The Modified Generalized Inverted Exponential Distribution

A. M. Abouammoh*, Arwa M. Alshangiti

Department of Statistics & O. R., College of Science, King Saud University, Saudi Arabia

Abstract This paper introduces a new probability model that is the modified generalized inverted exponential distribution. This new probability model is a generalization of the well-known inverted exponential distribution as a special case. Statistical and reliability properties of the modified version are derived. Shapes for the probability density function, reliability function and failure rate function are shown with graphical illustration. The truncated distribution is studied in details. Further, estimation by the method of maximum likelihood is discussed through numerical simulation. Finally, a real data set is used where the proposed model fits better than the generalized inverted exponential distribution and the asymptotic confidence interval is given.

Keywords Modified Generalized Inverted Exponential Distribution, Generalized Inverted Exponential Distribution, Failure-rate, Mode, Reliability Function, Maximum Likelihood Estimation,

1. Introduction

The inverted Exponential distribution denoted IED ($\lambda$) has been considered by many authors; see for example Keller and Kamath (1982), Lin et al (1989) and Dey (2007). Suitable generalization of probability distribution models has the attention of many researchers and it goes back to Rogers (1893). For other applications of inverted exponential in nonextensive, relativistic statistical mechanics and quantum theory, the reader referred to Matinez et al. (2009) and references therein. The pdf of a random variable (rv) with inverted exponential distribution (IED) is given by

$$f(t) = (\frac{\lambda}{t^2}) \exp(-\lambda/t), \ t>0 \quad (1.2)$$

Abouammoh and Alshangiti (2009) introduced a generalized version of the inverted exponential distribution (GIED) which has the following probability density function

$$f(t) = \left(\frac{\lambda}{t^2}\right) \exp(-\lambda/t) \left[1 - \exp(-\lambda/t)\right]^{\alpha-1}, \ t>0, \ \lambda, \alpha > 0 \quad (1.3)$$

They have also investigated its statistical properties and its reliability functions. This distribution is capable for representing different shapes of failure rates and hence different shapes of aging criteria. Furthermore, it can be considered as the inverse of the well-known generalized exponential distribution (GED) introduced by Gupta and Kundu (1999). It is known that more general probability models can represent different variety of aging data. Proposed new models are selected for their flexible in shape and one can estimate its parameter and reliability. Here we introduced a new distribution, which contains both the GIED and the IED, respectively, and fits data much better than the GIED.

The rest of the paper is organized as follows: In section 2 the form of modified generalized exponential distribution (MGIED) is introduced. Properties of this new distribution are also discussed in this. Section 3 studies estimation of parameters and reliability function via maximum likelihood method. Also asymptotic confidence intervals are obtained in this section. Section 4 introduces a real data analysis where MGIED fits better than GIED.

2. The Proposed MGIED Model

We defined a modified generalized inverted exponential as follows; a random variable $T$ is said to have a modified generalized inverted exponential distribution and denoted by MGIED ($\lambda, \alpha, \rho$) if its pdf is given by

$$f(t) = \frac{a \lambda \rho}{1-(1-\rho)^\alpha} \left(\frac{1}{t^2}\right) t^{-\frac{\alpha}{\rho}} \left(1 - \rho e^{-\frac{\lambda}{t}}\right)^{\alpha-1}, \ t>0, \ \lambda, \alpha > 0, \ 0 < \rho \leq 1 \quad (2.1)$$

It is easy to check that (2.1) is really a pmf, and the cdf has the form

$$F(t) = \frac{1-(1-\rho e^{-\frac{\lambda}{t}})^\alpha}{1-(1-\rho)^\alpha}, \ t>0, \ \lambda, \alpha > 0, \ 0 < \rho \leq 1 \quad (2.2)$$

Figure 1 represents the pdf of the MGIED ($1, 0.5$), for $\alpha=3, 1$ and 0.2 respectively. It is obvious that the MGIED has a unimodal pdf and greater value of $\alpha$ results to more skewed pmf.
It is also noted that MGIED(λ, α, ρ) is reduced to the GIED(λ, α) distribution for ρ=1 as given in (1.1); whereas it is further reduced to the IED(λ) for α = 1.

2.1. Properties of the MGIED

In this part the reliability and statistical properties of MGIED are explored. The survival function (s.f.) of the MGIED is given by

\[ S(t) = \frac{(1 - \rho e^{-\frac{\lambda}{\alpha} t})^\alpha - (1 - \rho)^\alpha}{1 - (1 - \rho)^\alpha}, \quad t > 0 \] (2.3)

Hence, the conditional survival function is given by

\[ S(t|x) = \frac{(1 - \rho e^{-\frac{\lambda}{\alpha} t})^\alpha - (1 - \rho)^\alpha}{(1 - \rho e^{-\frac{\lambda}{\alpha} x})^\alpha - (1 - \rho)^\alpha}, \quad t > 0, x \geq 0 \] (2.4)

The failure rate of the MGIED will have the form

\[ r_t = \frac{\alpha \lambda \rho e^{-\frac{\lambda}{\alpha} t} (1 - \rho e^{-\frac{\lambda}{\alpha} t})^{\alpha-1}}{(1 - \rho e^{-\frac{\lambda}{\alpha} t})^\alpha - (1 - \rho)^\alpha} \] (2.5)

Which goes to zero as t goes to infinity. Figure 2 and 3 represents the survival function and the failure rate respectively of MGIED for different values of its shape parameter. One can note that the failure rate decreases as the shape parameter decreases and that failure rate is anti-U-shaped that is, the MGIED can represent positive and then negative aging.

Now we will discuss some statistical properties of the MGIED. The mean of the MGIED does not exist. This can be shown by noting that

\[ \mu = \frac{\lambda}{1 - (1 - \rho)^\alpha} \left( \int_0^\infty [1 - \exp(-y)]^\alpha y^{-2} dy - \int_0^\infty y^{-2} dy \right) \] (2.6)

which is a diverge integral.

The mode of f(t) is t* that satisfies the nonlinear equation

\[ \lambda (1 - \alpha \rho e^{-\frac{\lambda}{\alpha} t^*}) - 2 t^* (1 - \rho e^{-\frac{\lambda}{\alpha} t^*}) = 0 \] (2.7)

The median \( \tilde{t} \) is given by

\[ \tilde{t} = -\lambda / \ln \left( 1 - (0.5)(1 - (1 - \rho)^\alpha) \right)^{\frac{1}{\alpha}} \] (2.8)

Table 1 displays the mode and median for MGIED at different levels of parameters. From this table, one can note that the mode and median influenced by the shape parameter α. In fact, as α increases, the value of both the mean and median decreases.

| α   | λ   | ρ   | Mode | Median   |
|-----|-----|-----|------|----------|
| 0.5 | 1   | 0.5 | 0.5197 | 1.6371   |
| 3.0 | 1   | 0.5 | 0.4444 | 0.9500   |
| 10  | 1   | 0.5 | 0.3580 | 0.4971   |
| 25  | 1   | 0.5 | 0.2948 | 0.3441   |

Figure 1. The pdf of the MGIED (1, α, 0.5)

Figure 2. The survival of the GIED(1,3) and MGIED(1,3,0.5)

Figure 3. Failure rate of MGIED (1, α, 0.5)
3. Estimation and Confidence Intervals

In this section we will provide the ML method to find estimators of MGIED parameters. It is known that the estimation of the parameter can be easily utilized to estimate the reliabilities of almost all different systems configuration of components. Further, asymptotic confidence probability intervals for the estimated parameter are evaluated.

3.1. MLE of the MGIED

Let \( T_1, T_2, \ldots, T_n \) be a random sample of the MGIED having the pdf
\[
f(t) = \alpha \lambda \rho \left(1 - (1 - \rho)^\alpha \right)^{(n - 1)} \rho^{(\alpha - 1)} \left(1 - \rho - \rho e^{-\frac{t}{\rho}} \right)^{(n - 2)} t^{-1} \exp \left( - \left(1 - \rho - \rho e^{-\frac{t}{\rho}} \right) \right) t^{(n - 1)}, \quad t > 0, 1 \leq n, \quad \alpha, \lambda > 0, \quad 0 < \rho \leq 1
\]
and let the vector of parameters \( \theta = (\lambda, \alpha, \rho) \), the likelihood function will be
\[
L(\theta) = \left( \frac{\alpha \lambda \rho}{1 - (1 - \rho)^\alpha} \right)^n \left(\prod_{i=1}^{n} (1 - \rho e^{-\frac{T_i}{\rho}})^{\alpha - 1}\right) \left(\prod_{i=1}^{n} T_i^{\alpha - 1} \right) \left( e^{-\frac{\lambda}{\rho} + \sum_{i=1}^{n} T_i} \right)
\]
And hence
\[
1 \ln L(\theta) = n \ln a \lambda \rho - n \ln (1 - (1 - \rho)^\alpha) - 2 \sum_{i=1}^{n} \ln t_i - \lambda \sum_{i=1}^{n} T_i + (\alpha - 1) \sum_{i=1}^{n} \ln (1 - \rho e^{-\frac{t_i}{\rho}})
\]
So that the normal equations are given by
\[
\frac{\partial \ln L(\theta)}{\partial \alpha} = \frac{n}{\alpha} + \frac{n(1 - \rho)^\alpha \ln (1 - \rho) + \sum_{i=1}^{n} \ln (1 - \rho e^{-\frac{T_i}{\rho}})}{1 - (1 - \rho)^\alpha} = 0 \quad (3.1)
\]
\[
\frac{\partial \ln L(\theta)}{\partial \lambda} = \frac{n}{\lambda} + (\alpha - 1) \sum_{i=1}^{n} \rho (1/T_i) e^{-\frac{t_i}{\rho}} - \sum_{i=1}^{n} 1/t_i = 0 \quad (3.2)
\]
\[
\frac{\partial \ln L(\theta)}{\partial \rho} = \frac{n}{\rho} - \frac{n(1 - \rho)^\alpha - 1}{1 - (1 - \rho)^\alpha} - (\alpha - 1) \sum_{i=1}^{n} \frac{e^{-\frac{t_i}{\rho}}}{1 - (1 - \rho e^{-\frac{t_i}{\rho}})} = 0 \quad (3.3)
\]

Two cases are considered here for illustration purpose, one when all the parameters are unknown and the other when \( \rho \) is at least known. Other different cases can be similarly considered.

- **Case I**: All the three parameters are unknown.

In this case the equations (3.1), (3.2) and (3.3) need to be solved numerically since there are no explicit solutions. We will consider here the estimation for a sample of size \( n=100 \) and take the estimates averaged over 1000 runs. Without loss of generality the population value considered here for \( \lambda \) is one. We take two cases, the first if we change the value of \( \alpha \) and the second if we change the value of \( \rho \).

Tables 3 and 4 represent the MLEs of the parameters and s.f. (\( \hat{S}_{MLE} \)) at \( t=1 \) respectively at different levels of \( \alpha \), the population value of \( \rho \) taken here to be 0.8. From these two tables and except for \( \alpha=1 \) which represents the IED, one can observe the following:
- The mean square error (MSE) of \( \lambda \) decreases as the value of \( \alpha \) increases.
- The MSE of \( \alpha \) and the bias increases as the value of \( \alpha \) increases.
- The MSE of \( \rho \) and the absolute value of bias decreases as the value of \( \alpha \) increases.
- The value of the estimated s.f decreases and the MSE increases as the value of \( \alpha \) increases.

The above notes may indicate that the estimation of \( \lambda \) and \( \rho \) is better for large values of \( \alpha \) while the estimation of \( \alpha \) and s.f is better for small values of \( \alpha \). From the tables also one can note that \( \alpha \) and \( \lambda \) tend to be over-estimated while \( \rho \) tends to be underestimated and so does the s.f. especially for larger values of \( \alpha \).

Tables 5 and 6 represent the MLEs of the parameters and s.f. (\( \hat{S}_{MLE} \)) at \( t=1 \) respectively at different levels of \( \rho \), the population value of \( \alpha \) taken here to be 2 and the different values of \( \alpha \) are 0.2, 0.4, 0.6 and 0.8. We observe the following notes from these tables:
- The estimation of \( \rho \) and \( \lambda \) is better for moderate values of \( \alpha \) than small and large values.
- The estimation of \( \alpha \) is better for small values of \( \rho \).
- The estimation of s.f is better for small values of \( \rho \).

- **Case II**: \( \rho=\rho_0=0 \) is known.

In this case we fix the value of \( \rho \) at \( \rho_0=0.8 \), here we only need to solve (3.1) and (3.2) numerically. Different samples from MGIED are generated at the sample sizes 15, 20, 30, 50 and 100, we take the estimates as the average of 1000 runs, and the population value of \( \lambda \) is taken here to be one. The different values of \( \alpha \) considered are 0.5, 1, 1.5, 2, 2.5 and 3. Tables (7), (8) and (9) represent the MLEs of \( \alpha \), \( \lambda \) and the s.f. (\( \hat{S}_{MLE} \)) at \( t=0.5 \). We have the following comments on these tables:
- The MSE and the bias for the estimates of \( \alpha \) and \( \lambda \) decrease as the sample size increases.
- The estimation of \( \alpha \) is better for small values of \( \alpha \), while the estimation of \( \lambda \) is better for large values of \( \alpha \).
- The estimated s.f increases as the value of \( \alpha \) increases.
- There is overestimation for both \( \alpha \) and \( \lambda \), while there is under estimation for s.f.

3.2. Asymptotic Confidence Intervals

Here we derive the approximate CIs of the parameters that based on the asymptotic normal distribution of MLEs, since the exact distributions of the MLE of these parameters are unknown because they don’t have closed forms.

The 1st derivative of the log likelihood function of MGIED is given by (3.1), (3.2), (3.3). The 2nd derivative is obtained as follows.
\[ \frac{\partial^2}{\partial \alpha^2} \ln l(\theta) = \frac{n}{\alpha^2} + \frac{n[\ln(1-\rho)]^2 (1-\rho)}{[1-(1-\rho)\alpha]^2} \] (3.4)

\[ \frac{\partial^2}{\partial \lambda^2} \ln l(\theta) = \frac{-n}{\lambda^2} - (\alpha - 1) \rho \sum_{i=1}^{n} t_i^2 (1-\rho) e^{-(\lambda t_i)\rho} \] (3.5)

\[ \frac{\partial^2}{\partial \alpha \partial \lambda} \ln l(\theta) = \rho \sum_{i=1}^{n} t_i (1-\rho) e^{-(\lambda t_i)\rho} \] (3.6)

\[ \frac{\partial^2}{\partial \alpha \partial \rho} \ln l(\theta) = \frac{n(1-\rho)^{\alpha-1}[(1-\rho)^\alpha - \alpha \ln(1-\rho) - 1]}{[1-(1-\rho)^\alpha]^2} \sum_{i=1}^{n} e^{-(\lambda t_i)\rho} \] (3.7)

\[ \frac{\partial^2}{\partial \lambda \partial \rho} \ln l(\theta) = (\alpha - 1) \sum_{i=1}^{n} t_i (1-\rho) e^{-(\lambda t_i)\rho} \] (3.8)

The information matrix would be

\[
I(\theta) = \begin{pmatrix}
-\frac{\partial^2\ln l(\theta)}{\partial \alpha^2} & -\frac{\partial^2\ln l(\theta)}{\partial \alpha \partial \lambda} & -\frac{\partial^2\ln l(\theta)}{\partial \alpha \partial \rho} \\
-\frac{\partial^2\ln l(\theta)}{\partial \alpha \partial \lambda} & -\frac{\partial^2\ln l(\theta)}{\partial \lambda^2} & -\frac{\partial^2\ln l(\theta)}{\partial \lambda \partial \rho} \\
-\frac{\partial^2\ln l(\theta)}{\partial \alpha \partial \rho} & -\frac{\partial^2\ln l(\theta)}{\partial \lambda \partial \rho} & -\frac{\partial^2\ln l(\theta)}{\partial \rho^2}
\end{pmatrix}
\] (3.9)

The approximate (1-\delta) 100% CIs for \( \alpha, \lambda, \) and \( \rho \) are:

\[ \hat{\alpha} \pm \xi_{\delta/2} \sqrt{V(\hat{\alpha})}, \quad \hat{\lambda} \pm \xi_{\delta/2} \sqrt{V(\hat{\lambda})}, \quad \hat{\rho} \pm \xi_{\delta/2} \sqrt{V(\hat{\rho})} \]

respectively, where \( V(\hat{\alpha}), V(\hat{\lambda}), \) and \( V(\hat{\rho}) \) are the variances of \( \hat{\alpha}, \hat{\lambda}, \) and \( \hat{\rho} \), which are given by the diagonal elements of \( I^{-1}(\theta) \), and \( \xi_{\delta/2} \) is the upper (\( \delta/2 \)) percentile of the standard normal distribution.

4. Data Analysis

Dumonceaux and Antle (1973) used a data which represents the maximum flood level (in millions of cubic feet per second) of the Susquehanna River at Harrisburg, Pennsylvania over 20 four-year periods (1890-1969) as follows

\[ 0.645, 0.613, 0.315, 0.449, 0.297, 0.402, 0.379, 0.423, 0.379, 0.324, 0.269, 0.740, 0.418, 0.412, 0.494, 0.416, 0.338, 0.392, 0.484, 0.265 \]

Here we want to test if this data comes from MGIED or GIED using the likelihood ratio test, which is as follows

- \( H_0: \rho = 1 \) (GIED)
- \( H_1: \rho \neq 1 \) (MGIED)

The results of this test are presented in the following table:

| \( \hat{\lambda} \) | \( \hat{\alpha} \) | \( \hat{\rho} \) | ln l(\( \theta \)) | X2 | p-value |
|-----------------|-----------------|-----------------|-----------------|-----|---------|
| 1.652           | 38.476          | ------          | 15.516          |
| 0.278           | 3.818           | 0.0248          | 109.239         | 1.438 \times 10^{-25} |

Note that the value of \( \chi^2 \) is greater than the critical value of chi-square with one degree of freedom; also the very small p-value indicates that this data fits MGIED much better than GIED.

If we want to find the asymptotic CIs for the parameters of the data in this example as it comes from MGIED, we obtain the observed information matrix as

\[
I(\theta) = \begin{pmatrix}
0.001 & -0.611 & -188.384 \\
-0.611 & 262.635 & -70.232 \\
-188.384 & -70.232 & 9.735
\end{pmatrix}
\]

and the variance covariance matrix \( I^{-1}(\theta) \)

\[
I^{-1}(\theta) = \begin{pmatrix}
0.00025 & -0.00142 & -0.00053 \\
-0.00142 & 0.00038 & -0.000012 \\
-0.00053 & -0.000012 & 1.036 \times 10^{-8}
\end{pmatrix}
\]

The 95% CIs for \( \alpha, \lambda, \) and \( \rho \) are given by [3.787, 3.849], [0.157, 0.399] and [0.0246, 0.0250] respectively.

The Q-Q plot of the flood level data is represented in figure 4 confirms our result, where the percentile \( p \), is taken to be (i-0.5)/n.

5. Conclusions

In this paper, we introduced a new distribution that can serve better than existing well known models. The reliability and probability properties are discussed. Estimation of parameters and survival function is conducted. Finally, a real set of data is fit and is shown to be appropriate.
