 0$, this implies the claim. Note that if $Q - \gamma \alpha' < 0$, we have $m_n = 0$ and thus $(X(\tilde{\alpha}, \tilde{\beta}, 2^{-n}) \cap E)(2^{-n}) = \emptyset$ for all $n \geq N_0$. \hfill $\square$

2.2. A lower estimate. Let $\mu$ be a measure on $X$. For each $t > 0$, we define a measure $\nu_t$ by

$$d\nu_t(x) = p(x,t)^{-1} \mathbf{1}_{E_1}(x) \, d\mu(x). \tag{2.3}$$

Then $(\nu_t)_{t>0}$ is a $T$-martingale in the sense of Kahane [16] and it is easy to check that a.s $\nu_t$ is weakly convergent to a random limit measure $\nu$.

Let $0 < s < \infty$ be such that

$$\int_X \int_X d(x,y)^{-s} \, d\mu(x) \, d\mu(y) < \infty, \tag{2.4}$$

and define a Kernel $K : X \times X \rightarrow [0, \infty]$ by

$$K(x,y) = d(x,y)^{-s} \mathbb{P}(x \in E_{d(x,y)}). \tag{2.5}$$

Lemma 2.3.

$$\mathbb{E} \left( \int \int K(x,y) \, d\nu(x) \, d\nu(y) \right) < \infty.$$

Proof. It suffices to show that for all $0 < t < 1$,

$$\mathbb{E} \left( \int \int K(x,y) \, d\nu_t(x) \, d\nu_t(y) \right) < C < \infty, \tag{2.6}$$

where $C$ is independent of $t$. Indeed, using that $x \mapsto A(\mathcal{H}, x, r)$ is continuous (this follows e.g. from the calculation in the proof of Lemma 2.1) and recalling (1.3) allows to express $K(x,y)$ as a limit of increasing continuous functions, so that (2.6) yields the claim.

We first claim that for all $0 < \delta < 1$,

$$\mathbb{P}(x,y \in E_\delta) \leq C \mathbb{P}(x \in E_\delta) \mathbb{P}(y \in E_\delta) / \mathbb{P}(x \in E_{d(x,y)}), \tag{2.7}$$
where $C$ is independent of $\delta$, $d(x, y)$. Indeed, this is a result of direct calculation (we assume that $\delta < d(x, y)/2$ as otherwise (2.7) follows directly from (1.3)):

$$
\int_{\delta}^{1} \mathcal{H}(B(x, s) \cup B(y, s)) s^{-Q-1} ds \\
\geq \int_{\delta}^{1} \mathcal{H}(B(y, s)) s^{-Q-1} ds + \int_{\delta}^{d(x, y)/2} \mathcal{H}(B(x, s)) s^{-Q-1} ds \\
\geq \int_{\delta}^{1} \mathcal{H}(B(y, s)) s^{-Q-1} ds + \int_{\delta}^{1} \mathcal{H}(B(x, s)) s^{-Q-1} ds \\
- \int_{d(x, y)/2}^{1} \mathcal{H}(B(x, s)) s^{-Q-1} ds - C_1,
$$

where $C_1$ is a constant such that $\int_{d(x, y)/2}^{d(x, y)} \mathcal{H}(B(x, s)) s^{-Q-1} ds \leq C_1$ and thus only depends on the $Q$-regularity data of the measure $\mathcal{H}$. The claim (2.7) now follows by multiplying the inequality by $-\gamma$ and taking the exponential.

Combining (2.7), Fubini’s theorem, and (2.4) we calculate,

$$
\mathbb{E} \left( \int \int K(x, y) d\nu_t(x) d\nu_t(y) \right) \\
= \int_X \int_X \frac{\mathbb{P}(x, y \in E_t) \mathbb{P}(x \in E_{d(x, y)}, d(x, y) < s)}{\mathbb{P}(x \in E_t) \mathbb{P}(y \in E_t)} d\mu(x) d\mu(y) \\
\leq C \int \int d(x, y)^{-s} d\mu(x) d\mu(y) < \infty.
$$

Since this upper bound is independent of $t$, we are done. \qed

The following lemma employs the standard connection between capacity and dimension in the situation at hand. Recall that the lower local dimension of a measure $\nu$ at $x \in X$ is defined as

$$
\dim_{\text{loc}}(\nu, x) = \liminf_{r \downarrow 0} \frac{\log \nu(B(x, r))}{\log r}.
$$

**Lemma 2.4.** Suppose that $s - \gamma \alpha > 0$. If for $\mu$-almost all $x \in X$, $\overline{\mathcal{A}}(\mathcal{H}, x) < \alpha$, then $\nu(X) > 0$ with positive probability and almost surely,

$$
\dim_{\text{loc}}(\nu, x) \geq s - \gamma \alpha,
$$

for $\nu$-almost all $x \in X$.  

Proof. We first observe that if \( N \subset X \) is \( \mu \)-null, then it is almost surely \( \nu \)-null. Indeed, for each \( \varepsilon > 0 \), there is an open set \( U_\varepsilon \supset N \), such that \( \mu(U_\varepsilon) < \varepsilon \). Thus Fatou’s lemma gives
\[
\mathbb{E}(\nu(N)) \leq \mathbb{E}(\nu(U_\varepsilon)) \leq \mathbb{E}(\liminf_{t \downarrow 0} \nu_t(U_\varepsilon)) \leq \liminf_{t \downarrow 0} \mathbb{E} \nu_t(U_\varepsilon) = \mu(U_\varepsilon) < \varepsilon.
\]
Whence \( \mathbb{E}(\nu(N)) = 0 \), or in other words, \( \nu(N) = 0 \) almost surely.

Let
\[
F_M = \{ x \in X \mid \overline{\mathcal{A}}(\mathcal{H}, x) < \alpha \text{ and } \int_{y \in X} K(x, y) \, d\nu < M \}.
\]
Then, by the above and Lemma 2.3, it follows that a.s.
\[
\nu(X \setminus F_M) \to 0 \text{ as } M \to \infty.
\]
On the other hand, for all \( x \in F_M \), and all small enough \( 0 < r < 1 \), \ref{equation:2.5} and \ref{equation:1.3} give \( K(x, y) \geq \text{dist}(x, y)^{\gamma_0-s} \geq r^{\gamma_0-s} \) for \( y \in B(x, r) \) and whence
\[
r^{\gamma_0-s} \nu(B(x, r)) \leq \int_{y \in B(x, r)} K(x, y) \, d\nu < M,
\]
implying \( \nu(B(x, r)) \leq Mr^{s-\gamma_0} \). The second claim of the Lemma now follows by taking logarithms, letting \( r \downarrow 0 \) and finally letting \( M \to \infty \).

To prove that \( \nu(X) > 0 \) is an event of positive probability, we first pick so small \( r_0 > 0 \) that \( \mu(F) > 0 \), where \( F = \{ x \in X \mid \mathcal{A}(\mathcal{H}, x) < \alpha \} \) for all \( 0 < r < r_0 \). Calculating as in the proof of Lemma 2.3 yields
\[
\mathbb{E}(\nu_t(F)^2) \leq C \int_{x \in F} \int_{y \in F} d(x, y)^{-\gamma \mathcal{A}(\mathcal{H}, x, d(x, y))} \, d\mu(x) \, d\mu(y)
\]
\[
\leq C \int \int d(x, y)^{-s} \, d\mu(x) \, d\mu(y) < \infty.
\]
In other words, \( \nu_t(F) \) is an \( L^2 \)-bounded martingale with nonzero expectation (since \( \mu(F) > 0 \)). Whence, \( \nu(X) \geq \nu(F) > 0 \) with positive probability. \( \square \)

Remarks 2.5. (i) Lemmas 2.2 and 2.4 can be used directly to obtain upper and lower estimates on \( \gamma_0 \) and on the dimension of \( E \). Let \( d_0 = \inf_{x \in X} \mathcal{A}(\mathcal{H}, x) \), \( D_0 = \sup_{x \in X} \overline{\mathcal{A}}(\mathcal{H}, x) \) (note that \( c_0 \leq d_0 \leq D_0 \leq C_0 \)). Applying Lemma 2.2 with \( \eta = 0 \), implies \( \gamma_0 \leq Q/d_0 \) and \( \dim_B(E) \leq Q - \gamma d_0 \) a.s., if \( 0 < \gamma \leq \gamma_0 \). In turn, Lemma 2.4 applied for \( \mu = \mathcal{H} \) and \( s = Q \), gives the estimate \( \gamma_0 \geq Q/D_0 \) and provided \( 0 < \gamma < Q/D_0 \), implies that \( \dim_H(E) \geq Q - \gamma D_0 \) with positive probability.

(ii) As will be seen in Proposition 2.7 below, even if \( \mathcal{A}(\mathcal{H}, x) = \overline{\mathcal{A}}(\mathcal{H}, x) = \alpha \) for \( \mathcal{H} \)-almost every \( x \), these estimates are usually far from being sharp. Actually, as will be seen in the Section 3, the dimension of \( E \) depends intimately on the multifractal properties of the average density of \( \mathcal{H} \).
(iii) As of curiosity, we mention that if $X = \mathbb{T}^d$ is the $d$-dimensional torus and $Q = d$, then $\gamma_0 = d/d_0$ and for $\gamma \leq \gamma_0$, the essential dimension is $d - \gamma d_0$. Indeed, for each $c > d_0$, there is a point $x \in \mathbb{T}^d$ and $r > 0$ such that $\mathcal{H}(B(x, r)) \leq cr^d$.

An application of the Lebesgue density theorem yields a Borel set $\{ \} = \emptyset$ for each $\gamma > d_0$. By Frostman’s lemma, for each $\alpha > 0$, denote $X(\alpha) = \{ x \in X : \mathcal{H}(x, x, r) = \alpha \}$. Let $\alpha_{\min} = \inf\{ \alpha : X(\alpha) \neq \emptyset \}$, $\alpha_{\max} = \sup\{ \alpha : X(\alpha) \neq \emptyset \}$. Further, let

$$f(\alpha) = \dim_{\mathcal{H}}(X(\alpha)).$$

Note that $f$ obtains its maximum at some $\alpha_{\min} \leq \gamma_0 \leq \alpha_{\max}$ and $f(\alpha_0) = Q$. By Frostman’s lemma, for each $\alpha_{\min} < \alpha < \alpha_{\max}$ with $X(\alpha) \neq \emptyset$, there exists a probability measure $\mu_\alpha$ on $X$ such that $\mu_\alpha(X(\alpha)) = 1$ and further

$$\int \int d(x, y)^{\varepsilon - f(\alpha)} d\mu_\alpha(x) d\mu_\alpha(y) < C < \infty \quad (2.8)$$

for all $\varepsilon > 0$.

Let

$$m(\gamma) = \sup_{\alpha_{\min} \leq \alpha \leq \alpha_{\max}} f(\alpha) - \gamma \alpha.$$ 

The following proposition is a consequence of Lemmas 2.2 and 2.4, which says that if $f(\alpha)$ is continuous on $(\alpha_{\min}, \alpha_{\max})$ and the quantity $D(\mathcal{H}, x, r)$ satisfies a large deviation principle then the dimension of $E$ is given by $m(\gamma)$.

**Proposition 2.6.** Suppose that $f(\alpha)$ is continuous on $(\alpha_{\min}, \alpha_{\max})$ and

$$\mathcal{H}(X(\alpha, \beta, r)) = O(r^{Q - f(\beta) - \varepsilon}) \quad (2.9)$$

for all $0 < \alpha < \beta \leq \alpha_0$ and all $\varepsilon > 0$. If $m \geq 0$, then almost surely $\dim_{\mathcal{H}}(E) \leq m$ and $\dim_{\mathcal{H}}(E) \geq m$ with positive probability. If $m < 0$, then $E = \emptyset$ almost surely.

**Proof.** Suppose that $m \geq 0$. We first consider the upper bound. Since trivially $\mathbb{E}(\mathcal{H}(X(\alpha_0, +\infty, r)) \leq \mathcal{H}(X) = C < \infty$, Lemma 2.2 implies that almost surely,

$$\dim_{\mathcal{H}}(E \cap \{ x \mid \overline{\mathcal{H}}(x) \geq \alpha_0 \}) \leq \max\{ 0, Q - \gamma \alpha_0 \} = \max\{ 0, f(\alpha_0) - \gamma \alpha_0 \} \leq m.$$

Next, let $0 < \alpha < \beta < \alpha_0$. Combining Lemma 2.2 and (2.9), gives for all small $\varepsilon > 0$ that

$$\dim_{\mathcal{H}}(E \cap \{ x \mid \alpha \leq \overline{\mathcal{H}}(x) \leq \beta \}) \leq \max\{ 0, f(\beta + \varepsilon) - \gamma \alpha + \varepsilon \}.$$ 

Letting $\varepsilon \downarrow 0$ and using the continuity of $f$ on $[\alpha_{\min}, \alpha_{\max}]$ implies

$$\dim_{\mathcal{H}}\left( E \cap \{ x \mid \alpha \leq \overline{\mathcal{H}}(x) \leq \alpha + \frac{1}{n} \} \right) \leq \max\{ 0, f \left( \alpha + \frac{1}{n} \right) - \gamma \alpha \}.$$
for each $\alpha_{\min} \leq \alpha = k/n < \alpha_{\max}$, $k \in \mathbb{N}$. Since there are only finitely many such values of $\alpha$, we get
\[
\dim_H \left( E \cap \{ x \mid A(H, x) \leq \alpha_0 \} \right) \leq \max_{k \in \mathbb{N}, \alpha_{\min} \leq \frac{k}{n} \leq \alpha_0} f \left( \frac{k+1}{n} \right) - \frac{\gamma k}{n} \tag{2.10}
\]
Letting $n \to \infty$ and using the (uniform) continuity of $f$ on $]\alpha_{\min}, \alpha_{\max}[$ once more, finally yields the almost sure upper bound
\[
\dim_H(E) \leq m.
\]
If $m < 0$, a straightforward modification of the argument using the latter claim of Lemma 2.2 implies $E = \emptyset$ almost surely.

To prove the lower bound, we pick $\alpha$ such that
\[
m = \max_{\alpha_{\min} \leq \alpha \leq \alpha_0} f(\alpha) - \gamma \alpha > 0
\]
and consider the measure $\mu_{\alpha}$ provided by Frostman’s Lemma as in (2.8). Consider $\nu_t$ as in (2.3) and $\nu$ such that $\nu_t \to \nu$. Lemma 2.4 implies that with positive probability $\nu(X) > 0$ and further (applying the lemma with $\alpha + \varepsilon$ and letting $\varepsilon \downarrow 0$) a.s.
\[
\dim_{\text{loc}}(\nu, x) \geq m,
\]
for $\nu$-almost all $x \in X$. Since $\text{supp}(\nu) \subset E$, this shows in particular that $\dim_H(E) \geq m$ with positive probability. \hfill \Box

**Remark 2.7.** The method presented above works for more general gauge functions $h : (0, 1) \to (0, +\infty)$ and measures $H$ so that $C^{-1} < H(B(x,r))/h(r) < C$ for some $C < \infty$. In this case the Poisson intensity is $\gamma H(dx) \times \frac{dr}{h(r)}$. In the above, we have considered the case $h(r) = r^Q$, for simplicity of notation and because the self-conformal measures in Section 3 are $Q$-regular.

### 3. Application to self-conformal spaces

Let $M$ be a $d$-dimensional Riemann manifold and $G = \{ g_i \}_{i=1}^\ell$ a conformal iterated function system (IFS) of class $C^{1+\varepsilon}$ on $M$, i.e., $g_i$ are conformal contractions with tangent maps satisfying a Hölder condition of exponent $\varepsilon$. Let $X \subset M$ be the self-conformal set corresponding to $G$, that is, $X$ is the unique compact set satisfying $X = \bigcup_{i=1}^\ell g_i(X)$. We suppose that the IFS $G$ satisfies the strong separation condition, i.e., $g_i(X) \cap g_j(X) = \emptyset$ for $i \neq j$. Let $S : X \to X$ be the inverse map of $G$ on $X$, that is, the restriction of $S$ on $g_i(X)$ is $g_i^{-1}$. Then $(X, S)$ becomes a dynamical system. It is well known that (see e.g. [7, Chapter 5]) there exists a unique probability measure $H$ on $X$, called the natural measure, which is $S$-invariant, ergodic and $Q$-regular, $Q$ being the dimension of $X$. 
We will apply the auxiliary results from the previous section to determine the essential dimension of $E$.

Instead of considering the continuous sequence $\{A(H, x, r), r > 0\}$, we will use the discrete one $\{A(H, x, |DS^n(x)|^{-1}), n \in \mathbb{N}\}$, where $DS^n$ is the tangent map of $S^n$. Since $|DS^{n+1}(x)|/|DS^n(x)| = |DS(S^n(x))| \in (1, \max_x |DS(x)|)$ for all $n \geq 1$, the limit behavior of $A(H, x, r)$ when $r \to 0$ is the same as that of $A(H, x, |DS^n(x)|^{-1})$ when $n \to \infty$.

We write

$$A(H, x, |DS^n(x)|^{-1}) = \frac{1}{\log |DS^n(x)|} \sum_{k=0}^{n-1} f_k(x),$$

where

$$f_k(x) = \int_{|DS^{k+1}(x)|}^{|DS^k(x)|} \mathcal{H}(B(x, t)) t^{-Q-1} dt.$$  

In our context, it is known that (see e.g. [6, Proposition 4.1], [7, Chapter 6.2]) the functions $\{f_k\}_k$ satisfy for all $k \geq 0$ and all $x \in X$

$$|f_n(S^k x) - f_{n+k}(x)| < \varepsilon_n$$  \hspace{1cm} (3.1)

where $\varepsilon_n \to 0$.

Recall that $X(\alpha) = \{x \in X : A(H, x) = \alpha\}$ and $f(\alpha) = \dim_H(\alpha)$. We will make use of the multifractal properties of $X(\alpha)$ that we present now. First, we introduce some notions and results. For simplicity of presentation, we express these results in the context of self-conformal sets/measures, although they are valid in a much more general setting.

**Notations.** Let $\Lambda = \{1, \cdots, \ell\}$. Recall that $g_i$, for $i \in \Lambda$, are conformal contractions. For $u = u_1 \cdots u_k \in \Lambda^k$ we write $g_u = g_{u_1} \circ \cdots \circ g_{u_k}$. Let $X_u = g_u(X)$. Denote $\Lambda^* = \bigcup_{n \geq 1} \Lambda^n$ and for $u \in \Lambda^*$, let $[u] = \{(v_n)_{n \geq 1} \in \Lambda^\infty : v_1 = u_1, \ldots, v_n = u_n\}$. For any $x \in X$, there exists $(u_n)_{n \geq 1} \in \Lambda^\infty$ such that $\{x\} = \lim_n g_{u_n^r}(X) =: g_{u_n^r}(X)$ where we write $u_1^n = u_1 \cdots u_n$. The transformation $S$ can be defined as $\{S^n(x)\} = g_{u_n^r}(X)$.

A sequence $\Phi = \{\varphi_n\}$ of functions $\varphi_n : X \to \mathbb{R}$ is called *asymptotically additive* if for each $\varepsilon > 0$ there exists a continuous function $\varphi : X \to \mathbb{R}$ such that

$$\limsup_{n \to \infty} \frac{1}{n} \sup_{x \in X} |\varphi_n(x) - A_n \varphi(x)| < \varepsilon$$  \hspace{1cm} (3.2)

where $A_n \varphi = \sum_{k=0}^{n-1} \varphi \circ S^k$. If $\varphi_n = A_n \varphi$ for all $n$, then $\Phi$ is called *additive*. 
As a consequence of (3.1), the sequence \( \{ \sum_{k=0}^{n-1} f_k \}_n \) is asymptotically additive. Indeed, for any \( \varepsilon > 0 \), there exists \( N \geq 1 \) such that \( \varepsilon_N < \varepsilon \), then by (3.1) we have

\[
\limsup_{n \to \infty} \frac{1}{n} \sup_{x \in X} \left| \sum_{k=0}^{n-1} f_k(x) - A_n f_N(x) \right| < \varepsilon_N.
\]

Now, we introduce the notion of pressure function. Let \( \Phi = \{ \varphi_n \}_n \) be a sequence of continuous function \( \varphi_n : X \to \mathbb{R} \). The pressure function associated to \( \Phi \) is defined by

\[
P(\Phi) = \limsup_{n \to \infty} \frac{1}{n} \log \sum_{u \in \Lambda^n} \sup_{x \in X_u} \exp(\varphi_n(x)).
\]

(3.3)

Actually, when \( \Phi \) is asymptotically additive, we can replace \( \limsup \) by \( \lim \) in the definition of \( P(\Phi) \). Indeed, from the asymptotically additivity of \( \varphi_n \), we deduce that for any \( \varepsilon > 0 \) there exists \( \varphi : X \to \mathbb{R} \) such that

\[
\sup_{x \in X} |\varphi_n(x) - A_n \varphi(x)| \leq n\varepsilon, \quad \text{for } n \gg 1.
\]

(3.4)

So, \( B_n := \sum_{u \in \Lambda^n} \sup_{x \in X_u} \exp(\varphi_n(x)) = (Ce^n)^\pm \sum_{u \in \Lambda^n} \sup_{x \in X_u} \exp(A_n \varphi(x)) \) for some constant \( C > 0 \), where the notation \( A = C \pm B \) means that \( C^{-1}B \leq A \leq CB \). Since the sequence \( \tilde{B}_n := \sum_{u \in \Lambda^n} \sup_{x \in X_u} \exp(A_n \varphi(x)) \) is sub-additive, the limit \( \lim \frac{1}{n} \log \tilde{B}_n \) exists. So we have

\[
|\liminf_{n} \frac{1}{n} \log B_n - \limsup_{n} \frac{1}{n} \log B_n| \leq \varepsilon.
\]

Letting \( \varepsilon \to 0 \) shows that the limit \( \lim \frac{1}{n} \log B_n \) exists.

Let \( \mathcal{M}(X, S) \) be the set of all \( S \)-invariant probability measures on \( X \). For \( \mu \in \mathcal{M}(X, S) \) and an asymptotically additive sequence \( \Phi = \{ \varphi_n \} \), define

\[
\Phi_*(\mu) := \lim_{n \to \infty} \int_X \frac{\varphi_n(x)}{n} d\mu(x).
\]

By (3.2), the limit in the above definition exists. Note that since \( \mu \) is \( S \)-invariant, we have \( \int_X \frac{A_n \varphi(x)}{n} d\mu(x) = \int_X \varphi \, d\mu \) for all \( n \). (If \( \mu \) is ergodic, then by Birkhoff’s ergodic theorem we deduce that \( \Phi_*(\mu) \) is the \( \mu \)-almost sure limit of \( \frac{\varphi_n(x)}{n} \) as \( n \to \infty \)). Further, it is known (see [10, Lemma A.4], [2, Proposition 4]) that the map \( \mu \mapsto \Phi_*(\mu) \) is continuous in the weak-star topology.

Let us return to the set \( X(\alpha) \). Denote \( F = \{ \sum_{k=0}^{n-1} f_k \}_n \) and \( \log DS = \{ \log |DS^n| \}_n \). Then \( F \) is asymptotically additive and \( DS \) is additive. Let

\[
\Omega = \left\{ \frac{F_*(\mu)}{\log DS_*(\mu)} : \mu \in \mathcal{M}(X, T) \right\}.
\]
We will use the following multifractal properties (Proposition 3.1) of $X(\alpha)$, most of them are from [2, Theorem 1] (see also [10]). Before presenting those properties, we need to introduce the notion of $u$-dimension. We will present this notion in our setting of self-conformal sets/measures.

Let $u : X \to \mathbb{R}^+$ be a continuous function. For each word $v \in \Lambda^n$, we write $u(v) = \sup \left\{ \sum_{k=0}^{n-1} u(S^k x) : x \in X_v \right\}$.

Given a set $F \subset X$ and $\alpha \in \mathbb{R}$, we define

$$N(F, \alpha, u) = \lim_{n \to \infty} \inf \sum_{v \in \Gamma} \exp(-\alpha u(v))$$

where the infimum is taken over all countable collections $\Gamma \in \bigcup_{k \geq n} \Lambda^k$ such that $F \in \bigcup_{v \in \Gamma} X_v$. The $u$-dimension of $F$ with respect to $S$ is defined by

$$\dim_u(F) = \inf \{ \alpha \in \mathbb{R} : N(F, \alpha, u) = 0 \}.$$ 

Note that if $u = \log |DS|$, then the $u$-dimension $\dim_u(F)$ coincides with the Hausdorff dimension $\dim_H(F)$. This follows immediately from the existence of constants $c_1, c_2 > 0$ such that $c_1 \text{diam} X_v^\alpha \leq \exp(-\alpha u(v)) \leq c_2 \text{diam} X_v^\alpha$.

**Proposition 3.1.** The following statements hold:

1. The set $\Omega$ is a closed interval.
2. We have $X(\alpha) \neq \emptyset$ if and only if $\alpha \in \Omega$ and if $\alpha \in \Omega$, then

$$\dim_u(X(\alpha)) = \max \left\{ \frac{h_\mu(S)}{\int_X u \, d\mu} : \mu \in \mathcal{M}(X,T) \text{ and } \frac{F_\ast(\mu)}{\log |DS|_\ast(\mu)} = \alpha \right\}.$$

In particular,

$$f(\alpha) = \max \left\{ \frac{h_\mu(S)}{\int_X \log |DS| \, d\mu} : \mu \in \mathcal{M}(X,T) \text{ and } \frac{F_\ast(\mu)}{\log |DS|_\ast(\mu)} = \alpha \right\}.$$

Here, $h_\mu(S)$ denotes the measure-theoretic entropy of $\mu$ with respect to $S$.

3. The function $f$ obtains its maximum at some $\alpha_{\min} < \alpha_0 < \alpha_{\max}$ and $f(\alpha_0) = Q$.
4. $A(\mathcal{H}, x) = \alpha_0$ for $\mathcal{H}$-almost all $x \in X$.
5. The function $f : \text{int}(\Omega) \to \mathbb{R}$ is continuous.
6. If $\alpha \in \Omega$, then

$$\inf_{q \in \mathbb{R}} P(q(F - \alpha \log DS) - f(\alpha) \log DS) = 0.$$ 

7. $\mathcal{H}(X(0, \beta, r)) = O(r^{Q - f(\beta) - \varepsilon})$ for all $0 < \beta \leq \alpha_0$ and all $\varepsilon > 0$. 

Proof. The statements (2), (5) and (6) can be found in [2, Theorem 1]. Note that the definition of pressure function given in [2] is different from ours, but these two definitions actually give the same pressure function (see [1, Sections 2.2 and 4.2.2], [22, Proposition 3]).

The statements (3) and (4) can be deduced from [6]: in Proposition 4.1 of [6] it is proved that there exists a constant $\alpha_0 > 0$ such that $D(H, x) = \alpha_0$ for $H$-a.e. $x$, so $f(\alpha_0) = \dim(H) = \dim_H(X) = Q$ which is the maximum of $f$.

For the statement (1), since the map $\mu \mapsto F^\ast(\mu) \log DS^\ast(\mu)$ is continuous and $M(X, T)$ is a compact and convex set, we only need to notice that a subset of $\mathbb{R}$, which is the image of a compact convex set under a continuous map, must be a closed interval.

We give a proof for (7) in Appendix A, see Lemma A.1. □

As a consequence of (5), (7) and Proposition 2.6, we have:

**Theorem 3.2.** If $m = \max_{\alpha \in \Omega} f(\alpha) - \gamma \alpha \geq 0$, then almost surely $\dim_H(E) \leq m$ and $\dim_H(E) \geq m$ with positive probability. If $m < 0$, then $E = \emptyset$ almost surely.

**Example 3.3.** Suppose that $X$ is a self-similar set with equal contraction ratios (e.g. the classical ternary Cantor set), that is, there is constant $0 < a < 1$ such that $|g_i| = a$ for all $i, j \in \Lambda$. Then, in this case, $DS$ is constant on $X$ and $F$ is an additive sequence (see [7, Chapter 6.2]). Moreover $F$ is Hölder continuous. It is well known that (see e.g. [8, 25, 23]) the multifractal spectrum $f(\alpha)$ is analytical, strictly convex on $\Omega$ and for any $\alpha \in \Omega$ we have

$$f(\alpha) = \inf_{q \in \mathbb{R}} \left( \tilde{P}(q) - \alpha q \right)$$

where $\tilde{P}(q) = \frac{P(qF)}{-\log a}$. We make two remarks:

1. Observe that since $f'(\alpha_0) = 0$, we have $m > Q - \gamma \alpha_0$. Thus, the almost sure dimension of $E$ is not due to the $\mathcal{H}$-almost sure value of $A(H, x)$ but is affected by the multifractal behaviour of the average densities.

2. From (3.5), one can show that $m(\gamma) = \tilde{P}(-\gamma) = \frac{P(-\gamma F)}{-\log a}$. This means that the critical value (about the parameter $\gamma$) for the emptiness (or for the positivity of the Hausdorff dimension) of $E$ is the unique zero of the pressure function (the pressure function in our case is strictly monotone).

**Remark 3.4.** (ii) It seems plausible that in Theorem 3.2, $\dim_H(E)$ is equal to the essential dimension a.s. conditioned on $E \neq \emptyset$. In other words, $\mathbb{P}(E \neq \emptyset$ and $\dim_H(E) < m) = 0$. However, the proof only implies $\dim_H(E) = m$ a.s. on $\nu(X) > 0$, where $\nu$ is the random measure as in Lemma 2.4 corresponding to the value of $\alpha$ so that $m = f(\alpha) - \gamma \alpha$. We expect that $\mathbb{P}(\nu(X) = 0$ and $E \neq \emptyset)$, but haven’t been able to prove this. As pointed out in [26], this problem is open also in the case of $X = [0, 1]$, $\mathcal{H} = \mathcal{L}.$
Appendix A.

In this Appendix, we give the proof of the following lemma which is the statement (7) of Proposition 3.1.

Lemma A.1. Under the setting of Proposition 3.1, we have
\[ \mathcal{H}(X(0, \beta, r)) = O(r^{Q-f(\beta)-\varepsilon}) \]
for all \( 0 < \beta \leq \alpha_0 \) and all \( \varepsilon > 0 \).

Notations and classical estimates. For \( u \in \Lambda^* \), let \( \tilde{u} \) be the word obtained by erasing the last letter. For \( 0 < \tau < 1 \), consider the “cut-set”
\[ W_\tau = \{ u \in \Lambda^* : \text{diam}(g_u(X)) \leq \tau \text{ and diam}(g_{\tilde{u}}(X)) > \tau \}. \]

It is clear that for any \( 0 < \tau < 1 \), \( \Lambda^\infty = \bigsqcup_{u \in W_\tau} [u] \) and the IFS \( \{ g_u \}_{u \in W_\tau} \) generates the same attractor \( X \), moreover \( \mathcal{H} \) is the natural measure associated to \( \{ g_u \}_{u \in W_\tau} \). For any \( x \in X \), there exists \( (v_n)_{n \geq 1} \in W_\tau^\infty \) such that \( \{ x \} = \lim_n g_{v_n}(X) =: g_{v_\infty}(X) \). We denote the inverse map corresponding to the IFS \( \{ g_u \}_{u \in W_\tau} \) by \( S_\tau \), so that we have \( \{ S_\tau^\infty(x) \} = g_{v_\infty}(X) \).

A well known calculation (see e.g. [21]) shows that a \( C^{1+\varepsilon} \) conformal iterated function system satisfies the bounded distortion principle: there exists \( L > 1 \) such that
\[ L^{-1} \leq \frac{\| g_u'(x) \|}{\| g_u'(y) \|} \leq L \text{ for all } u \in \Lambda^*, x, y \in X. \]

Let \( \lambda_0 = \min\{ \| g_i'(x) \| : i \leq \ell, x \in X \} > 0 \). Then for any \( u = u_1 \cdots u_n \in \Lambda^* \) and \( y \in X \),
\[ \| g_u'(y) \| = \| g_u(g_{u_n}(y)) \| \| g_{u_n}'(y) \| \geq L^{-1} \lambda_0 \max_{z \in X} \| g_u'(z) \|. \]

Now let \( u \in W_\tau \). Then
\[ \tau \leq \text{diam}(g_u(X)) \leq \max_{z \in X} \| g_u'(z) \| \text{diam}(X) \leq L \lambda_0^{-1} \text{diam}(X) \min_{z \in X} \| g_u'(z) \|. \]

On the other hand, \( X = g_u^{-1}(g_u(X)) \) so we have
\[ \text{diam}(X) \leq \max_{z \in X} \| (g_u')^{-1}(z) \| \text{diam}(g_u(X)) \leq \max_{z \in X} \| (g_u')^{-1}(z) \| \cdot \tau \]
and
\[ \max_{z \in X} \| g_u'(z) \| = \left( \min_{z \in X} \| (g_u')^{-1}(z) \| \right)^{-1} \leq L \tau \text{diam}(X)^{-1}. \]

So there exists a constant \( C > 1 \) such that for any \( 0 < \tau < 1 \) and any \( u \in W_\tau \), we have
\[ \tau C^{-1} \leq \min_{z \in X} \| g_u'(z) \|, \max_{y \in X} \| g_u'(y) \| \leq \tau C. \quad (A.1) \]
From (A.1), we deduce that
\[
\tau^{-n}C^{-n} \leq \min_{z \in X} \|DS^n_\tau(z)\|, \max_{y \in X} \|DS^n_\tau(y)\| \leq \tau^{-n}C^n. \tag{A.2}
\]

Now we can give the proof of Lemma A.1.

**Proof of Lemma A.1.** Fix \(x \in X\) and a small \(0 < r < 1\). Let \(n = n(x, r) \in \mathbb{N}\) be such that
\[
|DS^{n+1}_\tau(x)|^{-1} \leq r \leq |DS^n_\tau(x)|^{-1}.
\]
From (A.2), we know that
\[
\log \frac{r}{\log \tau - \log C} \leq n \leq \log \frac{r}{\log \tau + \log C}.
\]
Here and in the rest of the proof, we always take a \(\tau < C^{-1}\) so that \(\log \tau + \log C < 0\). Then we have
\[
\int_1^r \mathcal{H}(B(x, t))t^{-Q-1}dt \geq \int_{DS^n_\tau(x)}^1 \mathcal{H}(B(x, t))t^{-Q-1}dr \geq \log |DS^{n+1}_\tau(x)|.
\]
So we get
\[
\{x \in X : A(\mathcal{H}, x, r) \leq \beta\} \subset \left\{x \in X : \int_{DS^n_\tau(x)}^1 \mathcal{H}(B(x, t))t^{-Q-1}dr \leq \beta \right\} =: A_{\tau,n}.
\]
Thus we have
\[
\frac{\log \mathcal{H}(X(0, \beta, r))}{-\log r} \leq \frac{\log \mathcal{H}(A_{\tau,n})}{-\log r} \leq \frac{\log \mathcal{H}(A_{\tau,n})}{\log |DS^{n+1}_\tau(x)|} \leq \frac{\log \mathcal{H}(A_{\tau,n})}{(n + 1)(-\log \tau + \log C)}.
\]
For proving the claim of the lemma we only need to show that
\[
\limsup_{\tau \to 0^+} \limsup_{n \to \infty} \frac{\log \mathcal{H}(A_{\tau,n})}{-n \log \tau} \leq Q - f(\beta).
\]
Recall that we can rewrite \(A_{\tau,n}\) as
\[
A_{\tau,n} = \left\{x \in X : \frac{\sum_{k=0}^{n-1} f_k(x)}{\log |DS^{n+1}_\tau(x)|} \leq \beta \right\}
\]
where \(f_k(x) = \int_{DS^n_\tau(x)}^1 \mathcal{H}(B(x, t))t^{-Q-1}dr\) is asymptotically additive for the system \((X, S_\tau)\). By Chebyshev’s inequality, for any \(\lambda \geq 0\)
\[
\mathcal{H}(A_{\tau,n}) \leq \int_X \exp \left(\lambda \left(\beta \log |DS^{n+1}_\tau(x)| - \sum_{k=0}^{n-1} f_k(x)\right)\right) d\mathcal{H}(x)
\]
\[
\leq \sum_{\nu_1^\pi \in W^\pi} \mathcal{H}(g_{\nu_1^\pi}(X)) \sup_{x \in g_{\nu_1^\pi}(X)} \exp \left(\lambda \left(\beta \log |DS^{n+1}_\tau(x)| - \sum_{k=0}^{n-1} f_k(x)\right)\right).
\]
Since $H$ is the natural measure of the IFS $(g_u)_{u \in W}$, we have that $H(g_{v_n}^\tau(x)) \asymp \exp(-Q \log |DS^n_\tau(x)|)$ for any $x \in g_{v_n}^\tau(X)$. Whence

$$H(A_{\tau,n}) \lesssim \sum_{v_n^\tau \in W^n} \sup_{x \in g_{v_n}^\tau(X)} \exp \left( \lambda \left( \beta \log |DS^{n+1}_\tau(x)| - \sum_{k=0}^{n-1} f^\tau_k(x) \right) - Q \log |DS^n_\tau(x)| \right), \quad (A.3)$$

whenever $\lambda \geq 0$. Note that $|\log |DS^{n+1}_\tau(x)| - \log |DS^n_\tau(x)|| \leq \max_{x \in X} \log |DS_\tau(x)|$. Taking logarithms and dividing both sides of (A.3) by $n$ and then taking limsup we get

$$\limsup_{n} \frac{\log H(A_{\tau,n})}{n} \leq P_{\tau}(\lambda(\beta \log DS_\tau - F_\tau) - Q \log DS_\tau), \quad \lambda \geq 0,$$

where $P_{\tau}(\lambda(\beta \log DS_\tau - F_\tau) - Q \log DS_\tau)$ is the pressure function (of the system $(X, S_\tau)$) associated to the sequence of functions

$$\left\{ \lambda \left( \beta \log |DS^n_\tau(x)| - \sum_{k=0}^{n-1} f^\tau_k(x) \right) - Q \log |DS^n_\tau(x)| \right\}.$$

We now show that the above inequality holds also when $\lambda < 0$. For this, we only need to show that $P_{\tau}(\lambda(\beta \log DS_\tau - F_\tau) - Q \log DS_\tau) \geq 0$ for $\lambda < 0$. Fix $\lambda < 0$. Denote $B_n = \int_X \exp \left( \lambda \left( \beta \log |DS^n_\tau(x)| - \sum_{k=0}^{n-1} f^\tau_k(x) \right) \right) dH(x)$. We are going to prove that $\limsup_n \frac{\log B_n}{n} \geq 0$, which will imply $P_{\tau}(\lambda(\beta \log DS_\tau - F_\tau) - Q \log DS_\tau) \geq 0$.

By Jensen’s inequality we have

$$B_n \geq \exp \left( \int_X \lambda \left( \beta \log |DS^n_\tau(x)| - \sum_{k=0}^{n-1} f^\tau_k(x) \right) dH(x) \right)$$

So

$$\frac{\log B_n}{n} \geq \int_X \lambda \left( \beta \log |DS^n_\tau(x)| - \frac{1}{n} \sum_{k=0}^{n-1} f^\tau_k(x) \right) dH(x). \quad (A.4)$$

We know that

$$\lim_{n \to \infty} \frac{\sum_{k=0}^{n-1} f^\tau_k(x)}{\log |DS^n_\tau(x)|} = \alpha_0, \quad H\text{-a.e. } x$$

Since $\alpha_0 \geq \beta$ and $\lambda < 0$, in view of (A.4), we get

$$\limsup_n \frac{\log B_n}{n} \geq 0.$$
So we have proved that
\[
\limsup_{n} \frac{\log \mathcal{H}(A_{\tau,n})}{n} \leq \inf_{\lambda \in \mathbb{R}} P_{\tau}(\lambda(\beta \log DS_{\tau} - F_{\tau}) - Q \log DS_{\tau}).
\]

For completing the proof, we only need to show that
\[
\limsup_{\tau \to 0^+} \inf_{\lambda \in \mathbb{R}} \frac{P_{\tau}(\lambda(\beta \log DS_{\tau} - F_{\tau}) - Q \log DS_{\tau})}{- \log \tau} \leq Q - f(\beta). \quad (A.5)
\]

From the definition of the pressure function $P_{\tau}$ and the fact $n(- \log \tau - \log C) \leq \log |DS_{\tau}^{r}(x)| \leq n(- \log \tau + \log C)$, we deduce that
\[
|P_{\tau}(\lambda(\beta \log DS_{\tau} - F_{\tau}) - Q \log DS_{\tau}) - P_{\tau}(\lambda(\beta \log DS_{\tau} - F_{\tau}) - f(\beta) \log DS_{\tau}) - (Q - f(\beta)) \log \tau| \leq 2 \log C.
\]

So for proving (A.5), it is sufficient to show that
\[
\inf_{\lambda \in \mathbb{R}} P_{\tau}(\lambda(\beta \log DS_{\tau} - F_{\tau}) - f(\beta) \log DS_{\tau}) = 0,
\]
but this is exactly the statement [6] of Proposition 3.1 for the system $(X, S_{\tau})$. This ends the proof of the lemma. \qed
