ALMOST SYMMETRIC NUMERICAL SEMIGROUPS WITH GIVEN FROBENIUS NUMBER AND TYPE

M.B. BRANCO, I. OJEDA, AND J.C. ROSALES

Abstract. We give two algorithmic procedures to compute the whole set of almost symmetric numerical semigroups with fixed Frobenius number and type, and the whole set of almost symmetric numerical semigroups with fixed Frobenius number. Our algorithms allow to compute the whole set of almost symmetric numerical semigroups with fixed Frobenius number with similar or even higher efficiency that the known ones. They have been implemented in the GAP ([7]) package NumericalSgps ([5]).

1. Introduction

Let \( \mathbb{Z} \) and \( \mathbb{N} \) denote the set of integers and nonnegative integers, respectively. A **numerical semigroup** is a subset \( S \) of \( \mathbb{N} \) that is closed under addition, contains the zero element and has finite complement in \( \mathbb{N} \), that is, \( \mathbb{N} \setminus S \) is a finite set.

Given a nonempty subset \( A \) of \( \mathbb{N} \), we write \( \langle A \rangle \) for the submonoid of \( \mathbb{N} \) generated by \( A \), that is,

\[
\langle A \rangle := \left\{ \sum_{\text{finite}} na \mid n \in \mathbb{N}, a \in A \right\}
\]

It is well known that \( \langle A \rangle \) is a numerical semigroup if and only if \( \gcd(A) = 1 \) (see [14] Lemma 2.1). If \( S \) is a numerical semigroup and \( S = \langle A \rangle \) then we say that \( A \) is a **system of generators** of \( S \). Furthermore if \( S \neq \langle A' \rangle \) for every \( A' \subset A \), then we say that \( A \) is a **minimal system of generators** of \( S \). It is also known that every numerical semigroup admits a unique finite minimal system of generators ([14] Lemma 2.7]). Hence, if \( S \) is a numerical semigroup, we write \( \text{msg}(S) \) for the minimal system of generators of \( S \).

Here and in the following \( S \) will denote a numerical semigroup.

The Frobenius number of $S$ is the largest integer not belonging to $S$ and it is denoted by $F(S)$. A numerical semigroup is irreducible if it cannot be expressed as the intersection of two numerical semigroups properly containing it. A numerical semigroup is said to be symmetric (pseudo-symmetric, resp.) if it is irreducible and its Frobenius number is odd (even, resp).

An integer $x \in \mathbb{Z} \setminus S$ is called a pseudo-Frobenius number if $x + S \setminus \{0\} \subseteq S$ (see [12]). The set of pseudo-Frobenius number of $S$ is denoted by PF(S). The type of the semigroup, denoted by $t(S)$, is the cardinality of PF(S) and it was introduced in [6].

As a consequence of [14, Corollary 4.11 and 4.16], we have the following result.

**Lemma 1.** If $S$ is a numerical semigroup, then:

(a) $S$ is symmetric if and only if $\text{PF}(S) = \{F(S)\}$.

(b) $S$ is pseudo symmetric if only if $\text{PF}(S) = \{F(S), F(S)/2\}$.

Observe that if $S$ is an irreducible numerical semigroups then $t(S) \in \{1, 2\}$ and we have that $t(S) = 1$ if and only if $F(S)$ is odd, equivalently if $S$ is symmetric.

The elements in $\mathbb{N} \setminus S$ are called the gaps of $S$ and the cardinality of the set of gaps of $S$, $g(S)$, is known as the genus of $S$. Following the terminology of [8] (see also [1]) the elements in

$$
N(S) := \{x \in \mathbb{N} \setminus S \mid F(S) - x \in S\}
$$

are called gaps of the first type and the remaining gaps are called gaps of the second type. Set of gaps of the second type is denoted $L(S)$. By [14, Proposition 3.4], one has that if $S$ is symmetric (pseudo-symmetric, resp.) then $L(S) = \emptyset$ (L(S) = \{F(S)/2\}, resp.).

**Definition 2.** A numerical semigroup $S$ is almost symmetric (AS-symmetric, for short) when $L(S) \subseteq \text{PF}(S)$.

Notice that symmetric and pseudo-symmetric semigroups are almost symmetric.

The concept of AS-semigroup was introduced in [1] where the next is proven.

**Proposition 3.** Let $S$ be a numerical semigroup. The following conditions are equivalent:

(a) $S$ is AS-semigroup;

(b) $\text{PF}(S) = L(S) \cup \{F(S)\}$;

(c) $g(S) = \frac{F(S) + t(S)}{2}$.

It is well known (see [10, Proposition 2.2]) that if $S$ is a numerical semigroup then

$$
g(S) \geq \frac{F(S) + t(S)}{2}.
$$
Therefore, we deduce that AS-semigroups are those numerical semigroups with the least possible genus in the set of numerical semigroups with fixed Frobenius number and type (observe that AS-semigroups are maximal in this set).

The main aim of this paper is to give algorithmic methods to compute the whole set of AS-semigroups with fixed Frobenius number and given type. Thus, by Proposition 3 we will solve the optimization problem of the computation of all numerical semigroups with fixed Frobenius number and type, and minimal genus.

An interesting application of our computations is related to the theory of \( S \)–graded minimal free resolutions (see Remark 19).

For our main purpose, we will give two algorithms. The first one will start from the almost symmetric numerical semigroups with Frobenius number \( F \) and smallest possible type (that is, type equals to 1) and the second will start from the almost symmetric numerical semigroup with Frobenius number \( F \) and biggest possible type (that is, type equals to \( F \)). For that reasons, we have called them the ascending and the descending algorithms, respectively.

As an immediate consequence, our algorithms allow to compute set of AS-semigroups with fixed Frobenius number. The ascending algorithm has a running time similar to the algorithm given in [15]. Its main virtue is that it enables to perform the computation with separate processes for each feasible type or even truncate the computation in a range of types. The descending algorithm wins without forgiveness for the previous ones for high Frobenius numbers. A discussion table of timing is included in Section 5.

The referee pointed out an alternative algorithm to compute the set of AS-semigroups with fixed Frobenius number and type that is based in the algorithm to compute the set of numerical semigroups with given pseudo-Frobenius numbers introduced in [3]. We briefly discuss this alternative algorithm in Section 5.

We end this paper with a computational evidence which establishes an apparently relation between the number of AS-semigroups with fixed Frobenius number and given type and the Bras-Amoros’ conjecture on the number of numerical semigroups of a given genus (see Remark 20).

2. Irreducible numerical semigroups and AS-semigroups

Throughout this section, \( F \) and \( t \) are integers and \( S \) denotes a numerical semigroup. Our goal now is to describe the conditions that \( F \) and \( t \) must fulfill for \( S \) to be an AS-semigroup with Frobenius number \( F \) and type \( t \). First we need to recall some useful results.

**Proposition 4.** [15, Theorem 3]. \( S \) is AS-semigroup if and only if there exists an irreducible numerical \( S' \) and \( A \subseteq \text{msg}(S') \) such that
   
   (a) \( S = S' \setminus A \).
   (b) \( F(S')/2 < x < F(S') \), for every \( x \in A \).
   (c) \( x + y - F(S') \notin S \), for every \( x, y \in A \).
In this case, $F(S) = F(S')$ and $t(S) = 2\#A + t(S')$, where $\#$ means cardinality.

Notice that if $A \neq \emptyset$, then $S' \setminus A$ is neither symmetric nor pseudo-symmetric.

Let us denote by $C(F)$ the following numerical semigroup:

- $\{0, \frac{F+1}{2}, \frac{F+1}{2} + 1, \frac{F+1}{2} + 2, \ldots\} \setminus \{F\}$ if $F$ is odd;
- $\{0, \frac{F}{2} + 1, \frac{F}{2} + 2, \ldots\} \setminus \{F\}$ if $F$ is even.

Clearly, $C(F)$ has Frobenius number equal to $F$. Moreover, by Lemma 1, $C(F)$ is irreducible.

**Proposition 5.** [4, Proposition 2.7] The semigroup $C(F)$ is the unique irreducible numerical semigroup with Frobenius number $F$ and such that all its minimal generators are larger than $\frac{F}{2}$.

In the following result we present a necessary and sufficient condition for the existence of an AS-semigroup with given Frobenius number and type.

**Proposition 6.** There exists an almost symmetric semigroup $S$ with $F(S) = F$ and $t(S) = t$ if if and only if $F(S) + t(S)$ is an even number less than or equal to $2F(S)$.

**Proof.** Set $F = F(S)$ and $t = t(S)$. If $S$ is an AS-semigroup, by Proposition 3, $F + t = 2g(S)$ is even. Besides, since $g \leq F$, it follows that $F + t \leq 2F$. Conversely, we distinguish to cases:

- if $F$ is odd, we set $A = \left\{ \frac{F+1}{2}, \frac{F+1}{2} + 1, \ldots, \frac{F+1}{2} + \frac{t-3}{2} \right\}$;
- if $F$ is even, we set $A = \left\{ \frac{F}{2} + 1, \ldots, \frac{F}{2} + \frac{t-2}{2} \right\}$.

Now, if $S' = C(F)$, then, by applying Proposition 4 we conclude that $S' \setminus A$ is an AS-semigroup with $F(S') = F$ and type $t$. \qed

Observe that, if we choose $F$ and $t$ as in Proposition 3 then we can use Proposition 4 to produce an AS-semigroup with Frobenius number $F$ and type $t$, from $C(S)$. Let us see a couple of examples.

**Example 7.** Set $F = 11$ and $t = 5$. By Proposition 6 there exists at least one AS-semigroup with Frobenius 11 and type 5. In this case, the semigroup $C(11)$ is $\{0, 6, 7, 8, 9, 10, 12, 13, \ldots\}$. So, by taking $A = \{6, 7\}$, Proposition 4 ensures that

$$S = C(11) \setminus A = \{0, 8, 9, 10, 12, 13, \ldots\}$$

is an AS-semigroup with $F(S) = 11$ and $t(S) = 5$.

**Example 8.** Set $F = 10$ and $t = 6$. By Proposition 6 there exists at least one AS-semigroup with Frobenius 10 and type 6. In this case, the semigroup $C(10)$ is $\{0, 6, 7, 8, 9, 11, 12, 13, \ldots\}$. So, by taking $A = \{6, 7\}$, Proposition 4 ensures that

$$S = C(10) \setminus A = \{0, 8, 9, 11, 12, 13, \ldots\}$$

is an AS-semigroup with $F(S) = 10$ and $t(S) = 6$. 

\[\text{\footnotesize M. B. Branco and I. Ojeda and J. C. Rosales}\]
3. The ascending algorithm

Let \( F \) and \( t \) be positive integers such that \( F + t \) is an even number lesser than or equal to \( 2F \). The objective in this section is to describe an algorithmic procedure to compute the set

\[
\mathcal{A}(F, t) := \{ S \mid S \text{ is an AS-semigroup with } F(S) = F \text{ and } t(S) = t \}.
\]

In order to reach the almost symmetric numerical semigroups with Frobenius number \( F \) and type \( t \), our algorithm will depart from the almost symmetric numerical semigroups with Frobenius number \( F \) and type 1, that is to say, from the irreducible numerical semigroups with Frobenius number \( F \).

Before presenting the result that supports our algorithm, we need to recall one of the main results in [4] which allows to compute the set \( I(F) \) of all irreducible numerical semigroups with Frobenius number \( F \).

**Proposition 9.** [4, Proposition 2.9] If \( S \in I(F) \), then

\[
(S \setminus \{x\}) \cup \{F - x\} \in I(F),
\]

for every \( x \in \text{msg}(S) \) such that \( \frac{F}{2} < x < F \), \( 2x - F \not\in S \), \( 3x \neq 2F \), \( 4x \neq 3F \) and \( F - x < \min(\text{msg}(S)) \).

Let \( \prec \) be the following binary relation on \( \mathcal{I}(F) \): \( S \prec S' \) if and only if there exists \( S = S_0, S_1, \ldots, S_p = S' \) such that \( S_{i+1} \) is obtained from \( S_i \) by applying Proposition 9. In [4] it is shown that \( \prec \) is an order relation (reflexive, transitive and antisymmetric) on \( \mathcal{I}(F) \) with first element equal to \( C(F) \). In other words, the set \( \mathcal{I}(F) \) forms a rooted tree with root \( C(F) \).

Therefore, one can compute all the irreducible numerical semigroup with Frobenius number \( F \) starting from \( C(F) \).

**Example 10.** Let us compute \( \mathcal{I}(11) \). Using Proposition 9 we compute the elements in \( \mathcal{I}(11) \) that are immediately bigger than

\[
C(11) = \{0, 6, 7, 8, 9, 10, 12, 13 \ldots\} = \langle 6, 7, 8, 9, 10 \rangle,
\]

namely \( \langle 3, 7 \rangle, \langle 4, 6, 9 \rangle \) and \( \langle 5, 7, 8, 9 \rangle \). By repeating the same construction with these three semigroups, we obtain that the first is maximal and the other two produce \( \langle 2, 13 \rangle \) and \( \langle 4, 5 \rangle \), respectively. As these two last are maximal, we are done.

The following figure summarizes the construction flow:
where each edge was marked with the corresponding $x$.

Now, let us write $b(S)$ for the cardinality of the set
\[
\left\{ x \in \text{msg}(S) \mid \frac{F(S)}{2} < x < F(S) \right\}
\]
and define $\mathcal{B}(F, t) := \{ S' \in \mathcal{I}(F) \mid b(S') \geq \lceil \frac{t}{2} \rceil - 1 \}$, being $\lceil \cdot \rceil$ the ceiling operator. Observe that $\mathcal{B}(F, t) \neq \emptyset$, because $C(F) \in \mathcal{B}(F, t)$.

**Theorem 11.** With the notation above, $S$ is an almost symmetric semigroup with Frobenius number $F$ and type $t$ if and only if there exist $S' \in \mathcal{I}(F)$ and a subset $A$ of $\text{msg}(S')$ with cardinality $\lceil \frac{t}{2} \rceil - 1$ such that $S = S' \setminus A$, $F(S')/2 < x < F(S')$ and $x + y - F(S') \notin S' \setminus A$, for every $x, y \in A$.

**Proof.** Let $S$ be an AS-semigroup with Frobenius number $F$ and type $t$. By Proposition 4 there exist $S' \in \mathcal{I}(F)$ and $A \subseteq \text{msg}(S')$ such that $S = S' \setminus A$, $F(S')/2 < x < F(S')$ and $x + y - F(S') \notin S' \setminus A$, for every $x, y \in A$. Moreover, since $t = t(S) = 2\#A + t(S')$, we obtain that $\#A = \frac{t + \delta}{2} - 1$ where $\delta$ is 0 or 1 depending on whether $F$ is even or odd. Now, $F + t$ is an even number, we conclude that $\#A = \lceil \frac{t}{2} \rceil - 1$. The converse follows directly from Proposition 4.

**Algorithm 12.**

**Input:** $F$ and $t$ two positive integers.

**Output:** $\mathcal{A}(F, t)$.

1) Set $\mathcal{A}(F, t) = \emptyset$.

2) If $t > F$ or $F + t$ is odd then return $\mathcal{A}(F, t)$.

3) Compute the set $\mathcal{I}(F)$.

4) Compute the set $\mathcal{B}(F, t) = \{ S' \in \mathcal{I}(F) \mid b(S') \geq \lceil \frac{t}{2} \rceil - 1 \}$.

5) For each $S' \in \mathcal{B}(F, t)$ compute

4.1) $\mathcal{A}(S') = \left\{ A \subseteq \text{msg}(S') \mid \#A = \lceil \frac{t}{2} \rceil - 1, \frac{F(S')}{2} < x < F(S') \text{ and } x + y - F(S') \notin S' \setminus A \right\}$.
4.2) Set \( \mathcal{D}(S') = \{ S' \setminus A \mid A \in \mathcal{A}(S') \} \)

4.3) Append \( \mathcal{D}(S') \) to \( \mathcal{A}(F, t) \).

6) Return \( \mathcal{A}(F, t) \).

The correctness of this algorithm relies on Theorem 11. The algorithm ends because the sets \( \mathcal{B}(F, t) \) and \( \mathcal{A}(S') \), \( S' \in \mathcal{B}(F, t) \), are empty or finite.

**Example 13.** Let us compute the set \( \mathcal{A}(11, 7) \). By Example 10 we have that \( \mathcal{B}(11, 7) = \{ (6, 7, 8, 9, 10), (5, 7, 8, 9) \} \).

- If \( S' = (6, 7, 8, 9, 10) \), then the subsets \( A \) of \( \{ 6, 7, 8, 9, 10 \} \) with cardinality 3 such that \( x + y - 11 \notin S' \setminus A \), for every \( x, y \in A \) are \( \{ 6, 7, 8 \} \) and \( \{ 6, 7, 9 \} \).
- If \( S' = (5, 7, 8, 9) \), then there exists no \( A \) possible.

Hence, by applying Proposition 4

\[
\mathcal{A}(11, 7) = \{ (6, 7, 8, 9, 10) \setminus \{ 6, 7, 8 \}, (6, 7, 8, 9, 10) \setminus \{ 6, 7, 9 \} \\
= \{ (9, 10, 12, 13, 14, 15, 16, 17), (8, 10, 12, 13, 14, 15, 17, 19) \}
\]

We can verify this computation by using the NumericalSgps package (see [5]). It suffices to change the first line in the code provided in [15, Example 5] by

\[ \text{almostnsfromirreducibleAlt} := \text{function}(s,t) \]

and set the variable \( \text{pow} \) as \( \text{Combinations}(\text{msg}, \text{CeilingOfRational}(t/2)-1) \).

The following piece of code will do the rest:

\[
\text{assemigroupswithfrobeniusnumberandtype} := \text{function}(f,t) \\
\text{return Union(Set(} \\
\text{IrreducibleNumericalSemigroupsWithFrobeniusNumber}(f), \\
\text{s->almostnsfromirreduciblealt}(s,t) \\
\text{))};
\]

Indeed, the command \( \text{assemigroupswithfrobeniusnumberandtype}(11, 7) \) will give us all the almost symmetric semigroups of Frobenius number 11 and type 7.

**Remark 14.** Let \( g \) be a positive integer. By Proposition 3 the set of all AS-semigroups with genus \( g \) and type \( t \) and the set of all AS-semigroups with Frobenius number \( F \) and genus \( g \) are \( \mathcal{A}(2g - t, t) \) and \( \mathcal{A}(F, 2g - F) \), respectively. Notice that, by Proposition 6 there exists at least one AS-semigroup with genus \( g \) and type \( t \) for every pair \( (g, t) \) of positive integers such that \( t \leq g \). Analogously, there exists at least one AS-semigroup with Frobenius number \( F \) and genus \( g \) for every pair \( (F, g) \) of positive integers such that \( g \leq F \).

We, finally, observe that since \( t \leq F \) we can compute the set of all AS-semigroup with fixed Frobenius number \( F \), \( \mathcal{A}(F) \), that is nothing but the union of the sets \( \mathcal{A}(F, 2i - F) \) for every \( i = \left\lfloor \frac{F+1}{2} \right\rfloor, \ldots, F \).
assemigroupswithfrobeniusnumber := function(F)

end;

4. THE DESCENDING ALGORITHM

Let $F$ be a positive integer and define $M(F)$ to be the numerical semigroup $\{0, F+1, F+2, \ldots\}$. Clearly, this semigroup has Frobenius number and type equal to $F$. Moreover, since $\mathbb{N} \setminus M(F) = \text{PF}(M(F)) = \{1, \ldots, F\}$, we have that $g = \frac{F+F}{2}$. So, by Proposition 3, $M(F)$ is a almost symmetric.

Lemma 15. The unique numerical semigroup with both Frobenius number and type equal to $F$ is $M(F)$.

Proof. Let $S$ be a numerical semigroup such that $F(S) = t(S) = F$. Since $g(S) \leq F$ and, by (1), $g(S) \geq \frac{F(S)+t(s)}{2} = F$. We conclude that $\mathbb{N} \setminus S = \{1, \ldots, F\}$, that is to say, $S = M(F)$. \hfill \Box

In this section, we will depart from $M(F)$, i.e. the almost symmetric semigroup with Frobenius number and type equal to $F$, in order to “descend” to the set of almost symmetric semigroup with Frobenius number $F$ and type $t \leq F$.

We recall that the least positive integer in a numerical semigroup $S$ is called the \textbf{multiplicity} of $S$ and it is denoted $m(S)$. The following result relates the multiplicity and type of a numerical semigroup.

\textbf{Proposition 16.} [14, Corollary 2.23]. Let $S$ be a numerical semigroup.

Then

\[ m(S) \geq t(S) + 1 \]

\textbf{Theorem 17.} Let $F \geq 5$ and $t \leq F$ be a positive integer greater than 2 such that $F + t$ is even. Then $S$ is an almost symmetric numerical semigroup with Frobenius number $F$ and type $t-2$ if and only if there exist an almost symmetric numerical semigroup $S'$ with Frobenius number $F$ and type $t$, $x \in [t-1, m(S') - 1]$ such that

(a) $S = \{x\} \cup S'$.

(b) $-x + \mathbb{N} \setminus S \subseteq \mathbb{Z} \setminus S$. 

Thus, since $t$ particular, $-F > t - 1$. Let us prove that the type of $S'$ is $t$. By definition, $g(S') = g(S) + 1$. Thus, since

$$F + t(S') \leq g(S') = g(S) + 1 = \frac{F + t}{2} + 1 = \frac{F + t}{2},$$

we obtain that $t(S') \leq t$. Furthermore, $F - x \not\in S'$, otherwise $F = (F - x) + x \in S$, and $x = F - (F - x) \not\in S'$. Thus, $\{x, F - x\} \subseteq PF(S')$. Now, since $y + S' \subseteq S$, for every $y \in PF(S)$, we have that $y + S' \subseteq S$, for every $y \in PF(S)$. If $y + s' = x$, for some $s' \in S' \setminus \{0\}$, then $s' = y = x = m(S) < m(S') \leq s'$, a contradiction. Therefore $PF(S) \subseteq PF(S') \setminus \{x, F - x\}$, in particular, $t - 2 = t(S) \leq t(S') - 2$, that is to say, $t \leq t(S')$. Thus, $t(S') = t$.

From (2) it follows that $g(S') = \frac{F(S) + t(S')}{2}$; so, by Proposition 3, we conclude that $S'$ is almost symmetric.

Conversely, suppose that there exist an almost symmetric numerical semigroup $S'$ with Frobenius number $F$ and type $t$, and $x \in [t - 1, m(S') - 1]$ satisfying (a)-(c). Let $S = \{x\} \cup S'$. Given $y \in S$, then $x + y \in S'$; otherwise, by condition (b), $y = -x + (x + y) \in Z \setminus S$. Therefore, $S$ is a semigroup that is numerical because $N \setminus S \subseteq N \setminus S'$. Moreover, since $x \leq m(S') - 1 < F$, we have that $F(S) = F$.

Let us see now that $t(S) = t - 2$. On the one hand we have that $g(S) = g(S') - 1$. Thus,

$$\frac{F + t(S)}{2} \leq g(S) = g(S') - 1 = \frac{F + t}{2} - 1 = \frac{F + t - 2}{2},$$

and consequently, $t(S) \leq t - 2$. On the other hand, if $y \in PF(S') \setminus \{x, F - x\}$, then $y + z \in S'$, for every $z \in S'$ and, by condition (b), $x + y \in S$. Thus, $PF(S') \setminus \{x, F - x\} \subseteq PF(S)$ and, consequently, $t(S') - 2 = t - 2 \leq t(S)$. Thus, $t(S) = t - 2$.

From (3) it follows that $g(S) = \frac{F(S) + t(S)}{2}$; so, by Proposition 3, we obtain that $S$ is almost symmetric.

Notice that in both implications we have obtained that $PF(S') = PF(S) \cup \{x, F - x\}$, as immediate consequence. □

Observe that the set, $\cup_{i=1}^{F} \mathcal{A}(F, i)$, of almost symmetric numerical semigroups with Frobenius number $F \geq 1$ and type greater than or equal to
$t \leq F$ forms a rooted tree with root $M(F)$. Thus, using Theorem 17, we can formulate an iterative algorithm for computing the whole set $\bigcup_{i=t}^{F} \mathcal{A}(F, i)$, where the cases $1 \leq F \leq 4$ can be obtained by direct computation.

Obviously if $t = 1$, our algorithm will compute the whole set $\mathcal{A}(F)$ of almost symmetric numerical semigroups with Frobenius number $F$.

Algorithm 18. The following GAP ([7]) functions compute the whole set

$$\bigcup_{i=t}^{F} \mathcal{A}(F, i)$$

for $1 \leq t \leq F$, $F + t$ even and $F \geq 3$. The first function is nothing but the recursive step, while the second one is the core function that follows from Theorem 17. The function NumericalSemigroupByGaps from the NumericalSgps package ([5]) is required.

```gap
assemigroupswithfrobeniusnumberuptotype := function(F,t)
    local L,sg,PF,Ga,N;

    PF:=Difference([1 .. F],[F-1,1]);
    Ga:=Difference([1 .. F],[F-1]);
    Append(L,[[sg,PF,Ga]]);
    N:=[[sg,PF,Ga]];
    repeat
        N:=Concatenation(List(N, t->CallFuncList(auxiliar,t)));
        Append(L,N);
        until Length(N[1][2]) < t+2;
    return List(L, t->NumericalSemigroupByGaps(t[3]));
end;

auxiliar := function(sg,PF,Ga)
    local L,m,t,i,sg1,PF1,Ga1;
    L := []; m:=sg[1]; t:=Length(PF); F:=PF[t];
    for i in [t-1 .. m-1] do
        sg1:=Union([i],sg);
        PF1:=Difference(PF,[i,F-i]);
        Ga1:=Difference(Ga,[i]);
        if IsSubset(Ga1,Filtered(Ga1-i,j->(j>0)))
            and (Intersection(PF1+i, Ga1) = [ ]) then
                Append(L,[[sg1,PF1,Ga1]]);
            fi;
    od;
    return L;
```
end;

A much more refined implementation of our algorithm can be found at the development version site of the NumericalSgps package ([5]): https://github.com/gap-packages/numericalsgps.

Notice that algorithm computes also the set of pseudo-Frobenius numbers of every almost symmetric numerical semigroup of Frobenius number $F$ and type up to a fixed $t \geq 1$. Indeed, the key fact of Theorem [17] is that controls the set of pseudo-Frobenius numbers.

**Remark 19.** The semigroup algebra $\mathbb{Q}[S] := \bigoplus_{s \in S} \mathbb{Q} \chi^s$, a $S$–graded resolution has the form

$$0 \to \bigoplus_{j=1}^{l_{k-1}} A^{r_{k-1}j}(-b_{k-1}j) \to \ldots \to \bigoplus_{j=1}^{l_1} A^{r_1j}(-b_1j) \to A^\mathbb{P}_{\mathbb{N}} \mathbb{Q}[S] \to 0,$$

where integer $\beta_i := \sum_{j=1}^{l_j} r_{ij}$ is the rank of the ${i}$–th syzygy module of $\mathbb{Q}[S]$ and $b_{ij} \neq b_{i'j'}$, $j \neq j'$.

It is well known that $PF(S) = \{ b - \sum_{i=1}^{k} a_i \mid b \in \{b_{k-1}, \ldots, b_{k-1}l_{k-1}\} \}$ (see [9]).

On the other hand, in [11] an algorithm for the computation of the $S$–graded minimal free resolution of $\mathbb{Q}[S]$ is given. One of the main contribution in that paper is that the resolution can be computed from left to right, that is, starting from the pseudo-Frobenius number of $S$.

Therefore, our algorithms produce families of numerical semigroups for which $t = \beta_{k-1}$ is a priori known, and furthermore, for which the $S$–graded minimal free resolution of $\mathbb{Q}[S]$ can be computed starting from left to right.

### 5. Calculation time comparisons

In this section, a table with some computational results is presented. We have obtained it running GAP 4.8.6 ([7]) in a Intel(R) Core(TM) i5-2450M CPU 2.50GHz. The used implementations of our algorithms are the given above. The function

AlmostSymmetricNumericalSemigroupsWithFrobeniusNumber

is the one included in the version 1.1.8 of the NumericalSgps package ([5]).

For simplicity, we write

(A) for AlmostSymmetricNumericalSemigroupsWithFrobeniusNumber,
(B) for assemigroupswithfrobeniusnumber,
(C) for assemigroupswithfrobeniusnumberuptotype

The computation time below is expressed in seconds.

| Frobenius(S) | 13 | 14 | 15 | 20 | 25 | 30 | 40 |
|--------------|----|----|----|----|----|----|----|
| (A)          | 0.004 | 0.004 | 0.012 | 0.032 | 0.196 | 0.764 | 39.292 |
| (B)          | 0 | 0.008 | 0.008 | 0.04 | 0.172 | 0.764 | 38.924 |
| (C)          | 0 | 0 | 0.004 | 0.008 | 0.028 | 0.076 | 0.692 |
It is important to mention that the algorithm given in Section 3 is better than (C) if one just wants to compute the set \( \mathcal{A}(F, t) \) for small \( t \). For example, the function \texttt{assemigroupswithfrobeniusnumberandtype} took 0.884 seconds to compute \( \mathcal{A}(50, 4) \), whereas a truncated version of (C) took 6.632 seconds. The reason is clear, the procedure (C) needs to compute first \( \mathcal{A}(50, t) \) for every \( t \) from \( F \) to 4.

The referee proposed us the following algorithm (for simplicity we only show the case \( F \) odd):

```plaintext
assemigroupswithfrobeniusnumberuptotype2 := function(F,t)
  local F2,t2s,listaAS,s2,L,S;
  F2:=[1..Int(F/2)];
  t2s:=Combinations(F2,Int(t/2));
  listaAS:=[ ];
  for s2 in t2s do
    L:=Union(s2,F-s2);
    Append(L,[F]);
    S:=NumericalSemigroupsWithPseudoFrobeniusNumbers(L);
    Append(listaAS,S);
  od;
  return(listaAS);
end;
```

This algorithm effectively computes all AS-semigroups with a fixed Frobenius number and a given type. However, the large number of cases that must be verified makes the computation with very slow in comparison to the others. For instance, this algorithm computes the almost symmetric numerical semigroups with Frobenius number equal to 25 in around 3.5 seconds. Perhaps an optimal choice of \( t2s \) and/or a particularization of the algorithm in [3] to almost symmetric numerical semigroups will produce a faster algorithm.

**Remark 20.** We finish this paper by noting that the computational evidence supports that, for \( F \) large enough, the sequence of the cardinalities of the sets of almost symmetric of Frobenius number \( F \) and decreasing type are

1, 1, 2, 4, 7, 12, 23, 39, 67, 118, 204, 343, 592, 1001, 1693, . . .

This happens, for instance, when \( F = 55 \). This leads us to formulate the following conjecture:

- there exists \( N \) such that
  \[
  \# \mathcal{A}(F, t) = \frac{n(F-t)}{2}, \text{ for every } F \text{ and } t \geq N
  \]
  i.e. there exists \( N \) such that \( \# \mathcal{A}(F, t) \) is equal to the number of numerical semigroups with genus \( (F-t)/2 \), for every \( F \) and every \( t \geq N \).
Therefore, we could use the $\#_{\mathcal{F}}(F; t)$ to give light to the Bras-Amorós’ conjecture on the number of numerical semigroups with a given genus (see [2]).

Observe that if our conjecture is true, it will also be an interesting problem to give an upper bound for the largest $N$ in terms of $F$.

Acknowledgement. We thank the anonymous referees for their detailed suggestions and comments, which have greatly improved this article. We also thank Pedro A. García-Sánchez for his invaluable help to refine and improve the implementation of our algorithms.
