**Key Words**

*Pistacia lentiscus* oil • Stomach • Liver • Kidney • Blood • Cytochrome P450s

**Abstract**

**Background:** *Pistacia lentiscus* (Anacardiaceae) is a flowering plant traditionally used in the treatment of various skin, respiratory, and gastrointestinal disorders. The aim of this study was to assess whether *Pistacia lentiscus* oil has any short term toxic effects *in vivo* and *in vitro*.

**Methods:** *Pistacia lentiscus* oil (100 µl) was administered orally into mice for 5 days. **Results:** Measurements of body weight did not show any weight loss. Serum concentration of LDH did not show any significant statistical difference when compared to control mice. Similarly, blood, kidney or liver function tests showed no toxicity with *Pistacia lentiscus* oil when compared to the control group. Examination of gastrointestinal tissues sections revealed similar structural features with no difference in cell proliferation. In this context, pharmacological dilutions of *Pistacia lentiscus* oil (10\(^{-6}\) - 10\(^{-3}\)) did not affect the viability (cell death and proliferation) of mouse gastric stem cells, human colorectal cancer cells HT29, human hepatoma cells HepG2. However, it appears that at the dose and time point studied, *Pistacia lentiscus* oil treatment has targeted various cytochrome P450s and has specifically inhibited the activities and the expression of CYP2E1, CYP3A4, CYP1A1 and CYP1A2 differentially in different tissues. Our results also demonstrate that there is no appreciable effect of *Pistacia lentiscus* oil on the GSH-dependent redox homeostasis and detoxification mechanism in the tissues. **Conclusion:** These data suggest a good safety profile of short term oral use of *Pistacia lentiscus* oil as a monotherapy in the treatment of various skin, respiratory, and gastrointestinal disorders. However, due to its inhibitory effect of various cytochrome P450s and mainly CYP3A4, this might have implications on the bioavailability and metabolism of drugs taken in combination with *Pistacia lentiscus* oil. More attention is needed when *Pistacia lentiscus* oil is intended to...
be uses in combination with other pharmacological agents in order to avoid potential drug-drug interaction leading to toxicity. This study will help in safer use of *Pistacia lentiscus* oil for therapeutic purpose.

**Introduction**

*Pistacia lentiscus* L. (Anacardiaceae) is a flowering plant which grows in Mediterranean area. It is traditionally used in the treatment of several diseases, e.g. eczema, throat infections, diarrhea, renal stones, jaundice, asthma and gastric ulcer [1]. Mastic oil, the essential oil of mastic gum, a natural resin obtained from *Pistacia lentiscus* has a wide-range of therapeutic effects: anti-inflammatory, antibacterial, antifungal, antiviral, anticancer, and hypolipidemic activities [2-13]. *Pistacia lentiscus* is also effective in the treatment of functional dyspepsia and gastric ulcer [14-16] as well as in the healing of burns [17]. Because of its special taste, since antiquity *Pistacia lentiscus* has been extensively used in the Mediterranean and Middle Eastern countries as food/beverages flavouring additive and also as a traditional medicine without any reported toxicity [6]. However, a toxicological study showed that dietary treatment with mastic gum at the high dose for 13 weeks decreased body weights, and also increased liver weights [18]. In traditional medicine *Pistacia lentiscus* oil is used for a short period of time (3 to 5 days) to treat throat infections, skin rash, or functional dyspepsia. However, the safety profile of this short term use of *Pistacia lentiscus* has not been reported so far.

Therefore, the aim of this study was to assess *in vivo* the safety of *Pistacia lentiscus* oil after a short five days oral administration.

**Materials and Methods**

**Ethics Statement**

This project was reviewed and approved by our Institutional Review Board in compliance with College of Medicine & Health Sciences, national and international laws and policies (EEC Council Directive 86/609, OJ L 358, 1, December 12, 1987; and NIH Guide for Care and Use of Laboratory Animals, NIH Publication No. 85-23, 1985) and the experiments were performed in accordance with protocols approved by the College of Medicine & Health Sciences Animal Ethics Committee, United Arab Emirates University, Al-Ain, United Arab Emirates.

**Treatment of animals with Pistacia lentiscus**

Six-week-old female TO-mice (HsdOla: TO, Harlan, UK) weighing 20 to 25 g were used. Mice (five to seven in each group) were housed in 12-h light/12-h dark cycle and temperature-controlled (22 ± 1°C) room. They had free access to commercial laboratory chow and were provided with tap water ad libitum. Mice were treated by daily oral gavage of 100 µl *Pistacia lentiscus* oil for five consecutive days. Control group received 100 µl of saline solution orally. This protocol was repeated three times and the mice were monitored every day for their weight and any sign of toxicity.

**Oil extraction from Pistacia lentiscus fruits**

*Pistacia lentiscus* fruits were collected in Jijel region, Algeria and the oil was extracted from the fruits as previously reported [17]. This study was carried out on private land and the owner of the land gave permission to conduct the study on this site. Briefly, the fruits were air dried in the shade, and then oil was extracted by traditional cold-pressure in different steps. The fruits were ground into a paste, mixed for 30 mins, spread on fiber disks and then pressed. Cold water was run down the sides of the disks to increase the filtration of the oil. The liquids were then separated by decantation. At the end of this phase, Virgin *Pistacia lentiscus* oil was produced [17]. The chemical composition of the oil extracted from *Pistacia lentiscus* fruits is dominated by two monoterpenic hydrocarbons: alpha-Pinene (37.9-51.5%) and Myrcene (27-69.7%),
which suggest that the pharmacological effects of *Pistacia lentiscus* oil are mainly mediated by these two compounds [19].

**Chemicals and kits for toxicities**

NADH, NADPH, 1-chloro-2, 4-dinitrobenzene (CDNB), dithionitrobenzoic acid, dimethylnitrosamine (DMNA), erythromycin, 7-ethoxyresorufin, 7-methoxyresorufin, glutathione (GSH), oxidized glutathione (GSSG), glutathione reductase, cumene hydroperoxide, thiobarbituric acid and malondialdehyde were purchased from Sigma-Aldrich Fine Chemicals (St Louis, MO, USA). 2′, 7′-Dichlorofluorescein diacetate (DCFDA) and lucigenin were from Molecular Probes (Eugene, OR, USA). Polyclonal antibodies against CYP 2E1, CYP 3A4, CYP1A1 and CYP 1A2 were purchased from Amersham Int. Plc. (Amersham, UK) and β-actin from Santa Cruz Biotech (Santa Cruz, CA, USA). Reagents for SDS-PAGE and Western blot analyses were purchased from BioRad (Milwaukee, USA).

**Effect of *Pistacia lentiscus* oil on blood, liver, and kidney functions**

Blood was taken from the abdominal aorta for hematology and blood chemistry analysis. Hematological examinations were performed for the following parameters: white blood cell count (WBC), red blood cell count (RBC), hemoglobin concentration (HGB), hematocrit (HCT), platelet count, mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC) using an ABX VET ABC Hematology Analyzer with a mouse card (ABX Diagnostics, Montpellier, France). Serum biochemistry was performed for the following parameters: aspartate aminotransferase (AST), alanine aminotransferase (ALT), creatinine, blood urea nitrogen (BUN) and lactate dehydrogenase (LDH) using standard laboratory methods with an LX20 multiple automated analyzer (Beckman Coulter, CA, USA).

**Impact of *Pistacia lentiscus* oil on the gastrointestinal tract cellular proliferation**

To label dividing progenitor/stem cells in the S phase of the cell cycle, some of the control and treated mice were injected with bromodeoxyuridine (BrdU, 120 mg/kg body weight) 1 hour before sacrifice. Three regions (stomach, small intestine and colon) of the gastrointestinal tract of control and treated mice were processed for histological examination and immunohistochemical analysis as previously mentioned [20]. The proliferative capability and location of these progenitor/stem cells in the gastrointestinal epithelium were previously characterized and well established [20, 22]. Tissues were immediately fixed overnight in Bouin solution. Tissues were then dehydrated in ethanol, cleared in xylene and embedded in paraffin. For general morphological examination, control and treated tissue sections were stained with hematoxylin and eosin. Some sections were also probed with goat anti-BrdU antibodies. Antigen-antibody binding sites were visualized by incubating the tissue sections with peroxidase-conjugated donkey anti-goat immunoglobulin G and then with diaminobenzidine.

**Impact of *Pistacia lentiscus* oil on Cellular viability (cell death and proliferation) of gastrointestinal cell in vitro**

Mouse gastric stem cells MGSC [21], human colorectal cancer cells HT29, and human hepatoma cells HepG2 were maintained in DMEM (Invitrogen, Paisley, UK). All media were supplemented with antibiotics (penicillin 50U/ml; streptomycin 50 µg/ml) (Invitrogen, Cergy Pontoise, France) and with 10% fetal bovine serum (FBS, Biowest, Nouaille, France). Cells were seeded at a density of 5,000 cells / well into 96-well plates. After 24 h, cells were treated for another 24 and 48h with different dilutions of *Pistacia lentiscus* oil (10⁻⁶ - 10⁻³), in triplicate. *Pistacia lentiscus* oil was well dissolved in DMEM media. Control cultures were treated with 0.1% DMSO. The effect of *Pistacia lentiscus* oil on cell viability was determined using a CellTiter-Glo Luminescent Cell Viability assay (Promega Corporation, Madison), based on quantification of ATP, which signals the presence of metabolically active cells. The luminescent signal was measured using the GLOMAX Luminometer system. Data were presented as proportional viability (%) by comparing the treated group with the untreated cells, the viability of which is assumed to be 100%.

**Tissue homogenization and fractionation**

Pieces of tissues obtained from liver, kidney, and brain of control and *Pistacia lentiscus* treated mice were rinsed with ice-cold PBS (pH 7.4) before homogenization in 10 mM phosphate buffer pH 7.4 containing 0.15M KCl, 0.1mM EDTA, 1mM DTT and 0.1mM phenylmethylsulfonylfluoride at 4°C. Postmitochondrial (PMS) fractions were prepared by centrifugation as described before [22].
Measurement of ROS and lipid peroxidation

ROS in different tissues of control and treated mice was measured using DCFDA as a fluorescent probe or by lucigenin based chemiluminescence methods as described before Raza et al 2004. NADPH-dependent membrane lipid peroxidation was measured as thiobarbituric acid reactive substance using malondialdehyde as a standard [22].

Measurement of GSH pool and metabolism

GSH levels and enzymes of GSH metabolism in the PMS fractions of control and treated mouse tissues were measured by standard procedures as described in previous publications [23, 24].

Measurement of CYP activities

CYP 2E1, CYP3A4, CYP1A1 and CYP1A2 activities in the tissues from control and treated mice tissues were measured using standard substrates, DMNA (for CYP 2E1), erythromycin (for CYP 3A4), 7-ethoxyresorufin (for CYP1A1) and 7-methoxyresorufin (for CYP1A2) and respectively as described previously [25] and [22].

SDS-PAGE and Western blot analysis

Proteins (50 µg) from control and Pistacia lentiscus treated tissue were separated on 12% SDS-PAGE and electrophoretically transferred onto nitrocellulose paper by Western blotting using the standard procedures previously described [22]. The immunoreacting protein bands were visualized after interacting with primary antibodies against CYP 2E1, CYP3A4, CYP1A1 and CYP1A2. Beta-actin expression in each tissue was used as a loading control.

Statistical analysis

Results were expressed as means ± S.E.M. of the number of experiments. The difference between experimental and control values were analyzed using the unpaired Student’s t-test. P<0.05 indicate a significant difference.

Results

Effect of Pistacia lentiscus oil on animal weight and hematological, kidney, and liver function tests

Five days oral treatment with Pistacia lentiscus oil 100 µl per mice doesn’t show any undesirable effect on body weight or increases in LDH concentration in the serum (Fig. 1A and 1B). In addition, there were no visible abnormalities at necropsy, or any other obvious signs of toxicity. Compared to the control group, no effect of Pistacia lentiscus oil on the white blood cell count (WBC), red blood cell count (RBC), hemoglobin concentration (HGB), hematocrit (HCT), platelet count, mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC) (Fig. 2A-H; p>0.05). Fig. 3 also shows the absence of statistically significant effects of Pistacia lentiscus oil on BUN, creatinine, ALT and AST activities in mice (Fig. 3A-D; p>0.05). These data suggest a good safety profile for potential human use of Pistacia lentiscus oil in short term therapy. All these experiments were repeated three times.

Effect of Pistacia lentiscus oil on gastrointestinal tract cell proliferation

Microscopic examination of control and Pistacia lentiscus treated gastrointestinal tissues (stomach, small intestine and colon) revealed similar structural features with intact lining epithelium suggesting no toxic effect for the Pistacia lentiscus oil on the structure of the gastrointestinal tract (Fig. 4A-D). Since the gastrointestinal epithelium is a highly dynamic tissue [26], it was used to test whether Pistacia lentiscus oil has any effect on cell proliferation. BrdU labeling studies revealed similar pattern of distribution of dividing cells in the three different regions examined in the gastrointestinal tract of both control and Pistacia lentiscus oil treated mice (Fig. 4A-D).
Effect of Pistacia lentiscus oil on cellular viability

To confirm in vitro the safety profile of Pistacia lentiscus oil on the mice gastrointestinal tract in vivo, we investigated the impact of Pistacia lentiscus oil on cellular viability (cell death and proliferation) of three gastrointestinal cells namely mouse gastric stem cells MGSC, human colorectal cancer cells HT29, and human hepatoma cells HepG2. As shown in Table 1, Pistacia lentiscus oil dilutions (10⁻⁶ - 10⁻³) doesn’t have any impact on the cellular viability of MGSC, HT29, and HepG2 cells over 24 and 48 hours. All together, these data confirm the safety oral use of Pistacia lentiscus oil on the gastrointestinal tract.
Effect of Pistacia lentiscus oil on ROS and LPO

There was no significant effect of Pistacia lentiscus oil on the ROS production in the liver and kidney. On the other hand brain from Pistacia lentiscus treated mice showed a mild (20%) increase in ROS production which was statistically significant (p<0.05). Similarly, there was no significant changes in the rate of membrane LPO in the tissues of Pistacia lentiscus treated mice (Table 2).

Effect of Pistacia lentiscus oil on GSH metabolism

GSH content was marginally (18%) reduced in the liver of Pistacia lentiscus treated animals while no appreciable changes were observed in the kidneys and brain. Similarly, GST activity in the liver of Pistacia lentiscus treated mice, with CDNB as a substrate was also inhibited (25%). On the other hand, no significant changes were observed in the kidney and brain of Pistacia lentiscus treated animals. No significant effect on GSH-Px and GSH-reductase activities in the tissues Pistacia lentiscus treated mice except GSH-Px in the liver (Table 2).

Effect of Pistacia lentiscus oil on CYP-dependent metabolism

A marked inhibition (42%) of CYP2E1 activity was observed in the liver of Pistacia lentiscus treated mice. However, this inhibition was not statistically significant (p>0.05). Similarly, CYP2E1 activities in the kidney and brain were not significantly affected. On the other hand, a statistically significant 40-80% decrease in the activities of CYP3A4, CYP1A1 and CYP1A2 was observed in the liver of Pistacia lentiscus treated mice (p<0.01). However, no significant alterations in the CYP3A4 and CYP1A1 were observed in the kidney and brain of treated animals. While CYP1A2 activity was significantly decreased in all the tissues of

*Effect of Pistacia lentiscus oil on ROS and LPO*

There was no significant effect of Pistacia lentiscus oil on the ROS production in the liver and kidney. On the other hand brain from Pistacia lentiscus treated mice showed a mild (20%) increase in ROS production which was statistically significant (p<0.05). Similarly, there was no significant changes in the rate of membrane LPO in the tissues of Pistacia lentiscus treated mice (Table 2).

*Effect of Pistacia lentiscus oil on GSH metabolism*

GSH content was marginally (18%) reduced in the liver of Pistacia lentiscus treated animals while no appreciable changes were observed in the kidneys and brain. Similarly, GST activity in the liver of Pistacia lentiscus treated mice, with CDNB as a substrate was also inhibited (25%). On the other hand, no significant changes were observed in the kidney and brain of Pistacia lentiscus treated animals. No significant effect on GSH-Px and GSH-reductase activities in the tissues Pistacia lentiscus treated mice except GSH-Px in the liver (Table 2).

*Effect of Pistacia lentiscus oil on CYP-dependent metabolism*

A marked inhibition (42%) of CYP2E1 activity was observed in the liver of Pistacia lentiscus treated mice. However, this inhibition was not statistically significant (p>0.05). Similarly, CYP2E1 activities in the kidney and brain were not significantly affected. On the other hand, a statistically significant 40-80% decrease in the activities of CYP3A4, CYP1A1 and CYP1A2 was observed in the liver of Pistacia lentiscus treated mice (p<0.01). However, no significant alterations in the CYP3A4 and CYP1A1 were observed in the kidney and brain of treated animals. While CYP1A2 activity was significantly decreased in all the tissues of
**Pistacia lentiscus** treated mice (Table 3; p<0.05). Western blot analysis has also confirmed the alteration in the expression of CYP2E1, CYP3A4, CYP1A1 and CYP1A2. The liver appears to be the main target for the reduced expression of key CYPs, which was in accordance with the alterations in the respective catalytic activities with their specific substrates (Fig. 5).

**Discussion**

**Pistacia lentiscus** is used as a seasoning in Mediterranean cuisine, in the production of natural chewing gum, in perfumery, in dentistry, and also for the relief of gastralgia and protection against peptic ulcer [13]. Based on the abovementioned information and since the most common of its therapeutic use has been for gastrointestinal disorders, we decided to treat the TO mice orally with 100 µl **Pistacia lentiscus** oil for 5 consecutive days in order to investigate whether it has any toxic effects in short term treatment. In general, a 70 kg man has a surface area 350 times higher than a 30 g mouse. In traditional medicine an adult man...
will be using 10 ml of *Pistacia lentiscus* once to twice a day for 3 to 5 days. Then, the 100 µl *Pistacia lentiscus* oil used in mice is a little higher than the 10 ml of *Pistacia lentiscus* used once to twice a day in traditional medicine.

A chronic toxicological study showed that dietary treatment with mastic gum for 13 weeks decreased body weights at the high dose, and also increased liver weights [18]. A more recent study demonstrates a promotion potential of mastic on the formation of pre-neoplastic lesions in the established rat liver medium-term carcinogenesis bioassay [27]. On the contrary, our dietary treatment with *Pistacia lentiscus* oil for 5 days shows an extremely

safe profile on animal weight, as well as on the most direct target toxicity organs blood, kidney and liver. Effectively, no increases in serum concentration of LDH was observed after treatment with *Pistacia lentiscus* oil which is in line with previously published report *in vitro* indicating no leakage of the cytosolic enzyme LDH into the extracellular space after treatment with *Pistacia lentiscus* oil [28]. No damage of the gastrointestinal mucosa or alteration in cell proliferation was observed which is in line with the capacity of *Pistacia lentiscus* oil to eradicate *Helicobacter pylori* and treat gastro-duodenal ulcer [14, 16]. These results have shown that the *Pistacia lentiscus* oil contents have little effects on the GSH-dependent redox metabolism in treated mice for this period and dose. However, it appears that at this dose and time point, *Pistacia lentiscus* oil treatment has inhibited the expression and the activities of CYP2E1, CYP3A4, CYP1A1 and CYP1A2. P450-isoenzymes, CYP 3A4, CYP 1A2 and CYP 2E1, are abundant in the mouse liver, and found to be the main target of *Pistacia lentiscus* oil treatment. The majority of the pharmacologically active compounds and xenobiotics have been reported to be metabolized, including in humans, by CYP 3A4, CYP 1A2 and CYP 2E1, and therefore the inhibition of these CYPs by *Pistacia lentiscus* oil might have implications in drug metabolizing ability of individuals taking the *Pistacia lentiscus* oil as a treatment along with other drugs. However, when used as monotherapy, *Pistacia lentiscus* oil is expected to be a safe drug as demonstrated cross this study. It is, however, not clear from this study whether any specific component of the *Pistacia lentiscus* oil or their metabolites is effective in targeting the CYP isoenzymes in different tissues. Differential effects of oil treatment on the expression and activities of various CYPs in different tissues might also be associated with the different degree of bioavailability and metabolism of the active components present in the *Pistacia lentiscus* oil. Further studies are needed to identify the active compound(s) which is selectively inhibiting the CYP isoenzymes in different tissues. Future studies are also planned to elucidate the mechanism of CYP inhibition at the mRNA/protein expression level. In addition, we also planned to study the kinetics of the inhibition of CYP activity by *Pistacia lentiscus* oil under *in vitro* and *in vivo* conditions.

Therefore, treatment or usage of this *Pistacia lentiscus* oil should be recommended with cautions as metabolism of drugs in general may be affected by inhibition of different P450s in tissues and especially in the liver which is the main target of drug metabolism. In addition, our results also demonstrate that GSH-dependent phase 2 conjugation reaction and detoxification of drugs, on the other hand may not be affected significantly by the *Pistacia lentiscus* oil treatment. There appears to be no significant effect on the oxidative stress as both, ROS production and membrane lipid peroxidation in the tissues were not appreciably and consistently affected by the *Pistacia lentiscus* oil treatment. Our results, especially

---

*Fig. 5.* 50 µg of proteins from control (C) and *Pistacia lentiscus* oil treated (T) tissues (liver, kidney and brain) were separated on 12% SDS-PAGE. The proteins were transferred to nitrocellulose membrane by Western blotting and immunoreactive bands were visualized by reacting with antibodies against CYP2E1, CYP3A4, CYP1A1 and CYP1A2. Beta-actin was used as a loading control. R.I values indicate relative intensity of the protein band (as determined by gel densitometer from Vilber Lormat, France) using expression of the proteins in the control tissues as 1.0. A typical blot from three repeated experiments is shown.
targeted effects on CYP activities are significant in determining the efficacy of prodrugs which require metabolic activation for their pharmacological effects. This study may also have implications on activation and inactivation of pro-carcinogen/carcinogens (polycyclic aromatic hydrocarbon “PAH”, benzo (a) pyrene “BP”, cigarette smoke, etc) in biological systems when treated with this edible oil. The anti-carcinogenic effect of *Pistacia lentiscus* oil may be associated with its inhibitory effect on carcinogen activation by CYP 1A1/1A2. On the contrary, it has been reported that Chios Mastic Gum has a potential on the formation of pre-neoplastic lesions in the established rat liver medium-term carcinogenesis bioassay [27].

**Conclusions**

*Pistacia lentiscus* oil treatment has inhibited specific CYP isoenzymes expression and catalytic activities as determined by using isoenzyme-specific substrates and antibodies. However, this effect on the key CYPs seems to be tissue- and isoenzyme-specific and further studies in progress will elucidate the mechanism of the inhibition of CYP activities in *Pistacia lentiscus* oil treated animals. *Pistacia lentiscus* oil treatment orally, however, does not seem to induce any acute tissue specific toxicity as shown by analyzing the stable markers and histochemistry of the target tissue. Also, the overall redox homeostasis and GSH-dependent detoxification mechanism in the tissues remained more or less unaltered after the *Pistacia lentiscus* oil treatment. *Pistacia lentiscus* oil can be safely used in monotherapy. However, due to its inhibitory effect on both the activities and the expression of various CYPs, careful attention is need when *Pistacia lentiscus* oil is intended to be combined with other drugs due to potential drug-drug interaction leading to toxicity. This study will help in safer use of *Pistacia lentiscus* oil for therapeutic purpose.
