Prevalence of Gynecological Disorders of Goat and Pattern of Drug used at Chuadanga, Bangladesh

Md. Abu Sayeed, Mst. Sawda Khatun, Md. Saiful Bari¹, Amith Kumar Dash², Prodip Kumar Haldar, Biplob Kumar Sarker³

ABSTRACT

Background: Gynecological disorders are the major challenge for Goat production profitability in Chuadanga, a goat dominating district of Bangladesh. To control the gynecological cases of goats in Chuadanga district, it is of utmost importance to estimate the prevalence of them along with their current therapeutic management.

Methods: A cross sectional study was conducted from May, 2018 to April, 2019 on a total of 89 gynecological cases of goat to estimate the prevalence of different gynecological disorders along with drug prescribing patterns at Chuadanga Sadar Upazilla, Chuadanga, Bangladesh. Relevant data on different gynecological cases of goat were collected from the registered sheets of Upazilla Veterinary Hospital (UVH) and used for this study.

Result: The highest prevalence of gynecological case was of anoestrous (20.2%) followed by abortion (18.0%), retained placenta (16.9%), pyometra (10.1%), dystocia (9.0%), repeat breeding (6.7%) and prolapse of the vagina (5.6%). The prevalence of metritis was 4.5% followed by milk fever (4.5%), prolapse of the rectum (3.4%) and postpartum bleeding (1.1%). Prostaglandin (25.0%) followed by a combination of oxytocin and calcium (18.8%) and combination of oxytetracycline and metronidazole (18.8%) were commonly prescribed drugs for treating abortion cases. Vitamin AD₃ε (33.3%) was prescribed the highest for treating anoestrous. A combination of oxytocin and oxytetracycline (33.3%), followed by oxytocin (26.6%) were predominantly prescribed for treating retained placenta. This study reveals the overall burden of reproductive disorders of goat along with drug prescribing patterns at the Chuadanga, Bangladesh. This outcome will be supportive to know the better treatment strategy against reproductive disorders in goat.

Key words: Goat, Prevalence, Reproductive disorders, Treatment.

INTRODUCTION

The goat is called the “Poor man’s cow”, the second important livestock species in Bangladesh, which have a significant contribution in the pastoral economy and earns a substantial amount of foreign currency by exporting skin and other by-products (Ali et al., 2013; Ahmed et al., 2019). About 25.7 million goat heads are distributed in Bangladesh (Kumar et al., 2018). However, reproductive disorders affect goat production profitability by decreasing milk yield and increasing the culling rate (Talukder et al., 2005). Besides, infertility is a particular problem in goat rearing because of requiring more services per conception and higher incidence of gynecological problems (Purohit, 2006). Overall, 10-30% cases, the lactation is affected by infertility and other reproductive disorders and annually a range of 3-6% herds are discarded in developed countries for gynecological reasons (Humblot, 2001). Gynecological disorders are responsible to slow down the uterine involution and reduction of conception rate which ultimately increases the medication cost and drop off the overall milk production resulting a considerable economic loss of the farmers (Khair et al., 2014). Chuadanga, a district city of Bangladesh, where goat is the common livestock but there is a lack of constructive study on reproductive disease status of goats at this area (Talukder et al., 2005; Parvez et al., 2014). Hence, this area has been selected for the study.

Therapeutic management is the most commonly practiced way to deal with the gynecological cases in goats. Bangladesh. This outcome will be supportive to know the better treatment strategy against reproductive disorders in goat.
disorders in goats and to describe the patterns of drugs prescribed against them at the Upazilla Veterinary Hospital (UVH) of Chuadanga Upazilla, a south-western district of Bangladesh.

**MATERIALS AND METHODS**

**Study site and veterinary service**

Chuadanga district of Bangladesh having a 289.59 square km of plain land area is located in between 23°29’ to 23°42’ N and 88°47’ to 89°00’E (Anonymous, 2010). The government of Bangladesh has established a Veterinary hospital at almost every Upazilla (sub-district) to provide animal healthcare facility which is operated by Upazilla Livestock Officer (ULO), Veterinary Surgeon (VS) and para-vets as supporting staffs (Samad et al., 2020).

A cross-sectional study was undertaken on different gynecological cases of goat recorded at UVH of Chuadanga Sadar during May, 2018 to April, 2019. Data on different gynecological cases of goat were separated from the stock of manually recorded registered sheets of UVH and used for this study.

**Data organization**

Relevant information from the data sheet was collected and collated in Microsoft Excel spreadsheet-2007 on the headings of - case registration number, date, owner’s name and address, owners complain, animal’s age, breed, rearing system, types of gynecological cases and drugs that were prescribed.

The data were sorted, cleaned and coded as necessary before transferring to STATA IC-13 (Stata Corp, 4905, Lakeway Drive, College Station, Texas 77845, USA) for statistical analysis.

Goats were divided into four categories according to weight and age separately, based on percentile. Body condition score was defined according to the criteria set by Villaquiran *et al.* (2004) for goat, where BCS-1, 2, 3, 4 and 5 were expressed as Cachectic, Poor, Fair, Good and Excellent category, respectively. Season was defined as summer (March-June), rainy (July-October) and winter (November-February) as described by Sayeed *et al.* (2020).

**Statistical analysis**

Descriptive analysis was performed on different gynecological disorders along with different factors and drugs prescribed pattern. The estimated output has been expressed as frequency number and percentage.

**RESULTS AND DISCUSSION**

Prevalence of different gynecological disorders of goats: Eighty-nine gynecological cases were recorded during the study and the prevalence of different gynecological disorders has been presented in Table 1. The calculated prevalence of anoestrus (20.2%) was lower than the reported prevalence of 31.25% by Lucky *et al.* (2016) in Bangladesh. This disagreement might be due to the differences in study area.

The estimated prevalence of abortion was 18.0% in this study which was higher than 12.5%, revealed in goat population by Lucky *et al.* (2016) in Bangladesh. Besides, the prevalence of retained placenta was 16.9% which is much higher than that of 1.02% and 6.25% prevalence observed by Alam *et al.* (2015) and Lucky *et al.* (2016) respectively, in different districts of Bangladesh. Again, the prevalence of pyometra was 9.0% which is in line with the previously estimated prevalence (9.37%) in goats by Lucky *et al.* (2016). The discrepancies between the study findings and previously estimated prevalence is due to difference in breed in different study area (Alam *et al.*, 2015).

**Table 1**: Frequency distribution of different gynecological disorders in goats recorded at the UVH.

| Name of Cases               | n   | %    |
|----------------------------|-----|------|
| Anoestrous                 | 18  | 20.2 |
| Abortion                   | 16  | 18.0 |
| Retained placenta          | 15  | 16.9 |
| Pyometra                   | 9   | 10.1 |
| Dystocia                   | 8   | 9.0  |
| Repeat breeding            | 6   | 6.7  |
| Prolapse of the vagina     | 5   | 5.6  |
| Metritis                   | 4   | 4.5  |
| Milk fever                 | 4   | 4.5  |
| Prolapse of the rectum     | 3   | 3.4  |
| Postpartum bleeding        | 1   | 1.1  |

The prevalence of retention placenta was also higher in the semi-intensive system than tethering system which is in accordance with Islam *et al.* (2015). Retained placenta cases were higher during summer in correspond to other season which is in line with previous studies (Faruque *et al.*, 2010). However, this finding is differed with Islam *et al.* (2015) who reported higher prevalence of retained placenta during rainy season. Again, the prevalence of anoestrus was higher during winter followed by summer and rainy season supported by Islam *et al.* (2015). In Bangladesh goat feeding is largely affected by grazing. Winter season affects pasture grazing, produce nutritional inadequacy that might be contributed to development of anoestrous (Dutt *et al.*, 2011).

A higher prevalence of abortion was calculated in semi-intensive than tethering system which is in accordance with (Engeland *et al.*, 1998). Again, anoestrus and retained placenta was also higher in the semi-intensive system than tethering which may be due to the difficulties to maintain a good health status and prevention of unusual mating in semi-intensive system.

The crossbred goat was more likely to abort than others,
which differed with Unanian and Silva (1989) who reported higher abortion rates in exotic breeds than in native breeds. Again, anoestrous was higher in crossbreds, which may be due to poor breeding management at the farm level of Bangladesh agreed with Alejandrino et al. (1999). However, higher prevalence of retain placenta estimated at Black Bengal goat might be due to increased litter size (Hassan et al., 2007).

For age category, retained placenta and abortion cases were proportionately higher among young (16-18 months old) does than older ones which is supported by Mellado et al. (2004) and Ali et al. (2013). However, anoestrous was higher in 9-15 months of aged does which is agreed with Islam et al. (2015).

Among BCS category, the animals with a fair BCS were more prone to gynecological disorders including abortion, retained placenta and anoestrous which can be metaphorized with the findings of Mellado et al. (2004) who reported the change of abortion rate with the change of one unit of BCS. Moreover, the abortion and retained placenta was higher among the goat with lower body weight which might be due to poor feeding and nutrition of the animals supported by Lucky et al. (2016).

### Table 2 Frequency distribution of major gynecological disorders in goats according to different variables at the UVH.

| Variable               | Class          | Abortion, n (%) | Anoestrous, n (%) | Retained placenta, n (%) | p-value |
|------------------------|----------------|-----------------|-------------------|--------------------------|---------|
| **Season**             |                |                 |                   |                          |         |
| Summer                 | 6 (37.4)       | 6 (33.3)        | 8 (53.3)          |                          | 0.8     |
| Rainy                  | 3 (18.8)       | 5 (27.8)        | 3 (20)            |                          |         |
| Winter                 | 7 (43.8)       | 7 (38.9)        | 4 (26.7)          |                          |         |
| **Rearing system**     |                |                 |                   |                          |         |
| Semi-Intensive         | 12 (75.0)      | 14 (77.8)       | 10 (66.7)         |                          | 0.6     |
| Tethering              | 4 (25.0)       | 4 (22.2)        | 5 (33.3)          |                          |         |
| **Breed**              |                |                 |                   |                          |         |
| Non-descriptive        | 10 (62.5)      | 7 (38.9)        | 4 (26.7)          |                          | 0.3     |
| Black Bengal           | 5 (31.3)       | 6 (33.3)        | 7 (46.7)          |                          |         |
| Jamnnapari             | 1 (6.2)        | 5 (27.8)        | 4 (26.6)          |                          |         |
| **Age (mo)**           |                |                 |                   |                          |         |
| 9-15                   | 3 (18.8)       | 6 (33.3)        | 4 (26.7)          |                          | 0.6     |
| 16-18                  | 6 (37.5)       | 2 (11.1)        | 6 (40.0)          |                          |         |
| 19-24                  | 4 (25.0)       | 6 (33.3)        | 3 (20.0)          |                          |         |
| 25-27                  | 3 (18.7)       | 4 (22.3)        | 2 (13.3)          |                          |         |
| **Body condition score** |             |                 |                   |                          |         |
| Cachectic              | 1 (6.3)        | 1 (5.6)         | 1 (6.7)           |                          | 0.9     |
| Poor                   | 5 (31.3)       | 4 (22.2)        | 2 (13.3)          |                          |         |
| Fair                   | 6 (37.4)       | 7 (38.9)        | 8 (53.3)          |                          |         |
| Good                   | 4 (25.0)       | 6 (33.3)        | 4 (26.7)          |                          |         |
| **Body weight (kg)**   |                |                 |                   |                          |         |
| 15-20                  | 6 (37.4)       | 4 (22.2)        | 9 (60)            |                          | 0.3     |
| 21-24                  | 3 (18.7)       | 2 (11.1)        | 2 (13.3)          |                          |         |
| 25-27                  | 3 (18.7)       | 6 (33.3)        | 1 (6.7)           |                          |         |
| 28-35                  | 4 (25.0)       | 6 (33.3)        | 3 (20.0)          |                          |         |

In abortion cases, prostaglandin, a combination of oxytocin and oxytetracycline, and oxytocin with metronidazole were commonly prescribed. To remove the fetal membrane with other contents, oxytocin has been suggested to administer, whereas calcium was suggested to increase the tonicity of the smooth muscle of the uterus (Hammond, 2009). Oxytocin with antibiotic was commonly used in the treatment of retained placenta (Cohen et al., 1995).

Vitamin AD₃E, combined GnRH with Vitamin AD₃E, amino acid, selenium and vitamin E were more frequently prescribed for managing anoestrous because selenium, zinc, vitamin A and E are essential sources for health and reproductive performance of small ruminants (Blache et al., 2008).

Among other reproductive disorders of goats, vaginal prolapse was treated with intravenous and oral administration of calcium. The administration of oxytocin along with calcium solution was practiced for management of dystocia which is in line with the earlier study conducted by Broutis et al. (2004). In milk fever, the amino acid was prescribed along with calcium which is supported by Oetzel and Goff (1998).

Metronidazole was used in pyometra to treat protozoal...
### Table 3: Frequency distribution of drugs prescribed for gynecological disorders of goats at the UVH.

| Drug                        | Abortion n (%) | Anoestrous n (%) | Retained placenta n (%) | Postpartum bleeding n (%) | Rectal prolapse n (%) | Metritis n (%) | Milk fever n (%) | Vaginal prolapse n (%) | Repeat breeding n (%) | Dystocia n (%) | Pyometra n (%) |
|-----------------------------|----------------|------------------|--------------------------|----------------------------|-----------------------|---------------|------------------|------------------------|------------------------|----------------|-----------------|
| GnRH                        | -              | 4 (22.2)         |                          |                            |                       |               |                  |                        |                        |                |                 |

infection and oxytocin was also used to remove the pus contents from the uterus which is different than the treatment option reported by El-Tahawy and Fahmy (2011), where PGF$_2$α and oxytetracycline was used to treat pyometra, this difference is due to species variation in the study. Again, a combination of penicillin and streptomycin or oxytetracycline and metronidazole were also used in metritis of goats where long acting oxytetracycline has been suggested by (Majed, 1994).

CONCLUSION
The study estimated the prevalence of major gynecological disorders including anestrous, abortion, retained placenta, pyometra and dystocia along with most commonly prescribed drugs against different gynecological disorders used in goats of Chuadanga district of Bangladesh. The knowledge derived from this study can be used in educational and research purposes, finding the future research area and developing treatment protocols for gynecological disorders in goats. The authors suggest to conduct further study for the identification and characterization of etiological factors of various gynecological disorders in goats.

ACKNOWLEDGEMENT
The authors would like to express gratitude to the Upazilla Livestock Officer and Veterinary Surgeon of Chuadanga Sadar Upazilla, Chuadanga for their kind cooperation during the study period.
