Stochastic Ricci Flow on Compact Surfaces

Julien Dubédat* and Hao Shen†

April 25, 2019

Abstract

In this paper we introduce the stochastic Ricci flow (SRF) in two spatial dimensions. The flow is symmetric with respect to a measure induced by Liouville Conformal Field Theory. Using the theory of Dirichlet forms, we construct a weak solution to the associated equation of the area measure on a flat torus, in the full “$L^1$ regime” $\sigma < \sigma_{L^1} = 2\sqrt{\pi}$ where $\sigma$ is the noise strength. We also describe the main necessary modifications needed for the SRF on general compact surfaces, and list some open questions.

1 Introduction

The Ricci flow, introduced by Hamilton [Ham88], is an intrinsic evolution of a Riemannian metric $g = g(t)$ on a fixed smooth manifold:

$$\partial_t g = -2R_g$$

where $R_g$ is the Ricci curvature of $g$. Assuming that the manifold is a closed (compact oriented) Riemann surface, we will be interested in a normalized version of the flow:

$$\partial_t g = -2R_g - 2\lambda g$$ \hspace{1cm} (1.1)

The real number $\lambda$ plays the role of a normalization constant: when $\lambda$ is chosen to be the average Gauss curvature, the flow preserves total area, and converges to the constant curvature metric as proved by [Ham88, Cho91, OPSS88]. Remark that, with a simple time change $t' = at$ and change of unknown $g'(t) = g(t)e^{bt}$, one gets a dynamic of the form $\partial_t g = -\sigma^2 R_g - bg$ for arbitrary $\sigma^2 > 0$ and $b \in \mathbb{R}$. Moreover, classification results in Riemannian geometry show that, besides $g$ itself, $R_g$ is the only tensor of the same tensor type as $g$ which is intrinsic (i.e. does not depend on coordinate or other choices) and constructed from derivatives of $g$ up to order 2. It follows that, up to normalization, the Ricci flow (1.1) is the only intrinsic parabolic (deterministic) evolution of the metric. In the present article, we are concerned with constructing intrinsic stochastic evolutions of the metric.

Recall the following facts. Let $g_0$ be a metric on a closed Riemann surface. We consider metrics obtained by Weyl scaling $g = e^{2\phi}g_0$, where the function $\phi$ is the conformal factor. The Ricci curvature tensor $R_g$, the Gauss curvature $K_g$, the Laplacian $\Delta_g$ and the area form $\omega_g$ for $g$ then satisfy

$$R_g = R_0 - \Delta_0 \phi g_0 , \quad K_g = e^{-2\phi}(K_0 - \Delta_0 \phi) , \quad \Delta_g = e^{-2\phi} \Delta_0 , \quad \omega_g = e^{2\phi} \omega_0 ,$$ \hspace{1cm} (1.2)

where $R_0$, $\Delta_0$ and $\omega_0$ are respectively the Ricci curvature, the Laplacian and area form for $g_0$. Since the dimension is two, the scalar curvature (the trace of the Ricci tensor w.r.t. the metric) equals twice the Gauss curvature, and one always has $R_g = K_g g$. An important property of the 2d Ricci flow is that the metric evolves within a conformal class, namely if the initial condition has the above form, then $g(t) = e^{2\phi(t)}g_0$ for all $t > 0$, so that the equation (1.1) can be written in terms of the conformal factor in the following equivalent forms:

$$\partial_t \phi = -K_g - \lambda = \Delta_g \phi - e^{-2\phi} K_0 - \lambda$$

$$= e^{-2\phi} \Delta_0 \phi - e^{-2\phi} K_0 - \lambda .$$ \hspace{1cm} (1.3)

To motivate our stochastic version of the two-dimensional Ricci flow, as well as its connection to the Liouville Conformal Field Theory (LCFT), we recall that String

\footnote{In this article the Laplacian is just the trace of the Hessian on functions, without a negative sign.}
Theory is concerned with surfaces with varying metrics \( g \), and a central quantity is the ("\( \zeta \)-regularized") determinant of Laplacian formally denoted by \( \det' \Delta_g \). This a spectral invariant, i.e. can be computed from the spectrum of \( \Delta_g \) (which is discrete and satisfies Weyl asymptotics). Osgood-Phillips-Sarnak \cite{OPS88} provided an important perspective on the uniformization theorem: in \cite[Theorem 1]{OPS88} they proved that among all metrics in a given conformal class and of given area, the constant curvature metric (which exists and is unique up to isometry) has maximum determinant \( \det' \Delta_g \).

They also showed that \cite[Theorem 2.A]{OPS88} when the Euler characteristic is non-positive, the Ricci flow can be realized as a gradient flow, as we now explain.

On the Riemann surface \( \Sigma \), the celebrated Polyakov \cite{Pol81} anomaly formula (see e.g. Section 1 of \cite{OPS88}) for the variation of the quantity \( \log \det' \Delta_g \) under conformal change \( g = e^{2\phi} g_0 \) reads:

\[
\log \det' \Delta_g - \log \det' \Delta_0 = -\frac{1}{12\pi} \int_\Sigma |\nabla g_0 \phi|^2 \omega_0 - \frac{1}{6\pi} \int_\Sigma K_0 \phi \omega_0 + \log \frac{V_g}{V_0} \tag{1.4}
\]

where \( V_0, V_g \) are areas of \( g_0 \) and \( g \), i.e. \( V_g = \int_\Sigma \omega_g = \int_\Sigma e^{2\phi} \omega_0 \); and \( K_0 \) is the Gauss curvature of \( g_0 \). Define a "potential" for \( \lambda \in \mathbb{R} \)

\[
V(g) = - \log \det' \Delta_g + \log V_g + \frac{\lambda}{12\pi} V_g .
\]

By (1.4) we see that \( 6\pi (V(g) - V(g_0)) \) is essentially the (classical) Liouville action \( S(\phi) \) up to a constant

\[
6\pi (V(g) - V(g_0)) + \frac{\lambda}{2} V_0 = S(g_0, \phi) := \int_\Sigma \left( \frac{1}{2} |\nabla g_0 \phi|^2 + K_0 \phi + \frac{\lambda}{2} e^{2\phi} \right) \omega_0 \tag{1.5}
\]

which gives a concrete formula for the action. By a simple change of variables – see Section 1.2 below – this is exactly the same as the probabilists’ convention of definition of the classical Liouville action, up to an overall constant \( \frac{2\pi}{\lambda} \).

The Ricci flow (1.3) turns out to be a gradient flow of \( S(g_0, \phi) \) (and thus \( 6\pi V(\phi) \)) given in (1.5) with respect to the a formal Riemannian structure on the infinite-dimensional space of metrics on \( \Sigma \) in a fixed conformal class, where the “tangent space” at \( g \) is equipped with the intrinsic inner product \( L^2(\omega_g) \) (rather than the 'flat' inner product \( L^2(\omega_0)! \)). Here, the metric \( L^2(\omega_g) \) is defined such that for a “tangent” vector \( \delta \phi \) at a Riemannian metric \( g \),

\[
\|\delta \phi\|_{L^2(\omega_g)}^2 = \int_\Lambda (\delta \phi)^2 \omega_g . \tag{1.6}
\]

Indeed, consider a perturbation \( g + \delta g = e^{2\delta \phi} g \); then by (1.5) and (1.2)

\[
\delta S(g_0, \phi) = \int_\Sigma (K_0 - \Delta_0 \phi) \delta \phi \omega_0 + \lambda \int_\Sigma \delta \phi \omega_g = \langle K_g + \lambda, \delta \phi \rangle_{L^2(\omega_g)}
\]

so that the gradient flow associated to \( S(g_0, \phi) = 6\pi V \) is indeed the Ricci flow (1.3).
In the sequel we write $\Delta = \Delta_0$. Note that the gradient flow of $S(g_0, \phi)$ with respect to the “flat” metric $L^2(\omega_0)$ would be

$$\partial_t \phi = \Delta \phi - K_0 - \lambda e^{2\phi},$$

and a stochastic version of this equation (namely, this equation plus the space-time white noise) was studied in [Gar18] recently, and is called a dynamical Liouville equation therein.

In view of this, the natural and intrinsic noise that we would like to add to equation (1.3) should then be a noise which, in the spatial direction, is “white” with respect to $L^2(\omega_0)$. In fact if $\zeta_0$ is a spatial white noise w.r.t. $L^2(\omega_0)$, and $\phi$ is a smooth conformal factor, then $\zeta_g := e^{-\phi} \zeta_0$ is white with respect to the metric $L^2(\omega_0)$, namely, by (1.2),

$$E \left[ \left( \int_{\Lambda} f \zeta_g \omega_g \right)^2 \right] = E \left[ \left( \int_{\Lambda} f \zeta_0 e^\phi \omega_0 \right)^2 \right] = \int_{\Lambda} f^2 e^{2\phi} \omega_0 = \int_{\Lambda} f^2 \omega_g. \quad (1.7)$$

In this paper we focus first on a flat two-dimensional torus $\Sigma = \Lambda = \mathbb{C}/(\mathbb{Z} + \tau \mathbb{Z})$, $\Im(\tau) > 0$. We will briefly discuss the case of compact surfaces in Section 4.1, and we will see there that while on the torus the stochastic Ricci flow is the classical Ricci flow (in terms of $\phi$) plus a noise that is white with respect to the metric $g$, there are complications when the reference is not flat.

Let $g_0$ be a flat metric on $\Lambda$ such that $K_0 = 0$. The stochastic Ricci flow (SRF) that we study in this paper is then formally given by

$$\partial_t g = -2R_g - 2\lambda g + 2\sigma \xi_g g,$$

where $\xi_g := e^{-\phi} \xi_0$, or (again formally) in terms of the conformal factor

$$\partial_t \phi = \Delta_g \phi - \lambda + \sigma \xi_g \phi = e^{-2\phi} \Delta \phi - \lambda + \sigma e^{-\phi} \xi_0, \quad (1.8)$$

where $\sigma \in \mathbb{R}$ and $\xi_0$ is the space-time white noise w.r.t. the Euclidean metric $g_0$. Equation (1.8) is a nonlinear version of the stochastic heat equation (SHE)

$$\partial_t \phi = \Delta \phi + \sigma \xi_0$$

whose invariant measure is the Gaussian Free Field (GFF) with covariance operator $\frac{\sigma^2}{2}(-\Delta)^{-1}$. In particular $\phi$ has negative regularity.

Let us point out that, beyond the usual “flat” SHE, one can consider a SHE with respect to a fixed smooth metric $\hat{g} = e^{2\phi} g_0$; it reads

$$\partial_t \phi = \Delta_{\hat{g}} \phi + \sigma \xi_{\hat{g}} = e^{-2\phi} \Delta_0 \phi + \sigma e^{-\phi} \xi_0. \quad (1.9)$$

For any fixed, smooth $\tilde{\phi}$, the invariant measure is the same GFF. In view of this, it is natural to expect that a solution of (1.8) has the (negative) regularity of a GFF, and thus all nonlinearities have to be regularized.

In (1.8), setting $\sigma = 0$ recovers the Ricci flow (1.3); setting $\lambda = 0$, $\tilde{\phi} = \sigma^{-1}\phi$, starting from $\phi_0 \equiv 0$, and formally taking $\sigma \searrow 0$ (i.e. perturbation around the constant flat solution) gives the Stochastic Heat Equation.
By formally taking time derivative on $\omega_g = e^{2\phi} \omega_0$, the evolution for the area form $\omega_g(t)$ is (again formally) given by

$$\partial_t \omega_g(t) = 2\Delta \phi(t) \omega_0 - 2\lambda \omega_g(t) + 2\sigma \xi_g \omega_g(t). \quad (1.10)$$

Note that the r.h.s. has $\phi$ explicitly showing up. Heuristically this is understood as the conformal factor $\phi$ and the area form $\omega_g = e^{2\phi} \omega_0$ mutually determine each other. The precise meaning of this mutual determination is discussed below, see the “inversion” property of GMC (as proved by [BSS14]) in Section 1.1.

### 1.1 Gaussian multiplicative chaos (GMC)

The previous discussion suggests that we consider a process of measures $\omega_g(t) = e^{2\phi(t)} \omega_0$, where $\phi$ looks like a GFF. Such Gaussian multiplicative chaos (GMC) or Liouville measures have been studied extensively, going back to Høegh-Krohn [HeK71]; we refer to the survey [RV14] and references therein. We list below some basic properties we will need later. We focus on the GFF context relevant to us, although most properties below hold in greater generality (log-correlated fields). See e.g. [Dub09] and references therein for general background on the GFF.

#### Existence and construction

Let $X$ denote a Gaussian Free Field with Dirichlet conditions in a domain $D \subset \mathbb{C}$; it is a centered Gaussian field with covariance given by the Dirichlet Green function:

$$\mathbb{E}(X(z)X(w)) = 2\pi (-\Delta)^{-1}(z,w) = -\log |z-w| + R(z,w)$$

where $R$ is smooth near the diagonal. It is a random distribution (in the sense of Schwartz) and can be realized as a random element of a negative index Sobolev space $H_{loc}^{-s}(D)$, $s > 0$, in the abstract Wiener space formalism.

For $\varepsilon > 0$ (and away from the boundary), one can consider the circle average process $X_\varepsilon(z) = \int X(z + \varepsilon e^{i\theta}) \frac{d\theta}{2\pi}$. This can be realized as a continuous process, as is easily seen by Kolmogorov’s continuity criterion; each $X_\varepsilon$ is measurable w.r.t. $X$. Then one can consider a positive measure on $D$

$$M_\varepsilon(X) = \varepsilon^2 \exp(\gamma X_\varepsilon(x))\omega_0(dx) \quad (1.11)$$

where $\gamma$ is a positive parameter and $\omega_0$ is the Lebesgue measure.

Then [DS11], if $0 < \gamma < 2$, the sequence $(M_\varepsilon)$ converges almost surely in the topology of weak convergence to a positive measure $M_X$, as $\varepsilon$ goes to zero along a suitable fixed sequence. The random measure $M_X$ can thus naturally be thought of as a regularized $e^{\gamma X}\omega_0$. It is nonatomic and gives a.s. positive mass to any nonempty open set, and a.s. finite mass to any compact $K \subset D$; it is thus a random element of the space $\mathcal{M}(D)$ of Radon measures on $D$.

It can be shown that $M_X$ is a.s. supported on $\{z \in D : \lim_{\varepsilon \downarrow 0} \frac{X_\varepsilon(z)}{\log |\varepsilon|} = \gamma\}$ and consequently is a.s. absolutely singular w.r.t. Lebesgue measure.
If \( \gamma \in (0, \sqrt{2}) \) and \( f \) is a test function, \( \int f dM_X \) is a square-integrable; this is the so-called \( L^2 \) regime and leads to simpler arguments; however the results below hold in the full range \( \gamma \in (0, 2) \).

Other natural approximation schemes (convolution of \( X \) with the heat kernel, or a smooth compactly supported kernel) are possible, and consistent \([Sha16]\).

**Basic properties.** A few important properties follow immediately from the construction.

1. **Locality.** If \( U \subset V \subset D \), then the restriction of \( M_X \) to \( U \) is measurable w.r.t. the restriction of \( X \) to \( V \) (this refines the measurability of \( X \mapsto M_X \)).

2. **Equivariance.** With the previous notation, the mapping \( X|_V \mapsto (M_X)|_U \) does not depend on \( D \) and is equivariant w.r.t. Euclidean isometries.

3. **Shift.** If \( f \in C_0^1(\mathcal{V}) \) is fixed, \( dM_{f+X} = e^{\gamma f} dM_X \) a.s. (note under these assumptions, the law of \( f + X \) and that of \( X \) are mutually absolutely continuous).

Note that shift covariance is central to the approach of \([Sha16]\); the condition \( f \in C_0^1 \) can be relaxed to \( f \in H^1 \) which is the Cameron-Martin space. An important additional property is scale (more generally, conformal) covariance.

**Inversion.** We previously listed properties of the mapping \( X \mapsto M_X \), which is defined a.e. on an abstract Wiener space. It will be convenient for our purposes to consider the a.e. defined inverse map \( M_X \mapsto X \), constructed by Berestycki-Sheffield-Sun in \([BSS14]\). More precisely, if \( (X, M_X) \in H^s_{\text{loc}}(D) \times \mathcal{M}(D) \) are coupled as above, then \( X \) is measurable w.r.t. \( M_X \). This shows the existence of an a.e. inverse mapping \( M_X \mapsto X \), which is a.e. defined (with respect to the induced measure on the second marginal \( \mathcal{M}(D) \)).

From the explicit construction of \([BSS14]\), it is clear that this inverse mapping is also local, equivariant, and compatible with shift.

**Conventions.** In our “geometer’s convention” (coming from the Ricci flow) we would like to consider a Gaussian free field \( \phi \) with covariance operator \( \sigma^2 (-\Delta)^{-1} \); in order to match with the above standard conventions for Liouville measures, let

\[
\phi = \frac{\gamma}{2} X \quad \text{and} \quad \sigma = \sqrt{\pi \gamma},
\]

so that

\[
e^{2\phi} = e^{\gamma X}.
\]

With our convention, \( M_\varepsilon = e^{2\phi - 2\varepsilon \phi^2} \omega_0 \) converges to the limit denoted by \( M = M_\phi = :e^{2\phi} \omega_0: \). The a.e. correspondence \( \phi \leftrightarrow M_\phi \) is local and equivariant in the previous sense; the compatibility with shift simply reads

\[
dM_{f+\phi} = e^{2f} dM_\phi
\]

for a.e. \( \phi \), where \( f \) is a fixed \( H^1 \) function.
Remark that the locality of the correspondence shows that it also holds for a field \( \phi \) on a surface whose restriction to small balls is absolutely continuous w.r.t. a GFF there; in particular for \( \phi \) a GFF on a flat torus.

The "\( L^2 \) regime" such that \( M(f) \) for a smooth test function \( f \) has finite second moment as well the "\( L^1 \) regime" all the way to which \( M \) obtained this way is nontrivial are respectively

\[
\sigma < \sigma_{L^2} = \sqrt{2\pi} \quad \sigma < \sigma_{L^1} = 2\sqrt{\pi}
\]

(which corresponds to the well-known \( \gamma < \gamma_{L^2} = \sqrt{2} \) and \( \gamma < \gamma_{L^1} = 2 \)).

1.2 Liouville conformal field theory

Closely related with GMC is the Liouville CFT measure on the space of fields \( X \) over a Riemann surface with a fixed smooth reference metric \( g_0 \) and volume form \( \omega_0 \), which is given by

\[
Z^{-1} e^{-S(X)} DX
\]

where \( Z \) is a normalization factor, \( K_0 \) is the Gauss curvature of \( g_0 \). The measure (with suitable insertions of vertex operators, see below) has been rigorously constructed by [DKRV16] (on the sphere, see [Kup16a] for a review), and [DRV16] on the complex tori, and [GRV16b] (genus \( \geq 2 \)); see also [HRV18] (on disk) and [Rem18] (on annulus). The parameter \( \mu > 0 \) is the analogue of a "cosmological constant" in two dimensional gravity and \( Q \) is a real parameter. For the particular value \( Q = \frac{2}{\gamma} \) the action functional \( S \) is classically conformally covariant. In the quantized theory \( Q \) has the renormalized value \( Q = \frac{2}{\gamma} + \frac{\gamma}{\pi} \) such that the random measure \( e^{\gamma X} \) is invariant in law under change of reference measure (within a conformal class). Note that if we focus on a torus \( \Lambda \) with flat metric \( g_0 \) then the necessary correction term \( QRg_0 X \) is hidden.

We remark that when the genus \( g \leq 1 \), the measure \( e^{-S(X)} DX \) is not really normalizable (i.e. \( Z \) is not well-defined) since the integral will diverge as the value of \( X \) tends to \( -\infty \), unless suitable vertex operators (see below) are inserted. However, in this paper where we work with torus \( g = 1 \), we will not consider insertions and thus will not normalize the measure. Rather, we will view it as a \( \sigma \)-finite measure, see (2.30) and Lemma 2.5 below.

**Conventions.** The action \( S(g_0, \phi) \) in (1.5) and the stochastic Ricci flow (1.8) depends on two parameters \( (\lambda, \sigma) \), and the standard conventions for the Liouville CFT action \( S(X) \) in the probability literature depends on two parameters \( (\mu, \gamma) \). To match the two conventions

\[
(\phi, \lambda, \sigma) \leftrightarrow (X, \mu, \gamma)
\]

besides the relations (1.12), we further set \( \lambda = \pi \mu \gamma^2 \), and we summarize all these relations here:

\[
\phi = \frac{\gamma}{2} X \quad , \quad \sigma = \sqrt{\pi \gamma} \quad , \quad \lambda = \pi \mu \gamma^2 \quad . \quad (1.14)
\]
In this way we have
\[ \frac{\pi \gamma^2}{2} \cdot \frac{1}{4\pi} \int_{\Sigma} \left( |\nabla X|^2 + 2K_0 QX + 4\pi \mu e^{\gamma X} \right) \omega_0 = \int_{\Sigma} \left( \frac{1}{2} |\nabla \phi|^2 + K_0 \phi + \frac{\lambda}{2} e^{2\phi} \right) \omega_0 \]
where \( Q = \frac{2}{\gamma} \).

**Invariance.** The dynamic (1.8) should be symmetric with respect to the measure induced by Liouville CFT (1.15), see Remark 3.5. Thus the dynamic (1.8) can be viewed as a natural stochastic quantization of the Liouville CFT; constructing such stochastic quantization dynamics have drawn much attention in the recent years [Hai14, CCL13, Kup16b, HS16, CHS18, Gar18] and references therein.

**Insertions.** Of great interest in Liouville CFT is the insertions of vertex operators
\[ Z^{-1} \int \prod_{i=1}^{n} e^{\alpha_i X(x_i)} e^{-S(X)} DX \]
for \( n \) fixed points \( x_i \) on the Riemann surface and \( n \) real parameters \( \alpha_i \) satisfying the so called Seiberg bounds: \( \sum_{i=1}^{n} \alpha_i > 2Q \) and \( \alpha_i < Q \) for each \( i \). The corresponding stochastic dynamic – by a similar calculation as in the proof of Theorem 2.6 and similar argument as in Remark 3.5 – would be a formal equation of the following form
\[ \partial_t g = -2R_g - 2\lambda g + 2\sigma \xi g + \sum_{i=1}^{n} \alpha_i \delta_{x_i}, \]
where each \( \delta_{x_i} \) is a Dirac mass at \( x_i \); or formally in terms of the area form
\[ \partial_t \omega_g(t) = 2\Delta \phi(t) \omega_0 - 2\lambda \omega_g(t) + 2\sigma \xi_g \omega_g(t) + \sum_{i=1}^{n} \alpha_i \delta_{x_i}. \]

When \( \sigma = 0 \) (deterministic case) such equations appear in the context of metrics with conical singularities (see for instance [PSSW14]; see Section 4.2 for further discussions).

### 1.3 Main result

Our main result is in a construction of weak solution to the equation (1.10) for the area measure \( \omega \). First, we need to formulate a notion of weak solution. By the calculation (1.7), we expect that given a suitable test function \( f \), one should have the following one-dimensional projected stochastic equation
\[ d \int_{\Lambda} f \omega_g = 2 \left( \int_{\Lambda} f \Delta \phi \omega_0 - \lambda \int_{\Lambda} f \omega_g \right) dt + 2\sigma \left( \int_{\Lambda} f^2 \omega_g \right)^{\frac{1}{2}} d\beta_t. \]

Here \( (\beta_t) \) is a one-dimensional standard Brownian motion.
To formulate our result, let $\mathcal{M}_1(\Lambda)$ be the space of Borel probability measures on $\Lambda$ and $\mathcal{M}(\Lambda)$ be the space of finite positive Borel measures, equipped with the metrizable topology of weak (vague) convergence. Let

$$\mathcal{X} := \mathcal{M}(\Lambda) \setminus \{0\}.$$ 

For $A \in \mathcal{X}$ and a function $f$ on $\Lambda$ we write by $A(f)$ the integral of $f$ with respect to the measure $A$. We write $A(\Lambda) = A(1)$. Note that $\mathcal{X}$ is locally compact and $\mathcal{X}$ is homeomorphic to $\mathcal{M}_1(\Lambda) \times (0, \infty)$ via $A \mapsto (A/V, V)$, where $V = A(\Lambda)$ is the total measure of the torus $\Lambda$ under the measure $A \in \mathcal{X}$. For an area form $\omega$ we view it as a measure and write $\omega(f) := \int f \omega$.

**Theorem 1.1.** For $\sigma < \sigma_{L_1} = 2\sqrt{\pi}$, there exists a Markov diffusion process $A = \{\Omega, \mathcal{F}, (A_t)_{t \geq 0}, (P_z)_{z \in \mathcal{X}}\}$ on the space $\mathcal{X}$, such that for any smooth function $f$ and quasi-every $z \in \mathcal{X}$, $A_t(f)$ satisfies the following SDE

$$dA_t(f) = 2\left(\omega_0(f \Delta \phi_t) - \lambda A_t(f)\right)dt + 2\sigma \left(A_t(f^2)\right)^{\frac{3}{2}} d\beta^f_t, \quad A_0(f) = z(f), \quad (1.17)$$

where $\forall t > 0, \phi_t = M^{-1}A_t$ a.s. and $\beta^f$ is a one-dimensional standard Brownian motion.

**Remark 1.2.** A next goal would be to construct a (coupled) process $(\phi_t, A_t)$ where the component $\phi$ takes values in the space of Schwartz distributions $H^{-\epsilon}(\Lambda)$ and the component $A$ takes values in the space of Borel measures, such that for each $t > 0$, $\phi_t$ is absolutely continuous w.r.t. the Gaussian free field, and the process $(A_t)$ is such that $A_t = e^{2\phi_t} \omega_0$: with the one-dimensional projection (1.16). See Section 5 for further discussions.

We will construct a weak solution using the theory of infinite-dimensional Dirichlet forms. This is a general machinery to construct weak solutions of stochastic equations which have explicit invariant (or at least symmetrizing) measures. We will frequently refer to the book [FOT11] when implementing this formalism. Among many applications of Dirichlet forms in constructing weak solutions of stochastic equations, we mention another instance of stochastic version of a geometric flow by [RWZZ17, CWZZ18] who considered a manifold-valued stochastic heat equations (and the strong solution has been also constructed, by [BGHZ19]). We also remark that the theory of Dirichlet forms was also recently exploited in the study of Liouville Brownian motions [GRV16a, GRV14, MRVZ16] which is closed related with the Liouville measure we are concerned in this paper.

**Remark 1.3.** In our notation, $\omega_g = e^{2\phi} \omega_0$ refers to the area form if $\phi$ is smooth or the “formal” area form if $\phi$ is rough. $M_\phi$ refers to the renormalized area form, i.e. GMC. Finally we will often denote a generic element in $\mathcal{X}$ by the notation $A$.

**Acknowledgements**

We would like to thank Rongchan Zhu, Rémi Rhodes and Vincent Vargas for useful discussions. JD gratefully acknowledges the support by the NSF grant DMS-1308476 and DMS-1512853. HS gratefully acknowledges the support by the NSF grant DMS-1712684 / DMS-1909525.
2 Integration by parts

A key step of implementing the machinery of Dirichlet forms is a proof of an integration-by-parts formula. At first glance the form of integration-by-parts formulas we will provide below (with respect to both a Gaussian free field measure $\mu$ and a Liouville CFT measure $\nu$) is similar to [AHK74, Theorem 5.3]; we quickly summarize the setup in the latter case in Lemma 2.1 below. But the main difference comparing with our case is that the functional therein is assumed to be “cylindrical” (or so-called “finite-dimensional base” therein), that is, of the form $G(\phi) = q(\int f_1 \phi \omega_0, \ldots, \int f_k \phi \omega_0)$. The Gaussian integration-by-parts formula for such cylindrical functionals (see [AHK74, Lemma 5.2 and (5.23)]) boils down to finite-dimensional Gaussian integration by parts essentially because $\int f_i \phi \omega_0$ are Gaussian. For our problem however, we need to consider a different class of functionals (see Definition 2.2 below), tailored to this specific situation. The proof of integration by parts is based on shift covariance of Liouville measure together with the Cameron-Martin formula.

Denote by $H = H^{\gamma/2}(\Lambda)$ the Sobolev Hilbert space. In the sequel we write $\Phi := H^{-\varepsilon}$ where $\varepsilon$ is a fixed, small positive real number. A general element $\phi \in \Phi$ can be uniquely decomposed as $\phi = m + \phi_0$, with $\phi_0$ zero-mean and $m \in \mathbb{R}$. We have the measure on $\Phi$

$$d\hat{\mu}(\phi) = dm \otimes d\mu(\phi_0)$$

where $dm$ is the Lebesgue measure on $\mathbb{R}$ and $\mu = \mu_\sigma$ is the Gaussian Free Field probability measure on zero-mean fields, for the covariance operator $\frac{\sigma^2}{2} (-\Delta)^{-1}$ (where $(-\Delta)^{-1}$ denotes the zero-mean Green kernel); $\sigma < 2\sqrt{\pi}$ is fixed. The $\sigma$-finite measure $dm \otimes d\mu(\phi_0)$ is (up to multiplicative constant) the natural interpretation of the path integral measure

$$e^{-\sigma^{-2} \int_\Lambda |\nabla \phi|^2 \omega_0} D\phi$$

(2.18)

Denote by $H = H^1(\Lambda)$ the Cameron-Martin space.

For any $A \in \mathcal{X}$, we denote by $L^2(A)$ the $L^2$ space with underlying measure $A$ on $\Lambda$. Recall that smooth functions are dense in $L^2(\Lambda)$, which is separable.

We start by recalling the classical results on gradients of test functionals and integration by parts for the Gaussian free field as in [AHK74] for the sake of comparison, without proof.

**Lemma 2.1.** (The “classical” case.) Let $G(\phi) = q(\int f_1 \phi \omega_0, \ldots, \int f_k \phi \omega_0)$ where $q : \mathbb{R}^k \to \mathbb{R}$ is a compactly supported $C^2$ function and the $f_i$’s are in $H^{-1}$. Then $G$ has bounded Fréchet derivative in Cameron-Martin directions and one has

$$D_h G(\phi) = \sum_{i=1}^k \partial_i q \left( \int f_1 \phi \omega_0, \ldots, \int f_k \phi \omega_0 \right) \cdot \int (f_i h) \omega_0$$

(2.19)

for any Cameron-Martin direction $h \in H$. The $L^2(\omega_0)$-gradient of $G$ is is characterized by $\langle DG(\phi), h \rangle_{L^2(\omega_0)} = D_h G(\phi)$ for all $h \in H^1$ a.s., and is given by

$$DG(\phi) = \sum_{i=1}^k \partial_i q \left( \int f_1 \phi \omega_0, \ldots, \int f_k \phi \omega_0 \right) f_i.$$ 

(2.20)
For such functionals $G$, we have the following Gaussian integration by parts

$$\frac{\sigma^2}{2} \int D_h G(\phi) \hat{\mu}(d\phi) = \int G(\phi) \langle \nabla h, \nabla \phi \rangle \hat{\mu}(d\phi)$$

(2.21)

where $d\hat{\mu}(\phi) = dm \otimes d\mu(\phi_0)$ as defined above.

As usual, $\langle \nabla h, \nabla \phi \rangle$ is defined everywhere if $h \in H^{2+\varepsilon}$ and a.e. (via Paley-Wiener) if $h \in H^1$.

### 2.1 Test functionals

We now define a class $\mathcal{C}$ of test functionals on $\Phi$ suitable for our purposes. To this end we recall the GMC mapping

$$\Phi \rightarrow X$$
$$\phi \mapsto M_\phi = :e^{2\phi_0}:$$

which is defined $\hat{\mu}$-almost everywhere, see Section 1.1.

**Definition 2.2.** Let $\tilde{\mathcal{C}}$ be the space of functionals on $\Phi$ of the form

$$G(\phi) = q(M_\phi(f_0), M_\phi(f_1), \ldots, M_\phi(f_k)) \quad \text{for } \phi \in \Phi$$

(2.22)

such that $q : \mathbb{R}^{k+1} \rightarrow \mathbb{R}$ is a $C^2$ function and $f_i$ are smooth functions with $f_0 \equiv 1$.

Let $\mathcal{C} \subset \tilde{\mathcal{C}}$ be the space of functionals $G \in \tilde{\mathcal{C}}$ on $\Phi$ such that there exists a compactly supported $q : \mathbb{R}^{k+1} \rightarrow \mathbb{R}$ i.e.

$$\text{Supp}(q) \subset (\varepsilon, \varepsilon^{-1}) \times Q \quad \text{(for some } \varepsilon \in (0, 1) \text{ and } Q \subset \mathbb{R}^k \text{ compact})$$

(2.23)

so that $G$ is of the form (2.22).

We now compute Fréchet derivatives and gradient of functionals in $\tilde{\mathcal{C}}$. Denote by $C^0(\Lambda)$ the space of continuous functions on $\Lambda$.

**Lemma 2.3.** Let $G \in \tilde{\mathcal{C}}$ be of the form (2.22). Then $G$ has the Fréchet derivative

$$D_h G(\phi) = 2 \sum_{i=0}^{k} \partial_i q(M_\phi(f_0), \ldots, M_\phi(f_k)) \cdot M_\phi(f_i h)$$

(2.24)

for any $h \in C^0(\Lambda) \cap H$. In particular $D_h M_\phi(f) = 2M_\phi(fh)$.

The $L^2(M_\phi)$-gradient of $G$ is characterized by

$$\langle DG(\phi), h \rangle_{L^2(M_\phi)} = D_h G(\phi)$$

(2.25)

$\hat{\mu}$-a.e. for any $h \in C^0(\Lambda) \cap H$, and is given by

$$DG(\phi) = 2 \sum_{i=0}^{k} \partial_i q(M_\phi(f_0), \ldots, M_\phi(f_k)) \cdot f_i.$$  

(2.26)

Finally, if we further have $G \in \mathcal{C}$, then the Fréchet derivative $D_h G$ is bounded for all $\phi \in \Phi$.  

11
Proof. We first remark that for a fixed \( \phi \), \( M_\phi(f_i,h) < \infty \) so that the right-hand side of (2.24) is well-defined. This is because \( f_i \) and \( h \) are continuous on \( \Lambda \) thus bounded, and \( M_\phi \) is finite.

By the shift property (1.13),
\[
M_{\phi+th}(f) = (e^{2t-h}M_\phi)(f) = \int_\Lambda f(x)e^{2t-h(x)}M_\phi(dx) \quad \text{a.e.}
\]
for any \( h \in H \). One then has
\[
G(\phi + th) - G(\phi) = q \left( (e^{2t-h}M_\phi)(f_1), \ldots, (e^{2t-h}M_\phi)(f_k) \right) - q(M_\phi(f_1), \ldots, M_\phi(f_k))
\]
\[
= \sum_{i=1}^k q \left( M_\phi(f_1), \ldots, M_\phi(f_{i-1}), (e^{2t-h}M_\phi)(f_i), \ldots, (e^{2t-h}M_\phi)(f_k) \right)
\]
\[
- q(M_\phi(f_1), \ldots, M_\phi(f_i), (e^{2t-h}M_\phi)(f_{i+1}), \ldots, (e^{2t-h}M_\phi)(f_k))
\]
\[
= t \cdot \sum_{i=1}^k \partial_i q \left( M_\phi(f_1), \ldots, M_\phi(f_{i-1}), (e^{2t-h}M_\phi)(f_i), \ldots, (e^{2t-h}M_\phi)(f_k) \right)
\]
\[
\quad \cdot \left. \frac{d}{dt} \right|_{t=t^*} \int_\Lambda f_i(x)e^{2t-h(x)}M_\phi(dx)
\]
for some \( t^* \in [0,t] \). By the aforementioned boundedness of \( h \) we can bound \( e^{2t-h(x)} \) by a constant, and thus by dominated convergence theorem one has that \( \frac{d}{dt} \big|_{t=0} G(\phi + th) \) is equal to the right-hand side of (2.24).

Once we have the Fréchet derivatives \( D_hG \), the gradient \( DG \) then exists and is unique by Riesz representation theorem, since the space \( C^0(\Lambda) \cap H \) is dense in \( L^2(M_\phi) \). Indeed, the GMC measure \( M_\phi \) is a Radon measure that is inner and outer regular, so for any Borel set \( A \subset \Lambda \) there exist an open set \( U \) and a compact set \( K \) such that \( K \subset A \subset U \) and \( M_\phi(U \setminus K) \) is arbitrarily small, then by Urysohn’s lemma one obtains a continuous function which is supported on \( U \) and equal to 1 on \( K \), thus approximates the characteristic function of \( A \) in the \( L^2(M_\phi) \) topology. The simple functions, namely linear combinations of the characteristic functions are then dense in \( L^2(M_\phi) \) by construction of integrals with respect to the GMC \( M_\phi \).

Regarding the identity (2.26), with \( DG \) in (2.26) one can immediately check that
\[
M_\phi(h \cdot DG) = D_hG ,
\]
namely (2.25) holds.

If \( G \in C \), \( D_hG \) is bounded. In fact, since \( f_i, h \) are continuous, \( |M_\phi(f_i,h)| \leq CM_\phi(1) \); and by the fact that \( \partial_i q = 0 \) when \( M_\phi(1) \notin (e, e^{-1}) \), one obtains the boundedness of
\[
\partial_i q(M_\phi(1), M_\phi(f_1), \ldots, M_\phi(f_k))M_\phi(1) .
\]

\( \square \)

Obviously, \( D_hG \) and \( DG \) do not depend on the representation (2.22), namely if \( G(\phi) \) is equal to \( \tilde{q}(M_\phi(\tilde{f}_0), \ldots, M_\phi(\tilde{f}_k)) \) for some other functions \( \tilde{q} \) and \( \{\tilde{f}_1, \ldots, \tilde{f}_k\} \) and
\[ \ell \geq 0, \text{ then the right-hand side of (2.24) or (2.26) with } q \text{ and } \{ f_1, \cdots, f_\ell \} \text{ replaced by } \tilde{q} \text{ and } \{ \tilde{f}_1, \cdots, \tilde{f}_\ell \} \text{ remains identical. Indeed we showed that } D_h G = \lim_{t \searrow 0} \frac{G(\phi + th) - G(\phi)}{t} \text{ a.e., and } DG \text{ is characterized by the } D_h G \text{’s.} \]

We also note that the Leibniz rule holds:

\[ D_h (GH) = (D_h G)H + G(D_h H) \quad \forall \, G, H \in \mathcal{C}. \quad (2.27) \]

Indeed, for \( G(\phi) = q(M_\phi(f_1), \cdots, M_\phi(f_\ell)) \) and \( H(\phi) = p(M_\phi(g_1), \cdots, M_\phi(g_\ell)) \), we have \((GH)(\phi) = r(M_\phi(f_1), \cdots, M_\phi(f_\ell), M_\phi(g_1), \cdots, M_\phi(g_\ell))\) where \( r(x_1, \cdots, y_\ell) \) equals \( q(x_1, \cdots, x_\ell)p(y_1, \cdots, y_\ell) \). So by the formula (2.24) we have that \( D_h(GH)(\phi) = 2 \sum_{j=1}^{\ell} \partial_{y_j} r \cdot M_\phi(g_j h) \) which is equal to the right-hand side of (2.27).

### 2.2 Proof of integration by parts

**Lemma 2.4.** Let \( \mu \) be the law of a mean zero GFF \( \phi_0 \) on \( \Lambda \), with covariance operator \( \sigma^2 (\Delta)^{-1} \), \( \phi = \phi_0 + m \), and \( d\mu(\phi) = dm \otimes d\mu(\phi_0) \). Then we have the following Gaussian integration by parts

\[
\frac{\sigma^2}{2} \int \frac{dT_s^{th} \mu}{d\mu} = \int G(\phi) \langle \nabla h, \nabla \phi \rangle \mu(\phi) \quad \forall G \in \mathcal{C} \quad (2.28)
\]

and \( D_h \) is the Fréchet derivative in the Cameron-Martin direction \( h \in C^0(\Lambda) \cap H \).

**Proof.** By boundedness of \( D_h G \) from Lemma 2.3 and boundedness of \( G \) by definition, both sides of (2.28) are well-defined. Recall that \( H = H^1 \) is the Cameron-Martin Hilbert space, endowed with \( \langle \cdot, \cdot \rangle_H \). For \( h \in H \) with mean zero and \( t \in \mathbb{R} \), one has the Cameron-Martin formula

\[
\frac{dT_s^{th} \mu}{d\mu} = \exp \left( t \langle \phi_0, h \rangle_H - \frac{t^2}{2} \| h \|_H^2 \right)
\]

where \( T_s^{th} \mu \) denotes the push-forward measure of \( \mu \) in the direction \( th \). Let \( G \) be as assumed above. One then has

\[
\frac{\sigma^2}{2} \int_{\mathbb{R}} \frac{d}{dt} \int G(m + \phi_0 + th) \mu(\phi_0) dm \\
= \frac{\sigma^2}{2} \int_{\mathbb{R}} \int_{\mathbb{R}} G(m + \phi_0) \exp \left( t \langle \phi_0, h \rangle_H - \frac{t^2}{2} \| h \|_H^2 \right) \mu(\phi_0) dm.
\quad (2.29)
\]

Since \( \langle \phi_0, h \rangle_H = \int \nabla h \cdot \nabla \phi_0 = \langle \phi, h \rangle_H \), it remains to differentiate the above identity in \( t \) at \( t = 0 \) using dominated convergence theorem.

Again since \( G \) has bounded Fréchet derivative by Lemma 2.3 we have that differentiating the l.h.s. of (2.29) w.r.t. \( t \) at \( t = 0 \) using dominated convergence yields l.h.s. of (2.28).

For the r.h.s. of (2.29), for sufficiently small \( t > 0 \) one has

\[
\left| \frac{d}{dt} \exp \left( t \langle \phi_0, h \rangle_H - \frac{t^2}{2} \| h \|_H^2 \right) \right| = \left| \langle \phi_0, h \rangle_H - t\| h \|_H^2 \exp \left( t \langle \phi_0, h \rangle_H - \frac{t^2}{2} \| h \|_H^2 \right) \right|
\]

13
\[ \leq C \exp \left( a \left| \langle \phi_0, h \rangle_H \right| \right) \]

for some constants \( a, C > 0 \).

By (2.32) in Lemma 2.5 and boundedness of \( G \), one has that
\[ G(m + \phi_0) \cdot \exp \left( a \left| \langle \phi_0, h \rangle_H \right| \right) \]
is \( \hat{\mu} \)-integrable over fields such that \( M_\phi(\Lambda) \in [\varepsilon, \varepsilon^{-1}] \), where \( \varepsilon \) is the constant arising from the specification of the support in the first coordinate of \( G \), see (2.23). For \( M_\phi(\Lambda) \notin [\varepsilon, \varepsilon^{-1}] \), \( G(m + \phi_0) \) simply vanishes by assumption. Therefore dominated convergence applies and the derivative of the r.h.s. of (2.29) w.r.t. \( t \) at \( t = 0 \) is
\[ \int \int G(\phi_0 + m) \langle \nabla h, \nabla \phi_0 \rangle \mu(d\phi_0) dm. \]

This is the r.h.s. of (2.28). We thus showed that (2.28) holds if \( h \) has mean zero. If \( h \) is constant, both sides of (2.28) are zero (by translation invariance of \( dm \)); this concludes by linearity.

Let \( \nu \) be the Liouville CFT measure on \( H^{-\varepsilon} \) given by (recall the conventions about the parameters (1.14))
\[ d\nu(\phi) = \exp \left( - \frac{\lambda}{\sigma^2} M_\phi(\Lambda) \right) dm \otimes d\mu(\phi_0) \tag{2.30} \]
where \( \phi = m + \phi_0 \). The Liouville CFT measure \( \nu \) has been rigorously constructed by [DRV16, GRV16b] with suitable insertions of vertex operators. Without insertions on the torus \( \nu \) is not normalizable because the integral of \( \nu \) would diverge as \( \phi \to -\infty \) (so that \( M_\phi(\Lambda) \to 0 \)). Here we do not consider insertions but instead we verify that \( \nu \) is \( \sigma \)-finite, see Lemma 2.5.

We start with a basic integrability result. Recall that \( \nu \) depends on the parameters \( \sigma < \sigma_{L,1} \) and \( \lambda > 0 \).

**Lemma 2.5.** \( \nu \) is \( \sigma \)-finite; more precisely, for any \( \varepsilon \in (0,1) \),
\[ \nu(\{ \phi : \varepsilon < M_\phi(\Lambda) < \varepsilon^{-1} \}) < \infty. \]

Moreover, for \( f \in H \),
\[ \phi \mapsto \langle f, \Delta \phi \rangle_1 \chi_{[\varepsilon,\varepsilon^{-1}]}(M_\phi(\Lambda)) \tag{2.31} \]
is in \( L^p(\hat{\mu}) \) and \( L^p(\nu) \) for all \( p \in [1, \infty) \), and for \( a > 0 \)
\[ \phi \mapsto \exp \left( a \left| \langle \phi_0, f \rangle_H \right| \right) \chi_{[\varepsilon,\varepsilon^{-1}]}(M_\phi(\Lambda)) \tag{2.32} \]
is integrable with respect to \( \hat{\mu} \) and \( \nu \).
Proof. Note that the Gaussian measure \( \mu \) on zero-mean fields \( \{ \phi_0 \} \) on the torus is a probability measure. By the shift property of the GMC, we have

\[
\int_{-\infty}^{\infty} \int_{\Phi} 1_{\varepsilon < M_{\phi_0}(\Lambda) < \varepsilon^{-1}} d\mu(\phi_0) \, d\mu = \int_{-\infty}^{\infty} \int_{\Phi} 1_{\varepsilon^{-2} < M_{\phi_0}(\Lambda) < \varepsilon^{-2}} d\mu(\phi_0) \, d\mu
\]

\[
\leq \sum_{k = -\infty}^{\infty} \int_{k \log \varepsilon}^{(k+1) \log \varepsilon} \mu\left( \varepsilon^{2k+3} < M_{\phi_0}(\Lambda) < \varepsilon^{2k-1} \right) \, d\mu
\]

\[
\leq C' \sum_{k = -\infty}^{\infty} \mu\left( \varepsilon^{2k+3} < M_{\phi_0}(\Lambda) < \varepsilon^{2k-1} \right) \leq C < \infty
\]

where the constants \( C', C \) depend on \( \varepsilon \). Here note that for the intervals \( (\varepsilon^{2k+3}, \varepsilon^{2k-1}) \subset (0, \infty) \) in the second line only two adjacent intervals overlap, and in the last step the intervals \( (\varepsilon^{2k+3}, \varepsilon^{2k-1}) \subset (0, \infty) \) are non-overlapping so that we can make use of the fact that \( \mu \) is a finite measure. This shows that

\[
\hat{\mu}(\{ \phi : \varepsilon < M_{\phi_0}(\Lambda) < \varepsilon^{-1} \}) \leq C.
\]

Together with \( \exp\left( -\frac{A}{\sigma^2} M_{\phi}(\Lambda) \right) \leq 1 \) this gives the first claim.

From Proposition 3.5 and 3.6 in [RV10], we have the following positive and negative moment estimates for the total mass of a GMC:

\[
\int_{\Phi} (M_{\phi_0}(\Lambda))^p \, d\mu(\phi_0) < \infty
\]

for all \( p < 0 \) and for some \( p = p(\sigma) > 1 \). In particular, by Markov’s inequality, for \( x \) large,

\[
\mu(\{ M_{\phi_0}(\Lambda) \geq x \}) = O(x^{-1}), \quad \mu(\{ M_{\phi_0}(\Lambda) \leq x^{-1} \}) = O(x^{-1}).
\]

For \( f \in H \), \( \langle f, \Delta \phi \rangle = \langle f, \Delta \phi_0 \rangle \) is Gaussian and hence has moments of all orders (under \( \mu \)). Then

\[
\int_{-\infty}^{\infty} \int_{\Phi} |\langle f, \Delta \phi \rangle|^p 1_{[\varepsilon^{-1}, \varepsilon]}(M_{\phi}(\Lambda)) \, d\mu(\phi_0) \, dm \leq \sum_{k = -\infty}^{\infty} \int_{k \log \varepsilon}^{(k+1) \log \varepsilon} \int_{\Phi} |\langle f, \Delta \phi \rangle|^p 1_{[\varepsilon^{2k}, \varepsilon^{2k-1}]}(M_{\phi_0}(\Lambda)) \, d\mu(\phi_0) \, dm
\]

\[
\leq C \sum_{k = -\infty}^{\infty} \left( |\langle f, \Delta \phi_0 \rangle|^p \| L^2(\mu) \| \| f \|^2 L^2(\mu) \| \mu\left( \varepsilon^{3+2k} < M_{\phi_0}(\Lambda) < \varepsilon^{2k-1} \right) \right)^{1/2}
\]

by Cauchy-Schwarz and the previous estimate.

The last statement (2.32) is proved in the same way given that \( \langle \phi_0, f \rangle \) is centered Gaussian random variable with variance \( \| f \|^2_H \), so that

\[
\| e^{a \langle \phi_0, f \rangle} \| L^2(\mu) \leq \| e^{a \langle \phi_0, f \rangle} \| L^2(\mu) + \| e^{-a \langle \phi_0, f \rangle} \| L^2(\mu) = 2e^{a^2} \| f \|^2_H < \infty.
\]

The estimate (2.33) with \( |\langle f, \Delta \phi_0 \rangle|^p \| L^2(\mu) \| \) replaced by \( e^{a \langle \phi_0, f \rangle} \| L^2(\mu) \| \) then shows that \( e^{a \langle \phi_0, f \rangle} \) is integrable for \( a > 0 \) with respect to the Gaussian measure \( \hat{\mu} \) and thus also \( \nu \).
Theorem 2.6. (Integration by parts for Liouville CFT $\nu$) For any $G \in \mathcal{C}$ and $h \in C^0(\Lambda) \cap H$

$$\int G(\phi)(\nabla \phi, \nabla h) d\nu(\phi) = \int \left( \frac{\sigma^2}{2} D_h G(\phi) - \lambda G(\phi) M_\phi(h) \right) d\nu(\phi). \quad (2.34)$$

Proof. We first remark that all the three terms in (2.34) are $\nu$-integrable. Indeed, the left-hand side of (2.34) is finite, since by the assumption (2.23) one can bound $G$ by a constant times $1_{[\epsilon, \epsilon^{-1}]}(M_\phi(1))$, and then we apply the integrability of (2.31) in Lemma 2.5. Regarding the right-hand side of (2.34), by the formula (2.24) and the assumption (2.23) we can bound $D_h G$ by $C_\epsilon^{-1} 1_{[\epsilon, \epsilon^{-1}]}(M_\phi(1))$ for some constant $C > 0$, which is again integrable by Lemma 2.5. The same bound holds for $\lambda G(\phi) M_\phi(h)$ and thus is integrable too.

To prove (2.34), note that the left-hand side of (2.34) equals

$$\int G(\phi)(\nabla \phi, \nabla h) e^{-\frac{\lambda}{\sigma^2} M_\phi(1)} d\mu(\phi) = \frac{\sigma^2}{2} \int D_h \left( G(\phi) e^{-\frac{\lambda}{\sigma^2} M_\phi(1)} \right) d\mu(\phi) \quad (2.35)$$

where we applied Lemma 2.4 to the functional $G(\phi) e^{-\frac{\lambda}{\sigma^2} M_\phi(1)} \in \mathcal{C}$.

By Lemma 2.3

$$D_h e^{-\frac{\lambda}{\sigma^2} M_\phi(1)} = -\frac{2\lambda}{\sigma^2} M_\phi(h) e^{-\frac{\lambda}{\sigma^2} M_\phi(1)}. \quad (2.36)$$

Invoking this in (2.35) and applying (2.27) we obtain the right-hand side of (2.34). \qed

3 Solution via Dirichlet forms

The construction of the weak solution via Dirichlet forms consists of three steps. 1. Showing closability of the Dirichlet form; 2. Proving existence of Hunt process associated to the Dirichlet form; 3. Proving the process solves the equation in certain sense.

Recall from Section 1.1 that there is an a.e. correspondence $\phi \leftrightarrow M_\phi$. We denote by $m$ the image measure of the Liouville CFT measure $\nu$ by the measurable map $M$

$$\Phi \rightarrow \mathcal{X}$$

$$\phi \mapsto M(\phi) = M_\phi \quad (3.37)$$

Then $m = M_* \nu$ is a Radon measure on $\mathcal{X}$, see Lemma 2.5. We denote by $L^2(\mathcal{X}, m)$ the Hilbert space of square integrable $m$-measurable functions on $\mathcal{X}$. We denote by $M^{-1}$ an a.e. inverse measurable map to $M$. The spaces $L^2(\mathcal{X}, m)$ and $L^2(\Phi, \nu)$ are isometric under the pull back map $M^* = (M^{-1})_*$.

Recall that $\mathcal{X}$ is locally compact while $\Phi$ is merely Polish.

We will first introduce a form on $\Phi$, and then, induce a form on $\mathcal{X}$. To this end we define the following class of test functions $C_\mathcal{X}$ on $\mathcal{X}$: $C_\mathcal{X}$ consists of test functionals $F : \mathcal{X} \rightarrow \mathbb{R}$ such that $F(A) = q(\int f_0 dA, \ldots, \int f_k dA)$ for some smooth functions $f_0, \ldots, f_k \in C^\infty(\Lambda)$ and some function $q$ as in Definition 2.2 and satisfying (2.23).

Let $C_0(\mathcal{X})$ be the space of compactly supported continuous functions on $\mathcal{X}$ with uniform norm.
Lemma 3.1. $\mathcal{C}_X$ is dense in $C_0(\mathcal{X})$, and is dense in $L^2(\mathcal{X}, \mathbf{m})$. The space $\mathcal{C}$ is dense in $L^2(\Phi, \nu)$.

Proof. To prove that $\mathcal{C}_X$ is dense in $C_0(\mathcal{X})$, by the Stone-Weierstrass theorem for locally compact spaces, it suffices to prove that $\mathcal{C}_X$ is an algebra of functions which separates points in $\mathcal{X}$ and vanishes nowhere. $\mathcal{C}_X$ is clearly an algebra and it vanishes nowhere: indeed, for any $M \in \mathcal{X}$, recalling that $\mathcal{X} \simeq M_1(\Lambda) \times (0, \infty)$ one has $M(1) = M(\Lambda) \in (0, \infty)$ so $F(M) := q(M(1)) \in \mathcal{C}_X$ is not equal to 0 for any function $q$ that does not vanish at $M(1)$. It is also clear that $\mathcal{C}_X$ separates points in $\mathcal{X}$: indeed, for $M_1 \neq M_2 \in \mathcal{X}$, there must exist $f$ smooth such that $M_1(f) \neq M_2(f)$, thus $F(M) := q(M(f)) \in \mathcal{C}_X$ with this function $f$ separates $M_1$ and $M_2$ for any choice of function $q$ which takes different values at $M_1(f)$ and $M_2(f)$.

Since $\mathbf{m}$ is a Radon measure on $\mathcal{X}$, by the same argument as in Proof of Lemma 2.3 namely using inner and outer regularities of $\mathbf{m}$ with Urysohn’s lemma, one has that $C_0(\mathcal{X})$ is dense in $L^2(\mathcal{X}, \mathbf{m})$.

The fact that $\mathcal{C}$ is dense in $L^2(\Phi, \nu)$ follows immediately due to the aforementioned isometry.

Clearly $\mathcal{C}_X \subset L^p(\mathbf{m})$ for all $p < \infty$ by Lemma 2.5. Moreover, if $F \in \mathcal{C}_X$, then $\tilde{F} = F \circ \mathbf{M}$ is in $\mathcal{C}$.

3.1 Closability of the Dirichlet form

Definition 3.2. For $F(\phi) = q(M_\phi(f_1), \ldots, M_\phi(f_k)) \in \mathcal{C} =: \mathcal{D}(\mathcal{L})$, we define

$$L F(\phi) := 2 \sum_{i=1}^k \partial_i q \cdot \left( \langle f_i, \Delta \phi \rangle - \lambda M_\phi(f_i) \right) + 2\sigma^2 \sum_{i,j=1}^k \partial^2_{ij} q \cdot M_\phi(f_i f_j)$$

(3.38)

where $\partial_i q$ and $\partial^2_{ij} q$ are evaluated at $(M_\phi(f_1), \ldots, M_\phi(f_k))$.

Here $L F$ is defined $\mu$- (equivalently, $\nu$-) almost everywhere. Recall that $\phi \mapsto \langle f, \Delta \phi \rangle = \langle \Delta f, \phi \rangle$ is continuous on the abstract Wiener space if $f$ is regular enough (e.g. if $f$ is $C^3$).

Definition 3.3. For $F, G \in \mathcal{C}$ we define a bilinear form

$$\mathcal{E}(F,G) := \int F(\phi)(-LG(\phi))d\nu(\phi) .$$

(3.39)

Lemma 3.4. We have

$$\mathcal{E}(F,G) = \frac{1}{2} \int \langle DF(\phi), DG(\phi) \rangle_{L^2(M_\phi)}d\nu(\phi) .$$

(3.40)

In particular, $\mathcal{E}$ is symmetric and positive semidefinite on $\mathcal{D}(\mathcal{L})^2$.

Remark 3.5. Taking $F \equiv 1$ in (3.39) we have $DF = 0$, and by Lemma 3.4 one has $\int LF(\phi)d\nu(\phi) = 0$, which reflects symmetry of the dynamic we will eventually construct with respect to the Liouville CFT.
Remark 3.6. Lemma 2.3 and Lemma 3.4 together implies that $E(F,G)$ defined in (3.39) does not depend on the representation of $F,G$ in the form (2.22). Moreover, since $\mathcal{C}$ is dense in $L^2(\nu)$ by Lemma 3.4, it follows that $\mathcal{L} F = \mathcal{L} \tilde{F}$ $\nu$-a.e. if $F = \tilde{F}$ $\nu$-a.e., i.e. $\mathcal{L}F$ uniquely depends on $F$ and not on any particular choice of $q,f_1,\ldots,f_k$. Also, note that $L$ is linear on the domain $\mathcal{D}(\mathcal{L})$. Indeed, for

$$F(\phi) = p(M_\phi(f_1),\ldots,M_\phi(f_k)) \quad \text{and} \quad G(\phi) = q(M_\phi(f_{k+1}),\ldots,M_\phi(f_n)),$$

a linear combination has the form $(a F + b G)(\phi) = r(M_\phi(f_1),\ldots,M_\phi(f_n))$ where $\partial^2_{ij} r = 0$ unless $\{i,j\} \subset \{1,\ldots,k\}$ or $\{i,j\} \subset \{k+1,\ldots,n\}$; this together with the independence of $\mathcal{L}F$ on the representation of $F$ implies linearity of $\mathcal{L}$.

Remark 3.7. Note that the $E$ in (3.40) has a novel form, in the sense that the $L^2$ product in (3.40), as well as the notion of gradient (2.25), depend on the GMC measure $M_\phi$. To compare with the earlier work, for instance [AR91], one usually has a fixed Hilbert space $\langle H, \langle , \rangle_H \rangle$ and consider forms such as $\frac{1}{2} \int (A(\phi) DF(\phi), DG(\phi))_H \nu d\nu(\phi)$ where $A(\phi)$ is some bounded linear operator on $H$. In our case since $M_\phi$ does not have a density with respect to a fixed measure (such as Lebesgue measure), our form $E$ does not fit into the scope of [AR91]. Our “tangent spaces” of $\Phi$ do depend on $\phi \in \Phi$ in a nontrivial way (see Eq. (1.6) for this heuristic). It also worth noting at this point that a simpler form $\frac{1}{2} \int (DF(\phi), DG(\phi))_H \nu d\nu(\phi)$ with $H = L^2(\Lambda,d^2x)$ which is called a “classical” Dirichlet form in [AR91] corresponds to the equation studied by [Gar18], which is formally given by (via a simple change of parameters)

$$\partial_t \phi = \frac{1}{4\pi} \phi - e^{\gamma \phi} + \xi$$

where $\xi$ is the space-time white noise with respect to the Euclidean metric. The framework of [AR91] constructs a diffusion w.r.t. this “classical” Dirichlet form. ([AR91, Section 7.11.a]) focuses on the $P(\Phi)_2$ case but it is remarked that the Høegh-Krohn case on $\mathbb{R}^2$ with a space cutoff can be treated similarly.) The integration-by-parts formula required in their setting can be found in [AIK74], as we recorded above in the beginning of Section 2, which has the same form as our integration by parts formula but is w.r.t cylindrical test functionals.

Proof of Lemma 3.4. Letting $F = p(M_\phi(f_1),\ldots,M_\phi(f_{m}))$ and $G = q(M_\phi(g_1),\ldots,M_\phi(g_n))$, by definition (3.38) of the generator $\mathcal{L}$ one has that the right-hand side of (3.39) is equal to

$$-2 \sum_{i=1}^{n} \int p \partial_i q \cdot (g_i, \Delta \phi) \, d\nu(\phi) + 2\lambda \int p \sum_{i=1}^{n} \partial_i q \cdot M_\phi(g_i) \, d\nu(\phi)$$

$$-2\sigma^2 \sum_{i,j=1}^{n} \int p \sum_{i=1}^{n} \partial_i \partial_j q \cdot M_\phi(g_i,g_j) \, d\nu(\phi)$$

\[\text{Eq. (3.41)}\]

[Gar18] proved that when $\gamma \in [0,2\sqrt{2} - \sqrt{6}]$ one can define a local solution for the suitably renormalized equation, and obtained convergence of the mollified solutions to the limiting solution; when $\gamma \in [2\sqrt{2} - \sqrt{6}, 2\sqrt{2} - 2)$, there is still a notion of local solution but with no convergence result.
where we omitted the arguments of $p,q$. We remark that every term here is indeed integrable, as shown in the proof of Lemma 2.6. For each fixed $i \in \{1, \cdots, n\}$, we apply integration by parts (Theorem 2.6) to the functional $2p \partial_i q$ in the first term of (3.41) with Cameron-Martin direction $g_i$ (which is smooth) and get

$$-2 \sum_{i=1}^{n} \int p \partial_i q \cdot \langle g_i, \Delta \phi \rangle \, d\nu(\phi) = 2 \sum_{i=1}^{n} \int p \partial_i q \cdot \langle \nabla g_i, \nabla \phi \rangle \, d\nu(\phi)$$

$$= \sum_{i=1}^{n} \int \left( \sigma^2 D_{g_i}(p \partial_i q) - 2\lambda p \partial_i q M_{\phi}(g_i) \right) \, d\nu(\phi)$$

$$= \sum_{i=1}^{n} \int \left( 2\sigma^2 p \sum_{j=1}^{n} \partial_i \partial_j q \cdot M_{\phi}(g_i g_j) + 2\sigma^2 \sum_{j=1}^{m} \partial_j p \partial_i q \cdot M_{\phi}(g_i f_j) - 2\lambda p \partial_i q M_{\phi}(g_i) \right) \, d\nu(\phi)$$

where in the last step we computed $D_{g_i}$ using (2.24) of Lemma 2.3. Note that the first and the third terms in the last line here cancel the second and the third terms in (3.41). Therefore the above calculation shows that the right-hand side of (3.39) is equal to

$$\sum_{i=1}^{n} \int \left( 2\sigma^2 \sum_{j=1}^{m} \partial_j p \partial_i q \cdot M_{\phi}(g_i f_j) \right) \, d\nu(\phi). \tag{3.42}$$

This expression, using (2.26), is equal to the right-hand side of (3.40). \hfill \Box

We will now induce a bilinear form on $\mathcal{X}$. Define a form on $L^2(\mathcal{X}, \mu)$ by

$$\mathcal{E}_{\mathcal{X}}(F,G) := \mathcal{E}(F \circ M, G \circ M) \tag{3.43}$$

for $F,G \in \mathcal{C}_{\mathcal{X}}$. It is clearly symmetric and positive semi-definite by Lemma 3.4. $C_{\mathcal{X}}$ is dense in $L^2(\mathcal{X}, \mu)$ by Lemma 3.1.

**Lemma 3.8.** The form $\mathcal{E}_{\mathcal{X}}$ is closable for every $\sigma < \sigma_{L^1} = 2\sqrt{\pi}$.

**Proof.** By [FOT11, Eq. (1.1.3)], a sufficient condition for the symmetric form $\mathcal{E}_{\mathcal{X}}$ to be closable is: for any sequence $F_n \in \mathcal{C}_{\mathcal{X}}$ with $\|F_n\|_{L^2(\mathcal{X}, \mu)} \to 0$ as $n \to \infty$ one always has

$$\lim_{n \to \infty} \mathcal{E}_{\mathcal{X}}(F_n, G) \to 0, \quad \forall G \in \mathcal{C}_{\mathcal{X}}.$$

Indeed, with these $F_n, G \in \mathcal{C}_{\mathcal{X}}$, denoting $\tilde{F}_n = F \circ M$, $\tilde{G} = G \circ M$, with $\tilde{F}_n, \tilde{G} \in \mathcal{C}$, we have:

$$|\mathcal{E}_{\mathcal{X}}(F_n, G)| = \left| \int \tilde{F}_n(-\mathcal{L}\tilde{G}) \, d\nu \right| \leq \|F_n\|_{L^2(\mathcal{X}, \mu)} \|\mathcal{L}\tilde{G}\|_{L^2(\nu)}.$$ 

Recall that $\mathcal{C}_{\mathcal{X}} \subset L^p(\mu)$ for all $p < \infty$. By the expression of $\mathcal{L}\tilde{G}$ (3.38) and Lemma 2.5 it follows that $\mathcal{L}\tilde{G}$ is in $L^p(\nu)$ for all $p < \infty$, which concludes. \hfill \Box

We also denote by $\mathcal{E}_{\mathcal{X}}$ the smallest closed extension (see [FOT11 Section 1.1]).

**Lemma 3.9.** $\mathcal{E}_{\mathcal{X}}$ is a Dirichlet form which is regular on $L^2(\mathcal{X}, \mu)$.
Proof. Recall from [FOT11] that for $\mathcal{E}_X$ to be regular we need to prove that $\mathcal{E}_X$ possesses a core. For this we need that $C_X$ is dense in $C_0(X)$ - the space of compactly supported continuous functions on $X$ with uniform norm. This is the content of Lemma 3.1.

Clearly, it is also a standard core, namely $C_X$ is a dense linear subspace of $C_0(X)$; and for any $\varepsilon > 0$, a cutoff function $\phi_\varepsilon$ as above which is further assumed to be differentiable, one has that $\phi_\varepsilon(F) \in C_X$ since $\phi_\varepsilon \circ q$ satisfies the requirements in Definition 2.2.

We also need to check that $\mathcal{E}_X$ is Markovian. Indeed, taking a cutoff function $\phi_\varepsilon$ as above which is further assumed to be differentiable, one has that for each $F(A)$ as above

$$D(\phi_\varepsilon \circ F)(A) = 2 \sum_{i=1}^{k} (\phi_\varepsilon' \circ q)(A(f_1), \ldots, A(f_k)) \cdot \partial_i q(A(f_1), \ldots, A(f_k)) \cdot f_i$$

so that (using the calculation (3.42) and the equivalence (3.43))

$$\mathcal{E}_X(\phi_\varepsilon \circ F, \phi_\varepsilon \circ F) = \frac{1}{2} \int (\phi_\varepsilon' \circ q)^2(A(f_1), \ldots, A(f_k)) \langle DF(\phi), DG(\phi) \rangle_{L^2(M_\phi)} d\nu(\phi).$$

Since $\phi_\varepsilon' \in (0, 1]$ and $\langle DF(\phi), DG(\phi) \rangle_{L^2(M_\phi)} \geq 0$, one has $\mathcal{E}_X(\phi_\varepsilon \circ F, \phi_\varepsilon \circ F) \leq \mathcal{E}_X(F, F)$, namely $\mathcal{E}_X$ is Markovian.

3.2 Existence of diffusion process

Proposition 3.10. There exists a unique $\textbf{m}$-symmetric diffusion $A = (\Omega, \mathcal{F}, (A_t), (P_z))$ on $X$ associated to $\mathcal{E}_X$.

Here the uniqueness of $\textbf{m}$-symmetric Hunt process is up to equivalence in the sense of [FOT11, Section 4.2]. Recall from [FOT11, Section 4.5] that a Hunt process is called a diffusion if

$$P_z(t \mapsto A_t \text{ is defined and continuous for all } t \in (0, \zeta)) = 1$$

(3.44)

for every $z \in X$, where $\zeta$ is the lifetime of $A$ in the sense of [FOT11, Appendix A.2]; also recall that by [FOT11, Theorem 4.5.1], there exists an $\textbf{m}$-symmetric diffusion on $X$ which is equivalent with $A$ if and only if $A$ is of continuous paths for quasi-every starting point, i.e. there exists a properly exceptional set $N$ such that (3.44) holds for every $z \in X \setminus N$. Here $N$ being properly exceptional set means that $N$ is nearly Borel measurable (see [FOT11, Appendix A.2]), $\textbf{m}(N) = 0$ and $X \setminus N$ is $A$-invariant, see [FOT11, Section 4.1].

Proof. Since $\mathcal{E}_X$ is regular, by [FOT11, Theorem 7.2.1], there exists an $\textbf{m}$-symmetric Hunt process associated to $\mathcal{E}_X$. By [FOT11, Theorem 7.2.2 or Theorem 4.5.1], for this Hunt process to be a diffusion we need to show locality of $\mathcal{E}_X$. 

20
To prove locality, let \( F, G \in \mathcal{C}_X \) with disjoint (compact) support. We want to show: \( \mathcal{E}_X(F, G) = 0 \). Take \((e_k)\) a sequence of smooth functions dense in \( C_0(\Lambda) \) and let

\[
d_n(A, A') = \sum_{k=0}^{n} 2^{-k} (|A(e_k) - A'(e_k)| \land 1)
\]
and \( d = \lim d_n; \) then \( d \) metrizes \( X \). Then

\[
\inf \{ d(A, A') : A \in \text{Supp}(F), A' \in \text{Supp}(G) \} > 0
\]
hence there is \( n \) such that

\[
\inf \{ d_n(A, A') : A \in \text{Supp}(F), A' \in \text{Supp}(G) \} > 0
\]
i.e. the images of \( \text{Supp}(F) \) and \( \text{Supp}(G) \) under \( A \mapsto L_n(A) := (A(e_0), \ldots, A(e_n)) \) are disjoint compact sets in \( \mathbb{R}^{n+1} \). We can find \( f, g \in C_c^\infty(\mathbb{R}^{n+1}) \) which have disjoint support, such that \( f = 1 \) on \( L_n(F) \) and \( g = 1 \) on \( L_n(G) \), and thus write

\[
F = F \times (f \circ L_n), \quad G = G \times (g \circ L_n)
\]
where \( \times \) is just pointwise multiplication. Therefore for \( F = q(A(f_0), \ldots, A(f_k)) \)

\[
DF = 2 \sum_{i \leq k} \partial_i(qf)(A(e_0), \ldots, A(f_k), A(e_0), \ldots, A(e_n)) f_i
\]

\[
\quad + 2 \sum_{i > k} \partial_i(qf)(A(e_0), \ldots, A(f_k), A(e_0), \ldots, A(e_n)) e_i
\]
and similarly for \( DG \). By direct inspection of (3.40) and (2.26), and the fact that \( \partial^\alpha f \partial^\beta g = 0 \) for any \( \alpha, \beta \in \{0, 1\} \), it follows that \( \mathcal{E}_X(F, G) = 0 \), i.e. \( \mathcal{E}_X \) is local (and so is its extension, see Theorem 3.1.2 in [FOT11]).

We also check strong locality. Let \( F \in \mathcal{C}_X \) with compact support \( K \subset X \), and \( G \in \mathcal{C}_X \) which is a constant say \( \overline{G} \in \mathbb{R} \) on a neighborhood \( U \) of \( K \). Since the topology of \( X \) is generated by the maps \( A \mapsto A(f_n) \), there is \( n \geq 0 \) and a neighborhood \( V \) of \( L_n(K) \) such that \( V \subset L_n(U) \). So

\[
G = g \circ L_n + (G - g \circ L_n)
\]
where \( g \) is constant \( \overline{G} \) on \( V \), and the second summand vanishes on a neighborhood of \( K \). By the previous argument and again by direct inspection of (3.40), (2.26), it follows that \( \mathcal{E}_X(F, G) = 0 \), i.e. \( \mathcal{E}_X \) is strongly local (and so is its extension, see Exercise 3.1.1 in [FOT11]). Strong locality expresses the absence of killing, see Theorem 4.5.3 in [FOT11].

A similar argument shows that \( \mathcal{C}_X \) is a special standard core (see I.1 in [FOT11]). Namely, for any compact set \( K \subset X \) and a relatively compact open set \( U \) with \( K \subset U \), one can construct an element \( F \in \mathcal{C}_X \) such that \( F \geq 0, F = 1 \) on \( K \) and \( F = 0 \) on \( X \setminus U \) by pulling back such a function on \( \mathbb{R}^{n+1} \) using the map \( L_n \).
3.3 Fukushima decomposition and weak solution

Coming back to our original problem, to give a meaning to a notion of weak solution to (1.8) or (1.10), for \( F = q(\int f_0 \omega_g, \ldots, \int f_k \omega_g) \) we use Itô’s formula and definition of \( \mathcal{L} \) to formally derive:

\[
dF = \sum_i 2 \partial_i q \cdot \left( \int f_i \Delta \phi \omega_0 - \lambda \int f_i \omega + \sigma \int f_i e^{\phi} \xi_0 \omega_0 \right) + 2\sigma^2 \sum_{i,j} \partial^2_{ij} q \int f_i f_j \omega_g
\]

\[
= \mathcal{L} F(\phi) dt + 2\sigma \sum_i \partial_i q \int f_i e^{\phi} \xi_0 \omega_0.
\]

In view of this, we say that a \( \mathcal{X} \)-valued process \( A_t \) is a weak solution to (1.10), if for any \( F(A) = q(A(f_0), \ldots, A(f_k)) \in C_X \) we have that \( M_t := F(A_t) - F(A_0) - \int_0^t \mathcal{L} F(A_s) ds \) is a martingale whose quadratic variation is

\[
\langle M \rangle_t = 4\sigma^2 \sum_{i,j=0}^{k} \int_0^t \partial_i q \partial_j q \cdot A_s(f_i f_j) \, ds.
\]

(3.45)

With the diffusion \( A = (\Omega, \mathcal{F}, (A_t), (P_z)) \) obtained above in Proposition 3.10, we prove that this \( A_t \) is a weak solution.

Recall that for such an \( F \in C_X \), the gradient is given by

\[
DF(A) = \sum_{i=1}^k \partial_i q(A(f_0), \ldots, A(f_k)) f_i
\]

(3.46)

so that \( DF \in C_X \otimes C^\infty(\Lambda) \).

Below we write \( AF \) for “additive functional”.

Let \( F \in C_X \), \( (A_t)_{t \geq 0} \) the process in \( \mathcal{X} \) associated to \( E \). We consider the continuous AF ([FOT11 Section 5.2])

\[
Y_t^{[F]} = F(A_t) - F(A_0).
\]

By [FOT11 Theorem 5.2.2], \( Y^{[F]} \) admits a unique Fukushima decomposition

\[
Y^{[F]} = M^{[F]} + N^{[F]} \quad (3.47)
\]

where \( M^{[F]} \) is a martingale AF of finite energy and \( N^{[F]} \) is a zero-energy continuous AF.

Namely, \( M^{[F]} \) is a finite càdlàg AF such that for each \( t > 0 \), \( \mathbb{E}_z(M_t^2) < \infty \) and \( \mathbb{E}_z(M_t) = 0 \) for quasi-every \( z \in \mathcal{X} \) where \( \mathbb{E}_z \) is the expectation for the measure \( P_z \), with energy

\[
e(M^{[F]}_t) := \lim_{t \to 0} \frac{1}{2t} \mathbb{E}_m[(M_t^{[F]})^2]
\]

being finite; and \( N^{[F]} \) is a finite continuous AF, with \( e(N^{[F]}) = 0 \) and \( \mathbb{E}_z[|N_t^{[F]}|] < \infty \) for quasi-every \( z \in \mathcal{X} \) for each \( t > 0 \).

In particular \( M^{[F]} \) admits a quadratic variation \( \langle M^{[F]} \rangle \) which is a positive continuous AF such that \( \mathbb{E}_z([\langle M^{[F]} \rangle]_t) = \mathbb{E}_z([M_t^{[F]}]^2) \) for quasi-every \( z \in \mathcal{X} \) and \( t > 0 \). For the quadratic variation \( \langle M^{[F]} \rangle \) we have the following lemma.
Lemma 3.11. Let $F \in C_X$ and $M^{[F]}$ be the martingale AF in (3.47). We have
\[
\langle M^{[F]} \rangle_t = \sigma^2 \int_0^t \| DF(A_s) \|_{L^2(A_s)}^2 ds .
\] (3.48)

Proof. The quadratic variation $\langle M^{[F]} \rangle$ is a positive AF, which is associated with a Revuz measure $\mu_{\langle M \rangle}$ via the Revuz correspondence ([FOT11, Section 5]). By [FOT11, Theorem 5.2.3], this Revuz measure has
\[
\mu_{\langle M \rangle}(G) = 2 \mathbb{E}_X(F \cdot G, F) - \mathbb{E}_X(F^2, G).
\]
From (3.46) we readily check that the Leibniz rule $D(FG) = F \cdot DG + G \cdot DF$ holds, which implies
\[
d\mu_{\langle M \rangle}(A) = \sigma^2 \| DF(A) \|_{L^2(A)}^2 dm(A).
\] (3.49)

Remark that with $F = q(\int f_1 dA, \ldots, \int f_k dA)$, the functional
\[
A \mapsto \| DF(A) \|_{L^2(A)}^2
\]
is also in $C_X$, and in particular continuous on $X$. It is then standard (for instance following the same lines as the proof of [AR91, Proposition 4.5]) to show that the Revuz measure corresponding to the right-hand side of (3.48) is also (3.49), thus the lemma follows.

To identify the diffusion as the weak solution we have the following more concrete representations (as required by (3.45)).

Lemma 3.12. For $F \in C_X$ with $F(A) = q(A(f_1), \ldots, A(f_k))$ we have
\[
\langle M^{[F]} \rangle_t = 4\sigma^2 \int_0^t \sum_{i,j} \partial_i q(A(f_1), \ldots, A(f_k)) \partial_j q(A(f_1), \ldots, A(f_k)) A_s(f_i f_j) ds .
\] (3.50)

In particular, for $F(A) = A(f)$ one has
\[
\langle M^{[F]} \rangle_t = 4\sigma^2 \int_0^t A_s(f^2) ds ,
\] (3.51)
and $M^{[F]}_t = 2\sigma \int_0^t (A_s(f^2))^{\frac{1}{2}} \, d\beta^f_s$ for a one-dimensional Brownian motion $\beta^f$ as required in (1.16).

Moreover, for $F = A(f)$ and $G = A(g)$ one has
\[
\langle M^{[F]}, M^{[G]} \rangle_t = 4\sigma^2 \int_0^t A_s(f g) ds .
\] (3.52)

Proof. By the calculation of $DF$ from (3.46) and Lemma 3.11 the claims (3.50) and (3.51) follow. Remark that $F(A) = A(f)$ is not in $C_X$ (not compactly supported); one obtains the desired result by standard truncation/localization arguments. The statement on identification of $M^{[F]}$ follows from the continuity of the AF $Y^{[F]}$ which implies continuity of $M^{[F]}$ together with martingale representation theorem.
Lemma 3.13. Let \( F \in C_X \) and \( N^{[F]} \) be the zero energy continuous AF in \( (3.47) \). We have
\[
N^{[F]}_t = \int_0^t \mathcal{L}F(A_s)ds \,.
\]
In particular, for \( F = A(f) \) one has \( N^{[F]}_t = 2 \int_0^t (\omega_0(f \Delta \phi_s) - \lambda A_s(f))ds \) with \( \phi_s = M^{-1}A_s \).

Proof. We have by integration by parts:
\[
\mathcal{E}(F,G) = \int Gd\nu_F
\]
where \( d\nu_F(A) = \mathcal{L}F(A)d\mathfrak{m}(A) \); here \( \nu_F \) has a locally integrable density with respect to \( \mathfrak{m} \) (actually integrable, see Lemma 2.5). By \cite{FOT11} Corollary 5.4.1, \( N \) is an AF with Revuz measure \( \nu_F \) (i.e. \( N = N^+ - N^- \) where \( N^\pm \) is a positive AF with Revuz measure \( \nu^\pm_F \)).

Since \( \mathcal{L}F \) is measurable on \( X \) locally compact, it can be approximated in \( L^p(\mathfrak{m}) \) by continuous functions. \( t \mapsto \mathcal{L}F(A_t) \) is an \( L^p \) limit of continuous adapted processes, hence is progressively measurable. In particular \( t \mapsto \int_0^t \mathcal{L}F(A_s)ds \) is well defined as a process and one can identify (arguing as in Example 5.1.1 of \cite{FOT11}).
\[
N_t = \int_0^t \mathcal{L}F(A_s)ds \,.
\]

Proof of Theorem 1.1. The claim of the theorem now immediately follows from Lemma 3.12 and Lemma 3.13.

Absorption. Let \( A_t(1) = \int_A A_t(dx) \) be the total volume of the torus \( \Lambda \). By applying these results we have:

Corollary 3.14. The process \( (A_t(1))_{t \geq 0} \) is a.s. absorbed at 0 in finite time.

Proof. Consider the function \( f \equiv 1 \); one then obtains a simple autonomous SDE satisfied by \( A_t(1) \)
\[
dA_t(1) = 2 \left( \int \phi_t(\Delta 1) dA_0 - \lambda A_t(1) \right) dt + 2\sigma \sqrt{A_t(1)} d\beta_t
\]
\[
= 2\sigma \sqrt{A_t(1)} d\beta_t - 2\lambda A_t(1) dt
\]
where \( \beta \) is a 1-dimensional Brownian motion. One recognizes the evolution of a continuous-state branching process (CSBP), which is also continuous in time. A solution for \( \lambda \geq 0 \) is stochastically dominated by a solution for \( \lambda = 0 \). Setting \( \lambda = 0 \), one further recognizes the SDE satisfied by a square Bessel process of dimension 0 (BESQ(0), also known as the Feller diffusion). That process is a.s. absorbed at 0 in finite time.
Consequently, recalling that we have defined $X := \mathcal{M}(\Lambda) \setminus \{0\}$, the lifetime $\zeta$ in (3.44) is a.e. finite; the process evolves continuously in $X$ until it is absorbed at 0, which occurs in finite time. Alternatively we can consider $\mathcal{M}(\Lambda)$ itself as the state space, and then 0 is an absorbing state.

4 Extensions

4.1 Compact surfaces

According to the discussion below (1.5), it seems natural to try to construct a SRF of the form

$$\partial_t \phi \equiv -K_g - \lambda + \sigma \xi_g = e^{-2\phi}(\Delta \phi - K_0) - \lambda + \sigma \xi_g$$

so that for $A = e^{2\phi}\omega_0$: we expect the following one dimensional projection (compare with (1.17))

$$dA_t(f) \equiv 2\left(\omega_0(f \Delta \phi_t) - \omega_0(f K_0 - \lambda A_t(f))\right)dt + 2\sigma (A_t(f^2))^{\frac{1}{2}} d\beta_t$$

and for $F = q(A(f_1), \ldots, A(f_n))$ (compare with (3.38))

$$\mathcal{L}F(\phi) \equiv \sum_i 2\partial_i q \cdot \left(\omega_0(f_i \Delta \phi) - \omega_0(f_i K_0 - \lambda A(f_i))\right) + 2\sigma^2 \sum_{i,j} \partial^2_{ij} q \cdot A(f_i f_j) .$$

However this formal derivation fails to correctly account for the “quantum” correction in Liouville CFT, as we shall explain momentarily.

Here we follow closely [GRV16b], which we refer to for a detailed treatment; recall the convention comparison of (1.14). Consider a surface $\Sigma$ with reference metric $g_0$ and the action (see (2.2) in [GRV16b])

$$S_L(g_0, X) = \frac{1}{4\pi} \int (|\nabla X|^2 + 2Q K_0 X + 4\pi \mu e^\gamma X) \omega_0$$

where

$$Q = \frac{2}{\gamma} + \frac{\gamma}{2}$$

(note that [GRV16b] uses $K$ for scalar curvature, which equals twice the Gauss curvature, and uses $\varphi$ for twice the conformal factor $\phi$).

This induces the measure on fields (see (3.1) in [GRV16b])

$$d\nu_{g_0}(X) = \exp(-S_L(g_0, X)) DX = e^{-\frac{1}{4\pi} \int (2Q K_0 X + 4\pi \mu e^\gamma X) \omega_0} \left(\int |\nabla X|^2 \omega_0 DX\right)$$

where $DX$ is the formal flat measure on fields. The last bracket is interpreted as a $\sigma$-finite measure on paths as in (2.18), viz. as the sum of a zero-mean GFF and a “Lebesgue-distributed” constant; the rest of the action is then an almost everywhere defined Radon-Nikodym derivative. The quadratic part is characterized, up to multiplicative constant, by the Cameron-Martin formula:

$$\left(e^{-\frac{1}{4\pi} \int |\nabla(X+h)|^2 \omega_0} \mathcal{D}(X + h)\right) = e^{-\frac{1}{4\pi} \int \nabla X \cdot \nabla h \omega_0 - \frac{1}{2\pi} \int |\nabla h|^2 \omega_0} \left(e^{-\frac{1}{4\pi} \int |\nabla X|^2 \omega_0} DX\right)$$

(4.56)
for \( h \in H^1(\Sigma) \), as in Lemma 2.4.

Indeed, remark that, from the local nature of the Liouville measure, there is no difficulty in constructing it on surfaces along the following lines: cover \( \Sigma \) by finitely many complex disks \( (U_i)_{1 \leq i \leq n} \); for any \( V \subset U_i \), the restriction of the zero-mean GFF to \( V \) is absolutely continuous w.r.t. to the zero-boundary GFF on \( U_i \). Then one can define the Liouville measure on each \( U_i \) and patch them together. Moreover one can assume that each \( U_i \) carries isothermal coordinates. Alternatively one can retrace the steps of the planar construction and check that it carries over to surfaces. One also has the basic moment estimates used in Lemma 2.5.

Let \( \hat{g}_0 = e^{2\psi_0}g_0 \) be another reference metric with volume form \( \hat{\omega}_0 \). Then the GMC regularization introduces the following anomalous scaling (see (3.12) in [GRV16b]):

\[
\hat{e}^{\gamma \hat{X}} \hat{\omega}_0 := e^{(2+\gamma^2/2)\psi_0} \cdot e^{\gamma \hat{X}} \omega_0 \cdot g_0
\]

i.e. \( :e^{\gamma \hat{X}} \hat{\omega}_0 :g_0 = :e^{\gamma \hat{X}} \omega_0 :g_0 \) if \( \hat{X} = X - Q\psi_0 \) (here \( :g_0 \) denotes the limit of an \( \varepsilon \)-regularization scheme such as (1.11) where \( \varepsilon \) is measured in \( g_0 \)).

We have the conformal anomaly (Proposition 4.2 in [GRV16b])

\[
\int F(X) d\nu_{g_0}(X) \propto \int F(X - Q\psi_0) d\nu_{g_0}(X)
\]

and consequently the pushforward of \( \nu_{g_0} \) by \( X \mapsto M_X \) \( \text{def} :e^{\gamma \hat{X}} \omega_0 :g_0 \) (a \( \sigma \)-finite measure on \( \mathcal{X} := \mathcal{M}(\Sigma) \setminus \{0\} \)) does not depend (up to multiplicative constant) on the choice of reference metric \( g_0 \), just on the Riemann surface structure of \( \Sigma \). This justifies the choice of (4.55) in the definition of the action (4.54). Let us denote that measure by \( m \).

We have the integration-by-parts formula:

\[
4\pi \int D_h F(X) d\nu_{g_0}(X) = \int F(X) \left( 2\omega_0 \left( \nabla_0 h \cdot \nabla_0 X + QK_0 h \right) + 4\pi \mu \gamma M_X(h) \right) d\nu_{g_0}(X)
\]

derived from (4.56) along the same lines as Theorem 2.6.

Similarly to (2.23) and (2.24), one can define test functionals and evaluate their Fréchet derivatives as follows: if \( M_X = :e^{\gamma \hat{X}} \omega_0 :g_0 \) and \( F \) is a test functional of the form

\[
F(X) = q(M_X(f_1), \ldots, M_X(f_k))
\]

where the \( f_i \)'s are smooth on \( \Sigma \) and \( q : \mathbb{R}^k \to \mathbb{R} \) is smooth, the Fréchet derivative of \( F \) in the smooth direction \( h \) is

\[
D_h F(X) = \gamma \sum_i \partial_i q(M_X(f_1), \ldots, M_X(f_k)) M_X(hf_i)
\]

Similarly to (2.26), the gradient \( DF \) of \( F \) w.r.t. to the Liouville \( L^2 \) norm is thus given by

\[
DF(X) = \gamma \sum_i \partial_i q(M_X(f_1), \ldots, M_X(f_k)) f_i
\]
From the study of the torus case, it is at this stage natural to take as starting point the following Dirichlet form:

$$\mathcal{E}(F,F) = \int \|DF\|_{L^2(M_X)}^2 d\nu_0$$

which depends on the choice of reference metric $g_0$ only through a multiplicative constant. Running the computation of Lemma 3.4 in reverse order, we have (write $\nu = \nu g_0$)

$$\mathcal{E}(F,F) = \int \|DF(X)\|_{L^2(M_X)}^2 d\nu(X)$$

$$= \gamma^2 \sum_{i,j} \partial_i q \partial_j q M_X(f_i f_j) d\nu(X)$$

$$= \sum_{i} D_{f_i}(q \partial_i q) - \gamma \sum_{i,j} q \partial^2_{ij} q M_X(f_i f_j) d\nu(X)$$

$$= - \int q \left( \sum_{i} \partial_i q \cdot \left( \frac{\gamma}{2\pi} \omega_0(f_i \Delta X) - \frac{Q \gamma}{2\pi} \omega_0(f_i K_0) - \mu \gamma^2 M_X(f_i) \right) 
+ \gamma^2 \sum_{i,j} \partial^2_{ij} q M_X(f_i f_j) \right) d\nu(X)$$

$$= \int F(-\mathcal{L}F) d\nu(X)$$

where

$$\mathcal{L}F = \gamma^2 \sum_{i,j} \partial^2_{ij} q M_X(f_i f_j) + \sum_{i} \partial_i q \left( \frac{\gamma}{2\pi} \omega_0(f_i \Delta X) - \frac{Q \gamma}{2\pi} \omega_0(f_i K_0) - \mu \gamma^2 M_X(f_i) \right)$$

More generally, we have

$$\mathcal{E}(F,G) = \int \langle DF(X), DG(X) \rangle_{L^2(M_X)} d\nu(X) = \int F(-\mathcal{L}G) d\nu(X)$$

This corresponds to the formal dynamics (compare with (1.10))

$$\partial_t \omega = \frac{\gamma}{2\pi} \Delta \phi \omega_0 - \frac{Q \gamma}{2\pi} K_0 \omega_0 - \mu \gamma^2 \omega + \gamma \sqrt{2} \xi \omega$$

(4.58)

or the 1d dynamics (compare with (1.16))

$$d\omega(f) = \left( \frac{\gamma}{2\pi} \omega_0(f \Delta \phi) - \frac{Q \gamma}{2\pi} \omega_0(f K_0) - \mu \gamma^2 \omega(f) \right) dt + \sqrt{2} \gamma \sqrt{\omega(f^2)} d\beta_t^f$$

for $f$ a smooth function on $\Sigma$.

In particular for $f \equiv 1$ (taking into account Gauss-Bonnet: $\int_{\Sigma} K_0 \omega_0 = 2\pi \chi$, where $\chi = 2 - 2g$ is the Euler characteristics of $\Sigma$), we see that the total volume $\omega_t(1)$ evolves as:

$$d\omega_t(1) = \gamma \sqrt{2} \sqrt{\omega_t(1)} d\beta_t - \mu \gamma^2 \omega_t(1) dt - Q \gamma \chi dt$$

(4.59)
where $\beta$ is a one-dimensional Brownian motion.

Up to replacing $\gamma X$ (LQFT convention) with $2\phi$ (earlier convention) and matching parameters (see (1.14)), this differs from the naive guess (4.53) by a factor $Q\gamma/2 = 1 + \gamma^2/4$ in front of the curvature. Namely, the right dynamic should be:

$$\partial_t \phi = e^{-2\phi} (\Delta \phi - (1 + \frac{\gamma^2}{4}) K_0) - \lambda + \sigma \xi .$$

The discrepancy can be explained as follows: the formal derivation of (4.53) interprets the Liouville measure as a 2-form, whereas it transforms as a $Q\gamma$-form (see (4.57)).

### 4.2 Insertions

In the context of LCFT, it is natural to consider insertions of “vertex operators”. We sketch here the modifications needed to incorporate insertions in the SRF framework.

As before, $\Sigma$ is a compact Riemann surface; additionally, we assign real weights $\alpha_1, \ldots, \alpha_k$ to marked points $x_1, \ldots, x_k$. Associated to this data, we consider the formal dynamics (compare with (4.58))

$$\partial_t A = \frac{\gamma}{2\pi} \Delta \phi \omega_0 - \frac{Q\gamma}{2\pi} K_0 A_0 - \mu \gamma^2 A + \gamma \sqrt{2} \xi A + \gamma \sum_{i=1}^k \alpha_i \delta_{x_i}$$

and the corresponding 1d dynamics for $f$ a smooth function on $\Sigma$:

$$dA_t(f) = \left( \frac{\gamma}{2\pi} \omega_0 (f \Delta \phi) - \frac{Q\gamma}{2\pi} \omega_0 (f K_0) - \mu \gamma^2 A_t(f) \right) dt + \gamma \sqrt{2} (A_t(f^2))^{1/2} d\beta_t^f + \gamma \sum_{i=1}^k \alpha_i f(x_i) dt$$

For a reference metric $g_0$ on $\Sigma$, consider the measure on fields, written for now formally as

$$d\nu_{g_0}^\alpha(X) = \left( \prod_{i=1}^k e^{\alpha_i X(x_i)} \right) d\nu_{g_0}(X)$$

Note that the term in brackets is not a Radon-Nikodým derivative. Admit for now the conformal anomaly formula

$$\int F(X) d\nu_{g_0}^\alpha(X) \propto \int F(X - Q\psi_0) d\nu_{\tilde{g}_0}^\alpha(X)$$

(here $\tilde{g}_0 = e^{2\psi_0} g_0$; the coefficient of proportionality depends on the $\alpha_i$’s), and the integration-by-parts formula

$$\int D_h F(X) d\nu_{g_0}^\alpha(X)$$

$$= \int F(X) \left( \frac{1}{2\pi} \langle \nabla_0 h, \nabla_0 X \rangle_{g_0} + \frac{Q}{2\pi} \omega_0 (K_0 h) + \mu \gamma M_X(h) - \sum_i \alpha_i h(x_i) \right) d\nu_{g_0}^\alpha(X)$$

28
Given this, one can consider the Dirichlet form

\[ \mathcal{E}(F, F) = \int \|DF\|^2_{L^2(A)} d\nu^\alpha_{g_0} = \int F(-\mathcal{L}F) d\nu^\alpha_{g_0}(X) \]

where

\[ \mathcal{L}F = \gamma^2 \sum_{i,j} \partial^2_{ij}qA(f_i f_j) + \sum_i \partial_i q \left( \frac{\gamma}{2\pi} \omega_0(f_i \Delta X) - \frac{Q \gamma}{2\pi} \omega_0(f_i K_0) - \mu \gamma^2 A(f_i) + \gamma \sum_j \alpha_j f_i(x_j) \right) \]

which realizes the desired dynamics (4.60).

We refer to [GRV16b] for a construction of \( \nu^\alpha_{g_0} \) with the desired properties (viz. anomaly and integration by parts); concretely, it can be realized as a vague limit of measures absolutely continuous w.r.t. \( \nu_{g_0} \):

\[ d\nu^\alpha_{g_0}(X) = \lim_{\varepsilon \to 0} \left( \prod_i \varepsilon^{\alpha_i^2} e^{\alpha_i X_{\varepsilon}(x_i)} \right) d\nu_{g_0}(X) \]

where \( X_{\varepsilon} \) denotes a mollification of \( X \) on scale \( \varepsilon \). This requires the following local Seiberg bound:

\[ \alpha_i < Q \]

for \( i = 1, \ldots, k \) (remark that here we are not concerned with finiteness of \( \nu^\alpha_{g_0} \)).

The total mass \( (A_t(1)) \) satisfies an SDE with generator

\[ \gamma^2 x \partial_{xx} - \mu \gamma^2 x \partial_x + \gamma (\bar{\alpha} - Q\chi) \partial_x \]

where \( \bar{\alpha} = \sum_i \alpha_i \). The term with \( \mu \) does not change qualitatively the behavior at 0. Setting \( \mu = 0 \), the generator is proportional to that of a BESQ(\( \delta \)), viz. \( 2x \partial_{xx} + \delta \partial_x \), where

\[ \delta = \frac{2}{\gamma} (\bar{\alpha} - Q\chi) . \]

If \( \delta \geq 2 \), the process does not hit 0 (but can be started from 0). If \( \delta \in (0, 2) \), the process hits 0, but can be continued. If \( \delta \leq 0 \), 0 is absorbing. The global Seiberg bound is \( \bar{\alpha} - Q\chi > 0 \), i.e. \( \delta > 0 \); together with the local Seiberg bounds (\( \alpha_i < Q \)), it ensures finiteness of \( \nu^\alpha \), see [GRV16b]. Since 0 \( \notin \mathcal{X} \) by definition, the SRF is by construction absorbed at 0. However, this suggests that if \( \delta \in (0, 2) \), the SRF can be extended to a process on \( \mathcal{X} \cup \{0\} \), with infinite lifetime (i.e. conservative).

## 5 Questions and open problems

**Regularity.** In the 2d Stochastic Heat Equation \( \partial_t \phi_t = \Delta \phi_t + \xi \), the solution can be realized as an element of \( C([0, T], H^{-s}) \) for any \( s > 0 \), i.e. \( t \mapsto \phi_t \) is a.s. continuous w.r.t. a Banach space topology.
For a Stochastic Ricci Flow \((\phi_t, A_t)\), we know that the second marginal \(t \mapsto A_t\) evolves a.s. continuously w.r.t. to the weak topology on \(\mathcal{X}\).

**Question 1.** Strengthen the regularity of the second marginal, e.g. show that \(t \mapsto A_t\) is continuous a.s. in a Besov space topology. Note that \([\text{GRV16a}]\) has proved a Hölder continuity result for the GMC \(M_\gamma\) with \(\gamma \in [0, 2)\) on the torus: for any \(\varepsilon > 0\), almost surely there is a (random) constant \(C\) depending on \(\varepsilon\) and the Gaussian free field, such that \(M_\gamma(B(x, r)) \leq Cr^{\alpha-\varepsilon}\) with \(\alpha = 2(1 - \frac{\gamma}{2})^2\) for any ball \(B(x, r)\). We also note that the space-time regularity (with respect to a parabolic distance) of the GMC \(M_\phi\) when the field \(\phi\) evolves according to stochastic heat equation is obtained in \([\text{Gar18}]\).

**Question 2.** Is the first marginal a.s. continuous w.r.t. an abstract Wiener space topology? (e.g., \(H^{-s}\) for some \(s\))

**Feller property.** The Dirichlet form formalism provides a family of probability measures on path space \((P_z)_{z \in \mathcal{X}}\) indexed by starting state \(z \in \mathcal{X}\); this family is uniquely defined except possibly on an exceptional set of starting states (see Theorem 4.2.7 in \([\text{FOT11}]\)). This exceptional set is in particular \(m\)-negligible.

**Question 3.** Define \(P_z\) unambiguously for all \(z \in \mathcal{X}\).

This can be thought of as an entrance problem. Concretely, if \((U_n)\) is a sequence of shrinking neighborhoods of \(z \in \mathcal{X}\), one would expect \((P_{m(\cdot \mid U_n)})_n\) to converge weakly as \(n \to \infty\) (w.r.t. to the Skorohod space topology on \(C([0, \infty), \mathcal{X} \cup \{0\})\)).

**Question 4.** Is the Stochastic Ricci Flow strong Feller? (w.r.t. to a topology on \(A\) or \((\phi, A)\))

Here it may be useful to have more explicit control on the map \(M^{-1}\) (see (3.37)).

**Entrance and reflection.** It follows from strong locality (proof of Proposition 3.10) that, on the event that the lifetime \(\zeta\) is finite, the total mass \((A_t(1))\) goes to 0 or \(\infty\) as \(t \nearrow \zeta\). The latter is ruled out by the autonomous SDE satisfied by the mass (see (4.59)), and the former happens a.s. iff \(\delta = \frac{2}{\gamma}(\bar{\alpha} - Q\chi) < 2\) (see the discussion at the end of Section 4.2). By construction (i.e., the choice of state space and core), the process is absorbed at 0 (and hence not conservative if it hits zero in finite time). The symmetrizing measure \(m\) is invariant for the semigroup if the semigroup is conservative. By comparison of the total mass process with BESQ(\(\delta\)), it is natural to ask:

**Question 5.** In the case \(\delta \geq 2\), is 0 an entrance boundary? viz., can the SRF be extended to a Feller process on \(\mathcal{X} \cup \{0\}\), that a.s. never returns to 0?

**Question 6.** In the case \(\delta \in (0, 2)\), can the SRF be extended to a process reflected at 0? i.e. a conservative process such \(\{t : A_t(1) = 0\}\) has a.s. zero Lebesgue measure.

If one starts with \(\mathcal{X} := \mathcal{X} \cup \{0\}\) as state space, the difficulty is to define a core \(C_\mathcal{X}\) dense in \(C_0(\mathcal{X})\), such that integration by parts (3.40) still holds.

**Approximation schemes.** Fix two small parameters \(\delta, \varepsilon\). Based on (1.9), it is natural to consider the following scheme: on the time interval \(t = [k\delta, (k + 1)\delta)\), solve the linear SHE with smooth coefficients (here in the torus case)

\[\partial_t \phi_t = \varepsilon^\alpha e^{-2\phi_t} \Delta_0 \phi_t + \sigma\varepsilon^\beta e^{-\phi_t} \xi_0\]
Here $\phi^\varepsilon$ denotes an $\varepsilon$-mollification of $\phi$. Remark that, if $\phi_0$ is absolutely continuous w.r.t. to the GFF (2.18), then for all $t$, $\phi_t$ is also absolutely continuous w.r.t. the same GFF. This is a natural analogue of frozen coefficients approximations for SDEs.

**Question 7.** Does this scheme converge to SRF as $(\delta,\varepsilon) \to (0,0)$ in some way, for suitable renormalization exponents $(\alpha,\beta)$?

Showing directly the convergence of such a scheme could provide an alternative proof of existence and shed some light on the previous regularity questions.

**Question 8.** Find a Wong-Zakai approximation for small $\sigma$.

Here one considers $\xi^\varepsilon$, a space-time $\varepsilon$-mollification of the white noise $\xi$; then one solves classically

$$\partial_t \phi^\varepsilon = \varepsilon^\alpha e^{-2\phi^\varepsilon} \Delta \phi - \lambda + \varepsilon^\beta \sigma e^{-\phi^\varepsilon} \xi^\varepsilon + \text{(counterterms)}$$

and attempts to take a limit in probability as $\varepsilon \downarrow 0$, for suitable normalization exponents $(\alpha,\beta)$ and - possibly - counterterms.

**Strong solutions.** It is not immediately apparent how to phrase a notion of strong solutions for SRF. The previous approximation schemes (for fixed $\varepsilon > 0$) are measurable with respect to a fixed white noise $\xi_0$.

**Question 9.** Show almost sure convergence of an approximation scheme, for a fixed realization of $\xi_0$.

Formally, the SRF in terms of $\phi$ (1.8) is a quasilinear singular stochastic PDE. Strong solution theories for such quasilinear stochastic PDEs are under rapid progress. In [OW18], strong solutions to equations of the form (up to technical subtleties such as a mean-zero component projection therein) $\partial_t u = a(u) \partial_x^2 u + \sigma(u) f$ for random forcing $f \in C^{\alpha-2}$ with $\alpha > \frac{2}{3}$ are constructed using controlled rough paths theory. Here $C^\alpha$ is a space-time Hölder regularity defined with respect to a parabolic distance, see [OW18, Section 2]. The solution lies in the space $C^\alpha$ and is the limit of a sequence of suitably renormalized equations driven by smooth mollified noises (that is, $f$ convolved with smooth mollifiers). Note that $\alpha = 1$ is the borderline where the products $a(u) \cdot \partial_x^2 u$ and $\sigma(u) \cdot f$ fail to have a classical meaning.

The key idea that allows [OW18] to generalize the strong solution theories such as [Hai14] that was originally applied to study semilinear equations is a parametric ansatz; one builds solution to a family of linear equations $\partial_t v = a_0 \partial_x^2 v + f$ parametrized by constants $a_0$, as well as higher order terms $vf$ and $v \partial_x^2 v$. The input $(v,vf,v \partial_x^2 v)$, once constructed by stochastic methods, is sufficient to render a PDE theory as long as $\alpha > \frac{2}{3}$, because the “error” of replacing $a(u)$ or $\sigma(u)$ by $v$ is order $2\alpha$ and $2\alpha + (\alpha - 2) > 0$ is the key condition for PDE estimates. Similar results have been obtained by [FG19, BDH19] also for $\alpha > \frac{2}{3}$, but using the para-controlled approach (originally developed in [GIP15]).

The work by [GH17] then generalized the above results by building a framework for construction of local renormalized solutions to general quasilinear stochastic PDEs within the theory of regularity structures. It exploited a series of existing results developed for the semilinear case such as [BH16, BCC17, CH16] so that it only requires a small number of additional arguments to extend to the quasilinear setting. As applications an equation of the form $\partial_t u = a(u) \partial_x^2 u + F(u)(\partial_x u)^2 + \sigma(u) f$ is considered...
where \( f \in \mathcal{C}^{\alpha-2} \) with \( \alpha > \frac{1}{2} \). There is also [OSSW] under a twisted version of regularity structure framework which works for \( \alpha > \frac{1}{2} \). With extra work, one may expect to push the regularity down to \( \alpha > \frac{2}{5} \) by building more “perturbative” information so that \( 4\alpha + (\alpha - 2) > 0 \). But this would eventually cease to work at \( \alpha = 0 \) and the SRF should be as singular as the two-dimensional GFF, i.e. \( \alpha < 0 \). Note that spatial dimension is two for SRF here, but the obstacle here is regularity rather than dimension (some of the aforementioned papers work or can be adapted to more than one dimension.)

Alternatively, one can attempt to construct a solution as a small noise expansion (e.g. in powers of \( \sigma \)); the terms in the expansion are then measurable with respect to a standard white noise \( \xi_0 \).

Note that Takhtajan [TT06] defines Liouville CFT via perturbative expansion (in Planck constant) around the classical solution \( \phi_{cl} \) to the Liouville equation. It is not clear to us how to “translate” his works to the dynamic setting. However, here are some thoughts. Consider again (1.8). We can try to write the solution \( \phi \) as a series in \( \sigma \):

\[
\phi = \sum_{i=0}^{\infty} \sigma^i \phi_i .
\]

We can show that each \( \phi_i \) satisfies an equation that is linear in \( \phi_i \), and only depending on the \( \phi_j \) \((j < i)\). In particular,

\[
\partial_t \phi_0 = e^{-2\phi_0} \Delta \phi_0 - \lambda
\]

which is the classical Ricci flow, and a stationary solution (set \( \partial_t \phi_0 = 0 \)) is the solution to the classical Liouville equation. Also,

\[
\begin{align*}
\partial_t \phi_1 &= e^{-2\phi_0} \Delta \phi_1 - 2e^{-2\phi_0} \phi_1 \Delta \phi_0 + e^{-\phi_0} \xi_0 \\
\partial_t \phi_2 &= e^{-2\phi_0} \Delta \phi_2 + 2e^{-2\phi_0} (\phi_1^2 - \phi_2) \Delta \phi_0 - 2e^{-2\phi_0} \phi_1 \Delta \phi_1 - e^{-\phi_0} \phi_1 \xi .
\end{align*}
\]

Note that the second order operator in each of the equations is \( \partial_t - e^{-2\phi_0} \Delta \). This seems close to the spirit of Takhtajan [TT06] who takes \((e^{-2\phi_{cl}} \Delta + m^2)^{-1}\) as the “free propagator” in his Feynman diagram expansion.

**Question 10.** Can one define a series solution via small noise expansions?
