Removing Singularities

Shmuel Elitzur, Amit Giveon, Eliezer Rabinovici

Racah Institute of Physics, The Hebrew University, Jerusalem, 91904, Israel

Big bang/crunch curvature singularities in exact CFT string backgrounds can be removed by turning on gauge fields. This is described within a family of $\frac{SL(2) \times SU(2) \times U(1)_x}{U(1) \times U(1)}$ quotient CFTs. Uncharged incoming wavefunctions from the “whiskers” of the extended universe can be fully reflected if and only if a big bang/crunch curvature singularity, from which they are scattered, exists. Extended BTZ-like singularities remain as long as $U(1)_x$ is compact.
1. Introduction

Studies of the propagation of strings in time-dependent backgrounds have highlighted several basic issues. One is related to the possibility that extended objects such as strings may propagate beyond space-like singularities. Another concerns the manner one may embed a compact cosmology in an allowed perturbative string background. A third related issue involves the appropriate boundary conditions to be imposed in the presence of such singularities. A way to evaluate an entropy in string cosmology was addressed as well. These difficult issues were investigated in exact perturbative CFT backgrounds. The first issue was addressed in two types of CFT backgrounds. One set of string backgrounds consists of orbifolds of $\mathbb{R}^{1,d-1}$\[1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18\]. Such space-times are flat away from the singularities. In the second class of CFT backgrounds [19,20,21], gauged WZW models [22,23,24,25,26,27], there are two types of singularities. The first is also of an orbifold nature, in these cases either an $\mathbb{R}^{1,1}$/Boost or an extended BTZ-like singularity [33,34,35,36,37], whose global structure is that of AdS. The second is a Ricci curvature singularity where also the dilaton diverges. In what follows we focus on the quotient CFT background investigated in [25].

The attitude taken in these studies was to assume the validity of string perturbation theory, and to compute physical quantities by standard worldsheet techniques. Several intriguing results emerged [25]. Strings were found to propagate through these singularities. Each expanding universe is connected to a pre collapsing universe at their corresponding big bang/crunch singularities – a pre big bang scenario (for a review, see [38]). Moreover, the compact cosmological models were found to be accompanied by static “whiskers,” which have a non-compact direction with a space-like linear dilaton. In the whiskers an S-matrix setup is possible. Boundary conditions can be set in a weak coupling asymptotic regime, determining the boundary conditions at the singularities. The entropy was found to be significantly reduced (relative to other theories with global AdS structure or with an asymptotic space-like linear dilaton). The whiskers also include closed time-like curves and time-like domain wall singularities.

In this work we present a larger class of models in which compact cosmologies are once again embedded in a non-compact space-time which includes whiskers. In this family of models one can gradually separate the curvature singularities from the BTZ-like singularities. The big bang/crunch curvature singularity can be removed by pushing the
domain wall connected to it towards the boundary of the whisker, leaving behind an extended BTZ-like singularity at the times when a compact universe meets a whisker. The nature of the singularity may play a role in the important question regarding the validity of perturbation theory. A general argument is that as the universe collapses, a large amount of energy will eventually be concentrated near the space-like singularity, causing a large back reaction on the structure of the singularity [39, 14, 17]. As a consequence, this may affect the validity of perturbation theory [13, 17]. The extended BTZ-like singularities which appear in our family of quotient CFTs have an AdS structure which might affect the strength of the back reaction, and as a consequence, the question regarding the validity of perturbation theory.

The time-dependent string background studied in [25] is based on the quotient CFT [21]. As mentioned, it consists of a sequence of closed, expanding and recollapsing universes, each connected at its big bang and big crunch singularities to the whiskers [25]. Observables in this string background are of two kinds. Wavefunctions localized near the closed universes correspond to vertex operators in the quotient CFT which are exponentially supported at the boundary of the whiskers. On the other hand, scattering states correspond to delta-function normalizable vertex operators. From the latter, one can construct linear combinations which describe incoming waves prepared in a certain whisker and scattered from the big bang/crunch singularities. Generically, these waves are partially reflected from the singularity. However, it was found that one can always prepare scattering waves which are fully reflected from the singularity. These are regular combinations of physical wavefunctions each of which develops a logarithmic singularity at the corresponding big bang/crunch.

In this note, we show that by turning on an Abelian gauge field one can remove the curvature singularities in the time-dependent background of [21, 25]. Removing such singularities was done previously by \(O(d, d, \mathbb{R})\) rotations of \(\frac{SL(2, \mathbb{R}) \times SU(2)}{U(1) \times U(1)} \times \mathbb{R}\) in [23, 24] (for a review, see [10]). By turning on gauge fields one can remove the big bang and/or the big crunch curvature singularities. We show that by gradually turning on a gauge field one can “push” a big bang/crunch singularity and the domain wall singularity to which it is connected in the whisker (see [25] for details) towards the boundary of space-time. For particular values of the gauge field the background has no curvature singularity. On the other hand, extended BTZ-like orbifold singularities remain, unless the extra fifth dimension \(U(1) \times \mathbb{R}\) is non-compact.
Here we study the cosmology of \([21]\) in the presence of a gauge field by considering a three-parameter subfamily of the \(\frac{SL(2, \mathbb{R}) \times SU(2) \times U(1)}{U(1) \times U(1)}\) quotient CFTs. This allows us to consider physical vertex operators in such backgrounds. We find that fully reflected uncharged wavefunctions exist if and only if there is a big bang or big crunch singularity from which they are scattered.

In section 2, we describe the geometry of the \(\frac{SL(2, \mathbb{R}) \times SU(2) \times U(1)}{U(1) \times U(1)}\) sigma-model and the wavefunctions in this CFT background. In section 3, we discuss the singularities, their removal, and the corresponding behavior of the wavefunctions. Our main results are summarized in section 4. In appendix A, we present the relation between singularities in quotient CFT backgrounds and fixed points in the underlying sigma-model under a subgroup of the gauged isometry group.

2. \([SL(2, \mathbb{R}) \times SU(2) \times U(1)]/U(1)^2\)

2.1. Geometry

We construct a 5-dimensional time-dependent background by gauging the WZW model of the 7-dimensional \(SL(2, \mathbb{R}) \times SU(2) \times U(1)\) group manifold by a non-compact space-like \(U(1)\) subgroup. Let \((g, g', x)\) be a point on the product group manifold and let \(k\) and \(k'\) be the levels of \(SL(2, \mathbb{R})\) and \(SU(2)\) respectively. Here \(g \in SL(2, \mathbb{R})\), \(g' \in SU(2)\) and \(x\) denotes a point on the unit circle. The \(U(1)^2\) gauge group acts as

\[
(g, g', x_L, x_R) \rightarrow (e^{\rho \sigma_3/\sqrt{k}} g e^{\tau \sigma_3/\sqrt{k'}}, e^{i \rho' \sigma_3/\sqrt{k'}} g' e^{i \tau' \sigma_3/\sqrt{k'}}, x_L + \rho'', x_R + \tau'')
\]  

(2.1)

Since we gauge only \(U(1)^2\) out of the three \(U(1)\) right-handed generators in (2.1), the three parameters \(\tau, \tau'\) and \(\tau''\) are not independent but rather are constrained by

\[
\mathbf{v} \cdot \mathbf{\tau} \equiv v_1 \tau + v_2 \tau' + v_3 \tau'' = 0
\]  

(2.2)

where \(\mathbf{v}\) is some real 3-vector. The left-handed parameters \(\rho, \rho'\) and \(\rho''\) in (2.1) depend linearly on the right-handed \(\tau\) parameters. For an anomaly free gauging this dependence has to take the form

\[
\mathbf{\rho} = R \mathbf{\tau}
\]  

(2.3)

where \(\mathbf{\rho}\) is a 3-vector with \(\rho, \rho'\) and \(\rho''\) as components, similarly for \(\mathbf{\tau}\), and \(R\) is a \(3 \times 3\) orthogonal matrix. Apart from \(k, k'\) and the radius of the circle parametrized by \(x\), our
model depends then on 5 parameters, three of them fixing the matrix $R$ in (2.3), and two more fixing the vector $v$, which is defined by (2.2) only up to a multiplication by a scalar.

To perform the gauging (2.1) one introduces dynamical fields $\hat{\rho}, \hat{\tau}$ corresponding to the parameters $\rho, \tau$ subject to the constraints

$$\hat{\tau} \cdot v = \hat{\rho} \cdot Rv = 0 \quad (2.4)$$

The gauged action is then defined by

$$S = S[e^{i\hat{\rho}/\sqrt{k}}g e^{i\hat{\tau}/\sqrt{k}}] + S'[e^{i\hat{\rho}'/\sqrt{k'}}g' e^{i\hat{\tau}'/\sqrt{k'}}] + S''[x + \hat{\rho}' + \hat{\tau}']$$

$$- \frac{1}{2\pi} \int d^2z (\partial \hat{\rho} - R \partial \hat{\tau})^T (\bar{\partial} \hat{\rho} - R \bar{\partial} \hat{\tau}) \quad (2.5)$$

$S[g]$ is the WZW action of $g \in SL(2)$,

$$S[g] = \frac{k}{4\pi} \int_\Sigma Tr(g^{-1} \partial g g^{-1} \bar{\partial} g) - \frac{1}{3} \int_B Tr(g^{-1} dg)^3$$

where $\Sigma$ is the string’s worldsheet and $B$ a 3-submanifold of the group $SL(2)$ bounded by the image of $\Sigma$. $S'[g']$ is similarly defined for the group $SU(2)$,

$$S'[g'] = -\frac{k'}{4\pi} \int_\Sigma Tr(g'^{-1} \partial g' g'^{-1} \bar{\partial} g') - \frac{1}{3} \int_B Tr(g'^{-1} dg')^3 \quad (2.7)$$

Finally

$$S''[x] = \frac{1}{2\pi} \int_\Sigma \partial x \bar{\partial} x \quad (2.8)$$

Apart from the constraints (2.4), $\hat{\rho}$ and $\hat{\tau}$ are independent fields. The action (2.5) is invariant under the gauge transformation (2.1) for the fields $g, g'$ and $x$ together with the transformation

$$\hat{\rho} \rightarrow \hat{\rho} - \rho$$

$$\hat{\tau} \rightarrow \hat{\tau} - \tau \quad (2.9)$$

provided that the parameters $\rho$ and $\tau$ satisfy the relation (2.3). Using the Polyakov-Wiegmann identity one sees that the action (2.5) depends on $\hat{\rho}$ and $\hat{\tau}$ only through the quantities

$$A = \partial \hat{\tau}$$

$$\bar{A} = \bar{\partial} \hat{\rho} \quad (2.10)$$

The gauged action has then the form

$$S = S[g] + S'[g'] + S''[x] + \frac{1}{2\pi} \int d^2z [\bar{J}^T A + \bar{\lambda} v^T A + \bar{A}^T J + \lambda \bar{A}^T R \bar{v} + 2 \bar{A}^T M A] \quad (2.11)$$
Here, $A^T$ is the row vector $(A, A', A'')$ defined in (2.10) consisting of the holomorphic components of the gauge fields of $SL(2), SU(2)$ and $U(1)$, respectively, with a similar definition for $\bar{A}$. $J^T$ is the row vector of the currents,

$$
J^T = (\sqrt{k}Tr[g^{-1}\sigma_3], -i\sqrt{k'}Tr[g'^{-1}\sigma_3], 2\partial x) \quad (2.12)
$$

Similarly, $\bar{J}^T$ is

$$
\bar{J}^T = (\sqrt{k}Tr[\bar{g}\sigma_3], -i\sqrt{k'}Tr[\bar{g}'\sigma_3], 2\bar{\partial} x) \quad (2.13)
$$

The $3 \times 3$ matrix $M$ in (2.11) is of the form,

$$
M = \begin{pmatrix}
\frac{1}{2}Tr[g^{-1}\sigma_3g\sigma_3] & 0 & 0 \\
0 & \frac{1}{2}Tr[g'^{-1}\sigma_3g'\sigma_3] & 0 \\
0 & 0 & 1
\end{pmatrix} + R \quad (2.14)
$$

$\lambda$ and $\bar{\lambda}$ are Lagrange multipliers enforcing the constraint corresponding to (2.4) on $A$ and $\bar{A}$.

Since (2.11) is invariant under the gauge transformation (2.1) and (2.9), integrating out the fields $A, \bar{A}$ leaves an action depending on $g, g', x$, invariant under (2.1). Fixing this gauge invariance results in a 5-dimensional sigma-model action containing the geometrical information of the resulting space-time.

Parametrize $g$ as

$$
g = e^{\alpha\sigma_3 g(\theta_1)} e^{\beta\sigma_3} \quad (2.15)
$$

This parametrization is valid for any matrix $g$ with non-zero elements. The definition of the factor $g(\theta_1)$ depends on the region where $g$ is in the $SL(2)$ group manifold [1], [25]. Defining

$$
W = Tr(\sigma_3 g \sigma_3^{-1}) \quad (2.16)
$$

g(\theta_1)$ stands for $e^{i\theta_1\sigma_2}$ in regions of $SL(2)$ for which $W$ satisfies $|W| \leq 2$. The points of $SL(2)$ for which $W > 2$ are divided into 4 regions. There the factor $g(\theta_2)$ represents $\pm e^{i\theta_2\sigma_1}$. For the 4 regions where $W < -2$, $g(\theta_3) = \pm i \sigma_2 e^{\pm \theta_3 \sigma_1}$. At the point $\theta_1 = 0$, $W = 2$. Here two of the regions parametrized by $\theta_2$ meet the region parametrized by $\theta_1$. Similarly, at $\theta_1 = \pi$ the other two regions parametrized by $\theta_2$ meet the region parametrized by $\theta_1$. At $\theta_1 = \frac{\pi}{2}$ ($W = -2$) two regions parametrized by $\theta_3$ meet the $\theta_1$ region and at $\theta_1 = \frac{3\pi}{2}$ the other two $\theta_3$ regions meet the $\theta_1$ region. The range of $\theta_{2,3}$ is $0 \leq \theta_{2,3} < \infty$. For the group $SL(2)$, $\theta_1$ satisfies $0 \leq \theta_1 \leq 2\pi$. For the infinite cover of $SL(2)$, $\theta_1$ satisfies $-\infty < \theta_1 < \infty$. 

5
Parametrize $g'$ by the Euler angles

$$g' = e^{i\alpha' \sigma_3} e^{i\theta' \sigma_2} e^{i\beta' \sigma_3}$$

(2.17)

with $0 \leq \alpha' < 2\pi$, $0 \leq \theta' \leq \frac{\pi}{2}$, $0 \leq \beta' < \pi$. In these terms the currents in (2.12) and (2.13), in regions where $|W| \leq 2$, take the form

$$J^T = \left(2\sqrt{k} (\partial \alpha + \cos(2\theta_1) \partial \beta), 2\sqrt{k'} (\partial \alpha' + \cos(2\theta') \partial \beta'), 2\partial x \right)$$

(2.18)

$$\bar{J}^T = \left(2\sqrt{k} (\partial \beta + \cos(2\theta_1) \partial \alpha), 2\sqrt{k'} (\partial \beta' + \cos(2\theta') \partial \alpha'), 2\partial x \right)$$

(2.19)

In the regions where $W > 2$, $\theta_1$ in (2.18), (2.19) should be replaced by $i\theta_2$. In the regions with $W < -2$, substitute $i\theta_3$ for $\theta_1 - \frac{\pi}{2}$.

Fix the $U(1) \times U(1)$ gauge by the condition,

$$\alpha = \beta = 0$$

(2.20)

which is possible wherever the parametrization (2.13) is valid. The resulting 5-dimensional manifold is parametrized by $(\theta, \theta', \alpha', \beta', x)$. Generically, at points where the parametrization (2.13) is valid the manifold looks like a family of $SU(2) \times S^1$ manifolds parametrized by the continuous parameter $\theta_i$ in each of the regions of $SL(2)$ described above. At points corresponding to $g \epsilon SL(2)$ with vanishing elements, including the points $\theta_1 = 0, \frac{\pi}{2}, \pi, \frac{3\pi}{2}$ where various regions meet, the gauge fixing (2.20) is not complete and has to be supplemented by a gauge condition on the $SU(2)$ or $U(1)$ part. Above these points the $SU(2) \times S^1$ manifold will be twisted by some extra identification.

The fixing (2.20) sets the first components of $J$ and $\bar{J}$ in (2.18) and (2.19) to zero. Substituting (2.20) into (2.11) then integrating out $A, \bar{A}, \lambda$ and $\bar{\lambda}$ one gets the sigma-model action for the 5-dimensional target space as,

$$S = \int d^2z \left\{ -\frac{k}{2\pi} \partial \theta_1 \bar{\partial} \theta_1 + \frac{k'}{2\pi} \left( \partial \theta' \bar{\partial} \theta' + \partial \alpha' \bar{\partial} \alpha' + \partial \beta' \bar{\partial} \beta' + 2\cos(2\theta') \partial \alpha' \bar{\partial} \beta' \right) + \frac{1}{2\pi} \partial \bar{\partial} x \partial \bar{\partial} x 
- \frac{k'}{\pi} \left[(M^{-1})_{2,2} - \frac{1}{v_m (M^{-1}R)_{m,n} v_n} (M^{-1}R)_{2,k} v_k v_l M_{l,2}^{-1} \right] \left( \partial \alpha' + \cos(2\theta') \partial \beta' \right) \left( \bar{\partial} \beta' + \cos(2\theta') \bar{\partial} \alpha' \right) 
- \sqrt{k'} \frac{k}{\pi} \left[(M^{-1})_{2,3} - \frac{1}{v_m (M^{-1}R)_{m,n} v_n} (M^{-1}R)_{2,k} v_k v_l M_{l,3}^{-1} \right] \partial x \left( \bar{\partial} \beta' + \cos(2\theta') \bar{\partial} \alpha' \right) 
- \sqrt{k'} \frac{k}{\pi} \left[(M^{-1})_{3,2} - \frac{1}{v_m (M^{-1}R)_{m,n} v_n} (M^{-1}R)_{3,k} v_k v_l M_{l,2}^{-1} \right] \left( \partial \alpha' + \cos(2\theta') \partial \beta' \right) \bar{\partial} x 
- \frac{1}{\pi} \left[(M^{-1})_{3,3} - \frac{1}{v_m (M^{-1}R)_{m,n} v_n} (M^{-1}R)_{3,k} v_k v_l M_{l,3}^{-1} \right] \partial \bar{\partial} x \right\}$$

(2.21)
The dilaton field $\Phi$, defined such that the string coupling $g_s$ equals $e^\Phi$, becomes in this geometry
\[
\Phi = \Phi_0 - \frac{1}{2} \left[ \log(\det M) + \log(v_m(M^{-1}R)_{m,n}v_n) \right]
\]  \hfill (2.22)
In regions where $W > 2$, $\theta_1$ in (2.21) should be replaced by $i\theta_2$. Similarly, in regions where $W < -2$, $\pi/2 - \theta_1$ should be replaced by $i\theta_3$.

We focus on geometries which are essentially 4-dimensional, namely, those for which the length of the extra circle parametrized by $x$ is constant. This will emerge if the parameters of the model are chosen such that the last term in (2.21), proportional to $\partial x \bar{\partial} x$, vanishes. This happens when we chose the vector $\nu$ of the form
\[
\nu^T = (0, 0, 1)
\]  \hfill (2.23)
This means, by (2.2), that no gauging is applied to $x_R$. Note that such a gauging can also be applied to heterotic backgrounds where the $U(1)$ symmetry may exist only from the left with no right-handed part from the start. Note also that with the choice (2.23), in addition to the term proportional to $\partial x \bar{\partial} x$, also the term proportional to $(\partial \alpha' + \cos(2\theta') \partial \beta') \bar{\partial} x$ vanishes. The condition (2.23) selects a 3-parameter family of models parametrized by $R$.

The dilaton field of (2.22) for this case is
\[
\Phi = \Phi_0 - \frac{1}{2} \log \left[ 1 + R_{3,3} \cos(2\theta_1) \cos(2\theta') + R_{1,1} \cos(2\theta_1) + R_{2,2} \cos(2\theta') \right]
\]  \hfill (2.24)
The action (2.21) becomes
\[
S = \int d^2z \left\{ -\frac{k}{2\pi} \partial \theta_1 \bar{\partial} \theta_1 + \frac{k'}{2\pi} \left( \partial \theta' \bar{\partial} \theta' + \partial \alpha' \bar{\partial} \alpha' + \partial \beta' \bar{\partial} \beta' + 2\cos(2\theta') \partial \alpha' \bar{\partial} \beta' \right) + \frac{1}{2\pi} \partial x \bar{\partial} x 
\right. 
- \frac{k'}{\pi} \left[ \frac{1}{(\cos(2\theta_1) + \cos(2\theta'))(R_{1,1} + R_{2,2}) + (1 + \cos(2\theta_1) \cos(2\theta'))(1 + R_{3,3})} \right. 
\times \left[ R_{1,1} + R_{2,2} + \cos(2\theta_1)(1 + R_{3,3}) - e^{2(\Phi - \Phi_0)}(\cos(2\theta_1)R_{2,3} - R_{3,2})(R_{2,3} - \cos(2\theta_1)R_{3,2}) \right] 
\times (\partial \alpha' + \cos(2\theta') \partial \beta')(\bar{\partial} \beta' + \cos(2\theta') \bar{\partial} \alpha') 
\left. \right. 
\left. \right. 
- \frac{\sqrt{k'}}{\pi} e^{2(\Phi - \Phi_0)}(R_{3,2} - \cos(2\theta_1)R_{2,3}) \partial x(\bar{\partial} \beta' + \cos(2\theta') \bar{\partial} \alpha') \right\}
\]  \hfill (2.25)
where $\Phi$ is the dilaton field defined in (2.24).

Expressing the matrix $R$ in terms of the Euler coordinates as
\[
R = e^{\chi I_3} e^{\psi I_2} e^{\phi I_3} = \begin{pmatrix} \cos \chi & \sin \chi & 0 \\ -\sin \chi & \cos \chi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \cos \psi & 0 & -\sin \psi \\ 0 & 1 & 0 \\ \sin \psi & 0 & \cos \psi \end{pmatrix} \begin{pmatrix} \cos \phi & \sin \phi & 0 \\ -\sin \phi & \cos \phi & 0 \\ 0 & 0 & 1 \end{pmatrix}
\]  \hfill (2.26)
where \((I_i)_{j,k} = \epsilon_{ijk}\), we have for the dilaton field

\[
\Phi = \Phi_0 - \frac{1}{2} \log \left[ 1 + \cos\psi \cos(2\theta_1) \cos(2\theta') + \cos\psi \cos\chi \cos\phi - \sin\chi \sin\phi \cos(2\theta_1) \right.
\]

\[
- \left. \left( \cos\psi \sin\chi \sin\phi - \cos\chi \cos\phi \right) \cos(2\theta') \right] 
\]

\[
= \Phi'_0 - \frac{1}{2} \log(\cos^2 \theta_1 \sin^2 \theta')
\]

\[
+ \ a^2 \cos^2 \theta_1 \cos^2 \theta' + b^2 \sin^2 \theta_1 \cos^2 \theta' + c^2 \sin^2 \theta_1 \sin^2 \theta')
\]

where \(\Phi'_0 = \Phi_0 - \frac{1}{2} \log [(1 - \cos\psi)(1 - \cos(\chi - \phi))]\) and

\[
a^2 = \frac{(1 + \cos\psi)(1 + \cos(\chi + \phi))}{(1 - \cos(\chi - \phi))} \tag{2.28}
\]

\[
b^2 = \frac{1 + \cos(\chi - \phi)}{1 - \cos(\chi - \phi)} \tag{2.29}
\]

\[
c^2 = \frac{(1 + \cos\psi)(1 - \cos(\chi + \phi))}{(1 - \cos(\chi - \phi))} \tag{2.30}
\]

The action in this parametrization is

\[
S = \int d^2 z \left\{ - \frac{k}{2\pi} \partial \theta_1 \bar{\partial} \theta_1 + \frac{k'}{2\pi} \left( \partial \theta' \bar{\partial} \theta' + \partial \alpha' \bar{\partial} \alpha' + \partial \beta' \bar{\partial} \beta' + 2 \cos(2\theta') \partial \alpha' \bar{\partial} \beta' \right) + \frac{1}{2\pi} \partial x \bar{\partial} x 
\]

\[
- \frac{k'}{\pi} \left[ (1 + \cos\psi) \left[ \cos(2\theta_1) \cos(2\theta') + 1 + \cos(2\theta_1) + \cos(2\theta') \right] \cos(\chi + \phi) \right.
\]

\[
\times \left. \left[ (1 + \cos\psi) - \cos(2\theta_1) \cos(\chi + \phi) \right] - e^{2(\Phi - \Phi_0)} \sin^2 \psi \left( \sin\phi - \cos(2\theta_1) \sin\chi \right) \left( \cos(2\theta_1) \sin\phi - \sin\chi \right) \right]
\]

\[
\times \left( \partial \alpha' + \cos(2\theta') \partial \beta' \right) \left( \bar{\partial} \beta' + \cos(2\theta') \bar{\partial} \alpha' \right)
\]

\[
- \frac{\sqrt{k'}}{\pi} e^{2(\Phi - \Phi_0)} \sin^2 \psi \left( \sin\phi - \cos(2\theta_1) \sin\chi \right) \partial x \left( \bar{\partial} \beta' + \cos(2\theta') \bar{\partial} \alpha' \right) \right\} \tag{2.31}
\]

The coordinates \(\alpha'\) and \(\beta'\) as \(SU(2)\) Euler angles are compact. \(\alpha' + \beta'\) and \(\alpha' - \beta'\) are defined modulo \(2\pi\). In regions for which \(W > 2\) replace \(\theta_1\) by \(i\theta_2\). For \(W < -2\) replace \(\pi/2 - \theta_1\) by \(i\theta_3\).

The model of ref. \[21\] is a special subset of the present family of models, corresponding to \(\psi = \pi\) \((a = c = 0)\). The parameter \(\alpha\) there is related to the present parametrization as \(\alpha = \chi - \phi - \pi/2\) \((b^2 = 1 - \sin \alpha/1 + \sin \alpha)\).

\[1\] This is the same dilaton as in \[23\] (for a review, see \[40\]).
For large $k,k'$ and for small radius of the circle parametrized by $x$, the action (2.31) describes a 4-dimensional space-time parametrized by $(\theta, \theta', \alpha', \beta')$. The 5-dimensional metric and antisymmetric tensor read from (2.31), produce a corresponding 4-dimensional structure via the Kaluza-Klein mechanism. The term proportional to $\partial x(\bar{\partial} \beta' + \cos(2\theta')\bar{\partial} \alpha')$ gives rise in 4 dimensions to a $U(1)$ gauge field which couples to the momentum as well as to the winding along the $x$ circle. Equation (2.31) describes only the patch corresponding to $|W| \leq 2$, the full model contains also the other patches which have the same metric with $\theta_1$ replaced by $i\theta_2$ or $\pi/2 - i\theta_3$.

When $a = c = 0$ the gauge field vanishes, and the 4-dimensional background takes the form (for $k = k'$ in regions with $|W| \leq 2$):

$$\frac{1}{k}ds^2 = -d\theta_1^2 + d\theta'^2 + \frac{b^2 \cot^2 \theta'}{b^2 + \tan^2 \theta_1 \cot^2 \theta'} d\lambda_+^2 + \frac{\tan^2 \theta_1}{b^2 + \tan^2 \theta_1 \cot^2 \theta'} d\lambda_-^2$$

$$B_{\lambda_+\lambda_-} = \frac{kb^2}{b^2 + \tan^2 \theta_1 \cot^2 \theta'}$$

$$\Phi = \Phi_0 - \frac{1}{2} \log(\cos^2 \theta_1 \sin^2 \theta' + b^2 \sin^2 \theta_1 \cos^2 \theta')$$

where $\alpha' \pm \beta' \equiv \lambda_\pm \in [0, 2\pi)$ and, again, in regions for which $|W| > 2$ make the appropriate replacement for $\theta_1$. This is the one parameter family of 4-dimensional time-dependent backgrounds with two Abelian isometries discussed in [21,23]. It describes a series of closed, inhomogeneous expanding and recollapsing universes in $1 + 3$ dimensions. At the time $\theta_1 = 0$ (modulo $\pi$) there is a big bang singularity, while at $\theta_1 = \pi/2$ (modulo $\pi$) there is a big crunch singularity.

More precisely, at the time $\theta_1 = 0$ and on the surface $\theta' = 0$ there is a curvature singularity and the dilaton goes to infinity. On the other hand, for generic $\theta'$ there is an orbifold singularity, and the dilaton is finite. The orbifold singularity is a BTZ-like [33,34], namely, an orbifold of $SL(2, \mathbb{R})$ where we identify $g \simeq e^{i\sigma_3} ge^{-i\sigma_3}$, $g \in SL(2, \mathbb{R})$. Similarly, at the time $\theta_1 = \pi/2$ there is a BTZ-like singularity of the axial type $g \simeq e^{i\sigma_3} ge^{i\sigma_3}$, except on the surface $\theta' = \pi/2$ where there is a curvature singularity and the dilaton blows up.

These universes are connected to non-compact static “whiskers” [25] at the big bang/crunch singularities. The geometry of the whiskers with $W > 2$, attached at $\theta_1 = 0$,
is described by the metric (2.32) with $i\theta_2$ substituted for $\theta_1$. For any value of $\theta_1, \lambda_+, \lambda_-$ this geometry is singular for $\theta' \in [0, \frac{\pi}{2}]$ satisfying

$$\cot\theta' = \frac{b}{\tanh\theta_2}$$

(2.35)

The whisker is static and contains a singular “domain wall,” starting at the big bang singularity at $\theta_2 = 0$ extending to infinity where $\theta_2$ tends to $\infty$. Crossing this wall in the whisker, the role of time is exchanged between $\lambda_+$ and $\lambda_-$. Similarly, the whiskers with $W < -2$ are described by the geometry (2.32) with $\pi^2 - i\theta_3$ substituted for $\theta_1$. Again, there is a singular domain wall extending from the big crunch point at $\theta_1 = \frac{\pi}{2}$ which is the same point as $\theta_3 = 0$, towards infinity of $\theta_3$, which is described by the equation

$$\cot\theta' = \frac{b}{\coth\theta_3}$$

(2.36)

Non-zero parameters $a$ and $c$ (2.28), (2.30) correspond to turning on two components of an Abelian gauge field in the universe (2.32) – (2.34). Generically, these remove the big bang/crunch curvature singularities 23 24, as we shall discuss in section 3. Such backgrounds can be described by a 3-parameter sub-family of $O(2,3,\mathbb{R})$ rotations of the direct product of a two-dimensional black-hole $(SL(2,\mathbb{R})/U(1))$ with a parafermion sigma-model $(SU(2)/U(1))$ and a circle $(U(1))$ 23 24 (for a review, see 40).

2.2. Wavefunctions

The realization of the model as a quotient of a group manifold enables one to express vertex operators in terms of those of the ungauged WZW model 23. A typical vertex operator on $SL(2,\mathbb{R}) \times SU(2) \times U(1)$ which is unexcited in the $g, g'$ directions but may wind around the $x$ circle is of the form

$$V^{j,j',q;m,\bar{m},\bar{q}} = K_{j,m,\bar{m}}^j(m,\bar{m},\bar{q})e^{i(qxL + \bar{q}xR)}$$

(2.37)

Here $K_{j,m,\bar{m}}^j(g)$ is the matrix element of $g \in SL(2,\mathbb{R})$ in the representation with the value $-j(j + 1)$ for the Casimir operator, between states with eigenvalues $m$ and $\bar{m}$ for the infinitesimal generator corresponding to $\frac{1}{2}\sigma_3$. $D_{j,m',\bar{m}',g'}$ is similarly defined for $SU(2)$.

3 A representation from the continuous series of the infinite cover of $SL(2,\mathbb{R})$ is not completely determined by the value of $j$, an additional phase is required to specify it. Also for these representations to each value of $m$ corresponds a 2-dimensional subspace; another $Z_2$ variable is required to fix a state. In that case $K_{j,m,\bar{m}}^j(g)$ means to depend also on those extra variables (see 25 for details).
Applying the gauge transformation \( (2.1) \) to \((g, g', x)\) the operator \( V^{j,j'}_{m,m',q,\bar{m},\bar{m}',\bar{q}} \) gets multiplied by
\[
\exp \left[ i \left( \frac{m}{\sqrt{k}} \rho + \frac{m'}{\sqrt{k'}} \rho' + q \rho'' + \frac{\bar{m}}{\sqrt{k}} \tau + \frac{\bar{m}'}{\sqrt{k'}} \tau' + \bar{q} \tau'' \right) \right] \tag{2.38}
\]
On the coset, only those vertex operators for which this phase equals to 1 are allowed. Taking \( (2.3) \) into account we get a constraint on the allowed charges for a vertex operator. In matrix notation this reads
\[
\left( \frac{m}{\sqrt{k}}, \frac{m'}{\sqrt{k'}}, q \right) R + \left( \frac{\bar{m}}{\sqrt{k}}, \frac{\bar{m}'}{\sqrt{k'}}, \bar{q} \right) = 0 \tag{2.39}
\]
Here \( m', \bar{m}' \) are quantized to be half integral and \( q, \bar{q} \) are quantized on the Narain lattice \( \Gamma^{1,1} \).

3. Removing Singularities

3.1. Geometry

As mentioned in section 2, when the gauge field vanishes \((a = c = 0)\) the background \((2.27) - (2.31)\) describes a 4-dimensional closed universe \((2.32) - (2.34)\). This universe is singular at \( \theta_1 = \theta' = 0 \) (a big bang singularity) and at \( \theta_1 = \theta' = \frac{\pi}{2} \) (a big crunch singularity). These singularities can be seen, for instance, by inspecting the behavior of the dilaton \((2.27)\) when \( a = c = 0 \). Their origin is the presence of points on the group manifold which are fixed under a continuous subgroup of the \( U(1)^2 \) gauge group (see appendix A). Singular domain walls, extending into the whiskers, are attached to these big bang singularities. The domain walls emerge where the 2-dimensional gauged orbit becomes null \([25]\) (see appendix A). Turning on the gauge field generically removes the big bang/crunch singularities and pushes the domain walls into the whiskers. Next we discuss such singularities by inspecting the dilaton, and describe their relations with fixed points under subgroups of the gauged \( U(1)^2 \).

The dilaton field \((2.27)\) is generically regular throughout the region \(|W| \leq 2\). It develops singularities at some special points on the boundary of this region, only for some two-dimensional subsets of the three-dimensional parameter space \( R \). At the point \((\theta_1, \theta') = (0, 0)\) there is a singularity in \((2.27)\) for matrices \( R \) with \( \chi + \phi = \pi \) \((a = 0)\). At the point \((\theta_1, \theta') = \left( \frac{\pi}{2}, \frac{\pi}{2} \right)\) there is a singularity for \( \chi + \phi = 0 \) \((c = 0)\). At the point \((\theta_1, \theta') = (0, \frac{\pi}{2})\) singularity appears when \( \chi - \phi = 0 \) \((a, b, c \to \infty)\). Finally, at \((\theta_1, \theta') = (\frac{\pi}{2}, 0)\) the subset of models with \( \chi - \phi = \pi \) \((b = 0)\) form a singularity.
These singularities correspond to the presence of points on the original group manifold which are fixed under some continuous subgroup of the $U(1)^2$ gauge group. Thus the point $(\theta_1, \theta') = (0, 0)$ corresponds to $g(\theta) = g'(\theta') = 1$. This point is invariant under the subgroup of the gauge transformations (2.1) for which $\rho = -\tau, \rho' = -\tau'$ and $\rho'' = 0$. This is consistent with the condition (2.3) only for matrices $R$ for which there exists a vector of the form $(\rho, \rho', 0)$ which is rotated by $R$ into $(-\rho, -\rho', 0)$. This implies that this vector is the axis of rotation for the matrix $e^{\pi I_3 R}$. For a matrix of the form $e^{\chi I_3} e^{\psi I_2} e^{\phi I_3}$ the condition that the axis of rotation lies in the $(1, 2)$ plane is $\chi + \phi = 0$. Hence a singularity at the point $\theta_1 = \theta' = 0$ develops only for $R$ with $\chi + \phi = \pi$. For the same reason the point $(\theta_1, \theta') = (\pi, \pi)$, corresponding to $g(\theta) = g'(\theta') = i\sigma_2$ which is fixed by transformations with $\rho = \tau, \rho' = \tau'$ and $\rho'' = 0$, becomes singular only for models with $\chi + \phi = 0$. Similarly, the point $(\theta_1, \theta') = (0, \pi)$ is invariant under a $U(1)$ subgroup of (2.1) only for a matrix $R$ which takes the vector $(\rho, \rho', 0)$ into $(-\rho, \rho', 0)$. The matrix $e^{\pi I_2 R}$ has then its axis in the $(1, 2)$ plane. This implies the condition $\chi - \phi = 0$ on $R$. The same reasoning shows that the condition for singularity at $(\theta_1, \theta') = (\pi, 0)$ should be $\chi - \phi = \pi$.

Yet smaller families of models correspond to the restrictions $\psi = 0$ or $\psi = \pi$. At $\psi = 0$ the parametrization (2.26) is redundant, there is no distinction between $\chi$ and $\phi$, rather we have a one-parameter family of angle $\chi + \phi$ rotations in the $(1, 2)$ plane. For this family, both the points $(0, \frac{\pi}{2})$ and $(\frac{\pi}{2}, 0)$ are fixed points, hence singular, but not the points $(0, 0)$ and $(\frac{\pi}{2}, \frac{\pi}{2})$. The models corresponding to $\psi = \pi (a = c = 0)$ form another one-parameter family of angle $\chi - \phi$ rotations followed by a reflection in the $(1, 2)$ plane. In this case, corresponding to ref. [21], both the points $(0, 0)$ and $(\frac{\pi}{2}, \frac{\pi}{2})$ are singular but not the points $(0, \frac{\pi}{2})$ and $(\frac{\pi}{2}, 0)$.

In regions where $|W| > 2$ the dilaton is given by (2.24) with $\cos(2\theta_1)$ replaced either by $\cosh(2\theta_2)$ (when $W > 2$) or by $-\cosh(2\theta_3)$ (when $W < -2$). For a given value of $\theta'$ the dilaton becomes singular when

$$
cosh(2\theta_2) = -\frac{1 + \cos(2\theta') R_{2,2}}{R_{1,1} + \cos(2\theta') R_{3,3}} \quad \text{for } W > 2 ,
\tag{3.1}
$$

$$
cosh(2\theta_3) = \frac{1 + \cos(2\theta') R_{2,2}}{R_{1,1} + \cos(2\theta') R_{3,3}} \quad \text{for } W < -2 .
\tag{3.2}
$$

In particular, in models for which

$$
R_{1,1} > |R_{3,3}|
\tag{3.3}
$$
there is no singularity in the dilaton in the whiskers with \( W > 2 \) for any \( \theta, \theta' \). Similarly for \( W < -2 \) there will be no singularity if

\[
R_{1,1} < -|R_{3,3}| .
\]  

(3.4)

The condition (3.3) is equivalent to

\[
a^2 > b^2 , \quad c^2 < 1 ,
\]

(3.5)
as can be seen from the relations

\[
\frac{b^2}{a^2} = \frac{(1 + R_{2,2}) - (R_{1,1} + R_{3,3})}{(1 + R_{2,2}) + (R_{1,1} + R_{3,3})}
\]

(3.6)

\[
c^2 = \frac{(1 - R_{2,2}) - (R_{1,1} - R_{3,3})}{(1 - R_{2,2}) + (R_{1,1} - R_{3,3})}
\]

(3.7)

Similarly, condition (3.4) is the same as

\[
c^2 > 1 , \quad a^2 < b^2 .
\]

(3.8)

Hence, starting with a cosmological background (2.32) – (2.34) specified by the parameter \( b \), we can gradually “push,” say, a big bang singularity and the domain wall singularity to which it is connected in the whisker \( \psi' \) with \( W > 2 \) to infinity, by turning on a gauge field, parametrized by \( a, c \), keeping \( |c| < 1 \) and increasing \( |a| \) till it reaches \( |a| = |b| \). Once condition (3.5) is obtained there is no singularity at all in the whisker. A domain wall singularity will still exist in the whiskers corresponding to \( W < -2 \). The singularities are pushed to infinity in all the whiskers for the choice

\[
R_{1,1} = R_{3,3} = 0 ,
\]

corresponding to \( \psi = \frac{\pi}{2}, \phi = 0 \) in (2.26), or equivalently

\[
a^2 = b^2 , \quad c^2 = 1 .
\]

(3.10)

A particularly simple background emerges when choosing out of the models satisfying (3.9) the one with

\[
R = \begin{pmatrix}
0 & 1 & 0 \\
0 & 0 & 1 \\
1 & 0 & 0
\end{pmatrix} .
\]

(3.11)
This corresponds to \( \psi = \frac{\pi}{2}, \phi = 0, \chi = \frac{\pi}{2}, \) or \( a^2 = b^2 = c^2 = 1. \) For this background the dilaton becomes constant, \( \Phi = \Phi_0. \) The action in the region where \( |W| < 2 \) turns out to be

\[
S = \int d^2z \left\{ -\frac{k}{2\pi} \partial \theta_1 \bar{\partial} \theta_1 + \frac{k'}{2\pi} (\partial \theta' \bar{\partial} \theta' + \partial \alpha' \bar{\partial} \alpha' + \partial \beta' \bar{\partial} \beta' + 2\cos(2\theta') \partial \alpha' \bar{\partial} \beta') + \frac{1}{2\pi} \partial x \bar{\partial} x + \sqrt{k'} \cos(2\theta_1) \partial x (\bar{\partial} \beta' + \cos(2\theta')) \right\}
\]

(3.12)

This corresponds to the ordinary metric and antisymmetric tensor of \( SU(2) \) times the one-dimensional time-like \( \theta_1 \) direction times the \( x \) circular fibre, with a gauge field. At the point \( \theta_1 = 0 \) the region \( W > 2 \) is attached. There also the dilaton is constant and the action is (3.12) with \( i\theta_2 \) substituted for \( \theta_1. \) In this region \( \theta_2 \) is a space-like coordinate, while a combination of \( x, \alpha \) and \( \beta \) becomes time-like. Similarly, another constant dilaton whisker parametrized by \( \theta_3 \) is attached at \( \theta_1 = \frac{\pi}{2}. \)

We have seen that for a generic \( R \) matrix the points fixed by a continuous \( U(1) \) subgroup of gauge transformations are removed, together with their associated curvature and dilaton singularities. Yet the presence of a compact \( x \) circle does not remove orbifold type of fixed points, namely, points fixed under a discrete, infinite subgroup of gauge transformations (see appendix A). Let \( r \) be the radius of the circle parametrized by \( x. \) The gauge parameters \( \rho', \tau' \) in (2.1) are only defined modulo \( 2\pi/\sqrt{k'} \), while \( \rho'', \tau'' \) are defined modulo \( 2\pi r. \) The 4-dimensional surface on the \( SL(2) \times SU(2) \times U(1) \) group manifold corresponding to \( g(\theta) = 1, \) i.e. \( \theta = 0, \) is then invariant under a gauge transformation of the form (2.1) for which \( \rho = -\tau, \rho' = 2\pi m/\sqrt{k'}, \tau' = 2\pi n/\sqrt{k'}, \rho'' = 2\pi lr, \tau'' = 2\pi sr, \) for \( m, n, l, s \) integers. Such a gauge transformation has also to satisfy (2.3). Our choice (2.23) fixes \( \tau'' \) to 0. The matrix \( R \) has then to take a vector of the form \( (\tau, 2\pi n/\sqrt{k'}, 0) \) to the vector \( (-\tau, 2\pi m/\sqrt{k'}, 2\pi lr). \) If \( r\sqrt{k'} \) and the elements of \( R \) are rational, then there exist large enough integers \( m, n \) and \( l \) which satisfy this condition. Of course, if \( m, n, l \) satisfy it, so do any multiplication of them by a common integer. Hence the points on the surface corresponding to \( g(\theta) = 1 \) are fixed by an infinite, discrete set of gauge transformations. Otherwise, if the number \( r\sqrt{k'} \) or some elements of \( R \) are non-rational, any point on this surface is “almost” a fixed point in the sense that there exists a gauge transformation taking it to a point arbitrarily close to itself. A similar surface of fixed, or almost fixed, points under a discrete subgroup exists at \( \theta = \pi/2. \) However, eq. (2.24) implies that these orbifold fixed points do not induce any singularity in the dilaton.
The orbifold singularities are BTZ-like \[33,34\]. This can be seen, for instance, in the example (3.11), where the curvature singularities are removed completely, as follows. For simplicity, consider the case \( k = k' \). On the whisker, say \( W > 2 \), the 4-dimensional slice at \( \theta' = \pi/4 \) has the line element:

\[
d s^2 = k \left( (d\alpha')^2 + d\theta'^2 + \cosh^2 \theta d\lambda^2 - \sinh^2 \theta d\lambda_+^2 \right), \tag{3.13}
\]

where

\[
\lambda_\pm = \beta' \pm \frac{1}{\sqrt{k}} x. \tag{3.14}
\]

This is obtained from eq. (3.12) with \( \theta_1 \to i\theta_2 \), and at \( \theta' = \pi/4 \). The background (3.13) is the same as the “whisker” of an extended BTZ black hole (for instance, compare to eq. (37) in \[36\]) times an interval in \( \alpha' \). In particular, the singularity at \( \theta_2 = 0 \) is BTZ-like.

Finally, we note that when \( x \) is non-compact, the orbifold singularities are also removed. Equivalently, it is the compactification of the fifth direction \( x \) which introduces the orbifold singularities. When \( x \) is non-compact such backgrounds have some similarities with the “null brane” orbifolds introduced in \[34\].

### 3.2. Wavefunctions

The wavefunctions \( K^{ij}_{m,\bar{m}}(g) \) develop a logarithmic singularity if and only if \( |m| = |\bar{m}| \) (see \[25\] for details). In this subsection we show that singular uncharged wavefunctions exist if and only if the closed universes have a big bang and/or big crunch curvature singularities.

If we require \( m = \bar{m} \) for a vertex operator with \( q = \bar{q} = 0 \), eq. (2.39) implies \( m' = \pm \bar{m}' \). The \( m' = \bar{m}' \) solution is possible only for a matrix \( R \) in (2.39) such that \( R^T \) takes the vector \( (m, m', 0) \) into \( (-m, -m', 0) \). This implies that the axis of rotation of the matrix \( e^{\pi I_3} R^T \) lies in the \( (1, 2) \) plane. For \( R \) parametrized as in (2.26) this condition reads \( \chi + \phi = \pi \). As discussed in the previous subsection, the geometry corresponding to such an \( R \) is singular at the point \( (\theta_1, \theta') = (0, 0) \). Similarly the solution with \( m' = -\bar{m}' \) is possible for a matrix \( R \) with \( \chi - \phi = 0 \), which gives rise to a background geometry singular at \( (\theta_1, \theta') = (0, \frac{\pi}{2}) \). The function \( K^{ij}_{m,\bar{m}}(g) \) for \( m = \bar{m} \) has indeed a logarithmic singularity at \( \theta_1 = 0 \) (see \[42,23\] for details). We see then that, when \( q = \bar{q} = 0 \), condition

\[5\] Recall that in this case a certain linear combination \[42\] of the wavefunctions is regular and describes an incoming wave from the boundary of the whisker which is fully reflected \[25\].
(2.39) allows for a singular behavior of the vertex operator only in the non-generic case of a singular background geometry. Under the same condition, \( q = \bar{q} = 0 \), a vertex operator with \( m = -\bar{m} \) must, by (2.39), have \( m' = \pm \bar{m}' \). This is only possible for an \( R \) matrix with \( \chi - \phi = \pi \) or \( \chi + \phi = 0 \). Both cases give rise to a background geometry with singularity at \( \theta_1 = \frac{\pi}{2} \). Again, the vertex operator \( K^j_{m,\bar{m}}(g) \) with \( m = -\bar{m} \) has a singularity at \( \theta_1 = \frac{\pi}{2} \).

The singular operator is allowed only for a singular geometry.

If \( q \) and \( \bar{q} \) are non-zero, one can have \( m = \pm \bar{m} \) together with condition (2.39) for many \( R \) matrices which give rise to background geometries without big bang/crunch curvature singularities. The vertex operator shows then a singular behavior at \( \theta_1 = 0 \) or \( \theta_1 = \frac{\pi}{2} \) even when at these times there are no curvature singularities. Note however that these operators represent Kaluza-Klein ultra-heavy excitations from four-dimensional point of view.

4. Summary

In this paper we have turned on gauge fields in the four-dimensional family of extended universes \([21, 25]\) (parametrized by \( b^2 = \frac{1-\sin \alpha}{1+\sin \alpha} \)). This was done within the exact CFT backgrounds corresponding to \( SL(2)_x \times SU(2)_{k,k'} \times U(1)_{x} U(1)_{x} \) quotients. By a Kaluza-Klein reduction from five to four dimensions, one obtains a four dimensional time-dependent background with an Abelian gauge field (when \( k, k' \) are much bigger than the compactification radius of \( x \)).

We found that turning on a generic gauge field (parametrized by \( (a, c) \)) results in pushing the curvature big bang/crunch singularities and the domain walls connected to them towards the boundary of the whiskers. By tuning the gauge field \( (|a| \to |b|, |c| \to 1) \) the curvature singularities are removed completely and the dilaton is finite everywhere.

An orbifold singularity similar to an extended BTZ singularity remains at a time when a compact universe meets a whisker. On the other hand, if \( U(1)_x \) is non-compact, in which case the time-dependent background is five-dimensional, the orbifold singularities are removed.

Finally, using the methods of \([25]\), we found that uncharged incoming wavefunctions from the whiskers can be fully reflected if and only if there is a big bang/crunch curvature singularity, from which they are scattered, where in particular the dilaton blows up.

Appendix A. Singularities in Quotients

In this appendix, we explain the relation between singularities in quotient CFT backgrounds and fixed points in the underlying manifold under the action of a subgroup of the gauged group.

The motion of a string on a sigma-model background is described by the action

\[ \int d^2 z E_{\mu,\nu} \partial x^\mu \bar{\partial} x^\nu , \tag{A.1} \]

where \( x^\mu \) are some coordinates on the target-space manifold and

\[ E_{\mu,\nu} = G_{\mu,\nu} + B_{\mu,\nu} . \tag{A.2} \]

Here \( ds^2 = G_{\mu,\nu} dx^\mu dx^\nu \) is the line element and \( B_{\mu,\nu} dx^\mu \wedge dx^\nu \) a 2-form. A dilaton \( \Phi_0 \) is also present.

Let \( H \) be a \( d \)-dimensional isometry group of target-space. The action of \( H \) is generated by \( d \) Killing vector fields \( \xi_{(\alpha)}, \alpha = 1, \ldots, d \), which are generically independent. Gauging away this action amounts to replacing the action (A.1) by

\[ \int d^2 z E_{\mu,\nu} [\partial x^\mu + \sum_\alpha A_{(\alpha)} \xi_{(\alpha)}^\mu] [\bar{\partial} x^\nu + \sum_\beta \bar{A}_{(\beta)} \xi_{(\beta)}^\nu] , \tag{A.3} \]

where, as in section 2, \((A_{(\alpha)}, \bar{A}_{(\alpha)})\) are \( d \) gauge fields for the \( d \) isometries. Integrating out these gauge fields yields the effective \( \tilde{E} = \tilde{G} + \tilde{B} \) quadratic form corresponding to the gauged sigma-model in the space of orbits in the underlying manifold generated by the action of \( H \). Define the \( d \times d \) matrix

\[ M_{(\alpha), (\beta)} = \xi_{(\alpha)}^\mu E_{\mu,\nu} \xi_{(\beta)}^\nu . \tag{A.4} \]

The Gaussian integration of (A.3) over the gauge fields gives:

\[ \tilde{E}_{\mu,\nu} = E_{\mu,\nu} - \sum_{\alpha, \beta} E_{\mu,\nu} \xi_{(\alpha)}^\rho (M^{-1})_{(\alpha), (\beta)} \xi_{(\beta)}^\tau E_{\tau,\nu} . \tag{A.5} \]
By construction
\[ \xi_{(\alpha)}^\mu \tilde{E}_{\mu,\nu} = \tilde{E}_{\mu,\nu} \xi_{(\alpha)}^\nu = 0 \]  \hspace{1cm} (A.6)
for every \( \alpha \), namely, the gauged action is insensitive to motion along the gauge orbits. The contribution to the dilaton from this integration is
\[ \Phi = \Phi_0 - \frac{1}{2} \log(\det M) . \]  \hspace{1cm} (A.7)

At a point on the underlying manifold which is fixed under the action of some continuous subgroup of \( H \), the \( d \) Killing vectors \( \xi_{(\alpha)} \) are not independent. On the orbit corresponding to such a point \( \det M = 0 \), hence both the dilaton \( \Phi \) in (A.7) and the quadratic form \( \tilde{E} \) of (A.5) become singular. If the original metric \( G \) on the underlying manifold is not positive definite, a singularity may occur even for points which are not fixed. At such a point the \( d \) Killing vectors are independent; no combination of the \( \xi_{(\alpha)} \) vanishes. Still, some combination \( \xi = \sum \alpha a_{(\alpha)} \xi_{(\alpha)} \) may become a non-zero null vector which happens to satisfy \( \xi^\mu E_{\mu,\nu} \xi_{(\alpha)}^\nu = 0 \) for every \( \alpha \). Then again \( \det M = 0 \) and \( \Phi \) and \( \tilde{E} \) become singular. This is the origin of the “domain wall” singularities referred to in eqs. (2.35), (2.36).

Unlike the behavior near points fixed under continuous symmetry or near domain walls, where the dilaton blows up approaching them, points fixed under a discrete subgroup have a different geometrical influence. At least as far as leading behavior in \( \alpha' \) is concerned, no sign of a singularity is felt arbitrarily close to the fixed point. The singular behavior occurs only at the fixed point itself. Such are the orbifold type points discussed in section 3.
