Abstract—Considering the spectrum sharing system (SSS) coexisting with multiple primary networks, we have employed a well-designed reconfigurable intelligent surface (RIS) to control the radio environments of wireless channels and relieve the scarcity of the spectrum resource. Specifically, the enhancement of the spectral efficiency of the secondary user in the considered SSS is decomposed into two subproblems which are a second-order cone programming (SOCP) and a fractional programming of the convex quadratic form (CQFP), respectively, to optimize alternatively the beamforming vector at the secondary access point (S-AP) and the reflecting coefficients at the RIS. The SOCP subproblem is shown as a concave problem, which can be solved optimally using standard convex optimization tools. The CQFP subproblem can be solved by a low-complexity method of gradient-based linearization with domain (GLD), providing a sub-optimal solution for fast deployment. Taking the discrete phase control at the RIS into account, a nearest point searching method is also developed, realizing the discretization of the phase shifts of the RIS in practice. The simulation results indicate that both GLD and NPSP can achieve an excellent performance.

I. INTRODUCTION

In 6G era, the rapid development of digital economy and the emerging applications in consumption and business stimulate the tremendous demands about the enhancement on data rate and the availability of spectrum access. Sharing spectrum among multiple networks with different priorities is a potential technology to satisfy these demands, where secondary access points (S-APs) and secondary users (SUs) are permitted to access the same spectrum and realize data transmissions without disturbing the normal communications between the primary access points (P-APs) and primary users (PUs) in primary networks (PNs) [1]. Several PNs coexisting in the same spectrum band of citizen broadband radio service would worsen the data transmissions in the secondary network (SN) seriously [2]. Therefore, controlling the interference from the SN to PNs and improving the performance of the spectrum sharing system (SSS) is an urgent problem to be solved.

This work was supported in part by Project funded by China Postdoctoral Science Foundation Grant No.2022M710534; in part by the National Science Foundation of Chongqing, China under Grant CSTB2022NSCQ-MSX0327, cstc2021jcyj-msxmX0458; in part by the National Natural Science Foundation of China under Grants 62271092; in part by the State Key Laboratory of Integrated Services Networks (Xidian University) under grant ISN22-17; and in part by the Postdoctoral International Academic Exchange Program of Chongqing under grant 2021XSJL001.

Recently, reconfigurable intelligent surface (RIS) shows the capability of controlling and optimizing the radio environments of wireless channels between transceivers, which could improve the spectral efficiency (SE) in wireless communication systems [3]–[5]. Since the SSSs are interference-limited, RIS can alleviate the interference and strengthen the useful signals at the SUs by reconstructing the wireless channels in the SSSs. The common scenarios in RIS-aided SSSs and the mathematical methods to optimize the performance of SUs were summarized and provided in [6], respectively. The demo system of RIS-aided spectrum sharing was presented in [7] to increase the indoor network capacity significantly and relieve the overly crowded situation of spectrum resource. For the deployments of the RIS embedded in the basic SSS, the optimization for reflecting coefficients at the RIS and the power allocation of the S-AP with a single antenna are jointly designed with successive convex approximation [8]. The intelligent spectrum learning with the trained convolutional neural network is proposed in [9] to reduce the interfering signals in the received signals reflected from the RIS and maximize the signal-to-interference-plus-noise ratio (SINR) by dynamically activating the binary status of the RIS elements. When multiple PNs are involved in the scenarios, more complicated coupling of optimizing variables at the S-AP and the RIS in the SSS is introduced. Hence, the effective methods should be carefully investigated to control these variables. In particular, the discretization of the reflecting coefficients at the RIS is another concern for practical consideration about the hardware of the RIS device.

In this paper, we focus on the enhancement of SE for the SSS with multiple PNs by utilizing the RIS to manipulate wireless channels, relieving the interference between PNs and the SSS with well-designed parameters. The main contributions of this paper can be summarized as follows:

- A new system model about RIS-aided SSS coexisting with multiple PNs is established, based on which an achievable rate maximization problem is formulated. With alternative optimization (AO) utilized for multiple variables, the problem is split into two subproblems including the SOCP and the CQFP. In particular, the coupling between the RIS and the interferences is analysed.
clearly in the process of the problem formulation.

- For optimizing the beamforming vector at the S-AP, the
  SOC  subproblem is transformed equivalently into a con-
  cave problem and solved by standard convex optimization
  tools. For optimizing the reflecting coefficients of the RIS
  in the CQFP, we propose the method of greatest based
  linearization with domain (GLD) to obtain a sub-optimal
  solution with a low complexity.

- We propose the method of nearest point searching with
  penalty (NPSP) to realize the discrete quantization on the
  phase shifts of the RIS.

This paper provides the rough insights about the RIS-aided
spectrum sharing coexisting with multiple primary networks.

II. SYSTEM MODEL

In this paper, a RIS-aided SSS with J PNs is considered.
Fig. 1 shows the scenario including two PNs. The PNs
are usually controlled by the operators. Even the P-AP
is configured with multiple antennas, the beamforming vector at
the P-AP cannot be adjusted by the SSS, whose channels to
the receiver would be equivalent as an effective channel from
a P-AP configured with a single antenna. Therefore, one P-AP
and several PUs (using one PU as a typical user) configured
with a single antenna are assumed in each PN. Moreover, the
SN includes one S-AP with M antennas and one typical SU
with a single antenna. Except for the direct links from the P-
APs or the S-AP to the PUs or the SU, the transmit signals of
the P-APs or the S-AP can also be reflected by the RIS, with
the cascaded links to the PUs or the SU.

Denoting \( \theta = [\bar{\beta}_1 e^{j \theta_1}, \ldots, \bar{\beta}_N e^{j \theta_N}]^T \) composed with
the reflecting amplitude \( \bar{\beta}_n \) and the phase shift \( \phi_n \) of n-th element
on RIS \( n \in \mathcal{N} = \{1, \ldots, N\} \), the reflecting coefficients of RIS are
expressed as diagonal matrix \( \Theta = \text{diag}(\theta) \). The
direct channels from a P-AP or S-AP to a PU or SU usually
be modeled as Rayleigh channel [11]. Let \( h_j \) and \( h_{p,j,b} \)
\( j \in \mathcal{J} = \{1, \ldots, J\} \) denote direct channels from
P-AP to the corresponding PU or SU, respectively. \( h_{s,j} \in \mathbb{C}^{M \times 1} \) and \( h_{b,j} \in \mathbb{C}^{M \times 1} \) denote the direct channels from
the S-AP to the PUs and the SU, respectively. \( h_{p,j} \in \mathbb{C}^{N \times 1} \) and
\( h_{s,j} \in \mathbb{C}^{N \times M} \) are the channels from j-th P-AP and the S-AP
to the RIS, respectively. The intended link in PN refers to the
channels from RIS to j-th PU and the SU, respectively. The
channels between RIS and the APs or the users can be
modeled as Rician fading channels [11]. The received signal
of the PU in j-th PN is expressed by

\[
y_j = (h_{r,j}^H \Theta h_{p,j} + h_j) \sqrt{P_j} x_j
+ (h_{s,j}^H \Theta h_{s,j} + h_{s,j}^H) v_s \tilde{x}_s + z_j, \quad j \in \mathcal{J},
\]

where \( P_j, x_j, v_s \) and \( z_j \) denote the transmit power of the j-th P-AP,
the transmit symbol of the j-th P-AP, the beamforming vector
in the CQFP, and the white Gaussian noise at the j-th PU
with \( z_j \sim \mathcal{C}N(0, \sigma^2_{z,j}) \), respectively. The received signal
of the SU is shown as

\[
y_b = (h_{r,j}^H \Theta h_{s,j} + h_{s,j}^H) v_s \tilde{x}_s
+ \sum_{j=1}^J (h_{r,j}^H \Theta h_{p,j} + h_{p,j}^H) v_p \tilde{x}_j + z_b,
\]

where \( x_s \) and \( z_b \) denote the transmit symbol of the S-AP and
the white Gaussian noise at the SU with \( z_b \sim \mathcal{C}N(0, \sigma^2_{z,b}) \),
respectively. Then, the SINR of the SU is denoted by

\[
\gamma_b = \frac{|h_{s,j}^H \Theta h_{s,j} + h_{s,j}^H|^2}{\sum_{j=1}^J P_j |h_{r,j}^H \Theta h_{p,j} + h_{p,j}^H|^2 + \sigma^2_b}.
\]

Since the SSS is interference-limited, the noise part in \( \gamma_b \) can
be ignored. Therefore, SINR in (3) can be simplified as SIR.

The interference from the S-AP to the j-th PU is denoted as

\[
\Gamma_j = |(h_{r,j}^H \Theta h_{s,j} + h_{s,j}^H) v_s|^2, \quad j \in \mathcal{J},
\]

where \( \Gamma_j \) is restricted such that the interference from S-AP
has little impact on the normal communications in j-th PN.
Then, the maximization of the achievable rate of the SU can be
formalized as

\[
P0: \max_{\theta, \nu_s} \log_2 \left( 1 + \frac{\theta^H (H_s v_s^H H_r^H) \hat{\theta}}{\theta^H (\sum_{j=1}^J P_j \tilde{\Phi}_{j,b}^H) \hat{\theta}} \right)
\]

s.t. \( \theta^H \tilde{H}_{s,j} v_s^H \leq T_j, j \in \mathcal{J} \),

\( |\theta|_n \leq 1, n \in \mathcal{N} \),

\( |\nu_s| \leq 1 \),

\( |\nu_s| \leq P_{max} \),

where \( \theta^H = [\theta^H] \), \( \tilde{H}_{j,r,b} = [\text{diag}(h_{r,j}^H h_{r,j}) h_{p,b}]^T h_{r,j,b} \), and

\( \hat{\Phi}_{j,b} = \tilde{H}_{j,r,b} \tilde{H}_{j,r,b}^H H_s \) and \( \hat{H}_{s,j} = \left( \begin{array}{c} \text{diag}(h_{s,j}^H H_s) \\ \text{diag}(h_{s,j}^H H_s) \end{array} \right) \).

P0 is non-concave for jointly optimizing \( \nu_s \) and \( \hat{\theta} \) because
of the coupling between \( \nu_s \) and \( \hat{\theta} \) in (5a) and (5b). This
brings a big challenge to search the optimal beamforming vector
and reflecting coefficients jointly. In fact, even with
\( \nu_s \) fixed, the optimization on \( \hat{\theta} \) in P0 is still non-concave.
Since \( \hat{H}_{s,j} v_s^H \tilde{H}_{s,j} \geq 0 \) and \( \sum_{j=1}^J P_j \tilde{\Phi}_{j,b} \geq 0 \), the numerator
and denominator in the SIR of P0 are convex functions of
\( \hat{\theta} \). Although the domain of \( \hat{\theta} \) with the constraints in P0 is
a compact convex set, the fractional programming of the SIR in
P0 on \( \hat{\theta} \) is convex-concave, causing the non-concave property.

\[ \text{The extended work can be found in [10].} \]
III. ALTERNATIVE OPTIMIZATION

Since the non-concave property of the P0 causes the difficulty to obtain the optimal solution by optimizing beamforming vector and the reflecting coefficients jointly, we propose to optimize \( v_s \) and \( \hat{\theta} \) in P0 alternatively for the sub-optimal objective value. Although the thought of AO method is intuitive, the methods to optimize \( v_s \) and \( \hat{\theta} \) need to be explored based on the characteristics of each subproblem, respectively. Actually, the maximization of the achievable rate in P0 is equivalent to maximizing the SIR in P0. It can be split into two subproblems for utilizing AO, which are shown as

\[
P1: \max_{v_s} \frac{||\hat{\theta}^H H v_s||^2}{\hat{\theta}^H \left( \sum_{j=1}^J P_j \tilde{\Phi}_{j,b} \right) \hat{\theta}} \tag{6}
\]

s.t. (5b) and (5e),

and

\[
P2: \max_\theta \frac{\hat{\theta}^H (H v_s v_s^H H^H) \hat{\theta}}{\hat{\theta}^H \left( \sum_{j=1}^J P_j \tilde{\Phi}_{j,b} \right) \hat{\theta}} \tag{7}
\]

s.t. (5b), (5c) and (5d).

In the subsequent subsections, we investigate the solutions of P1 and P2, respectively.

A. The Optimal Beamforming Vector at the S-AP

With the variable \( \hat{\theta} \) fixed in P1, the SIR in P0 is optimized with the beamforming vector \( v_s \) of S-AP in P1. Since the value of objective function in P1 remains the same with \( v_s \) replaced by \( e^{i\phi} v_s \) \((\forall \phi \in [0, 2\pi])\), P1 is equivalent to P3 shown as

\[
P3: \max_{v_s} \frac{\text{Re} \left( \hat{\theta}^H H v_s \right)}{\hat{\theta}^H \left( \sum_{j=1}^J P_j \tilde{\Phi}_{j,b} \right) \hat{\theta}} \tag{8}
\]

s.t. (5b), (5c) and \( \text{Im}(\hat{\theta}^H H v_s) = 0 \),

where \( \text{Re}(\cdot) \) and \( \text{Im}(\cdot) \) denote the real part and the imaginary part of a scalar, a vector or a matrix, respectively.

For the constraints of \( v_s \) in P3, the feasible domain of \( v_s \) is a convex set. Besides, \( v_s \) in (8) is a concave function with known \( \hat{\theta} \). This implies that P3 can be verified as the maximization of a concave function on \( v_s \) with the form of SOCP [12], which can be solved with the common algorithms of convex optimization (such as interior point method). Therefore, we can obtain the optimal solution from optimizing the beamforming vector at the S-AP in the AO with the reflecting coefficients fixed.

B. The Optimization of the Reflecting Coefficients

In the design of the algorithm for CQFP, the computation complexity is important for the application in the practical system. To solve P2 in low complexity, the sub-optimal GLD is proposed to optimize the reflecting coefficients at the RIS. The general idea of GLD can be described as follows. First, P2 would be transformed as the minimization of a concave function. Then, linearization with domain would be utilized to obtain the local-optimal solution for the minimization of a concave problem, which is a sub-optimal solution for P2.

\[
P4: \min_{\theta,t} - \frac{||\hat{\theta}^H H v_s||^2}{t} \tag{9a}
\]

s.t. \( \hat{\theta}^H \left( \sum_{j=1}^J P_j \tilde{\Phi}_{j,b} \right) \hat{\theta} \leq t \), \( (5b), (5c), \) and (5d).

The problem P2 can be transformed into P4 equivalently, which is the minimization of a concave problem. The equivalence between P2 and P4 can be proven as follows.

Proof: If \( \theta_0 \) is the optimal solution for P2, define \( t_0 = \theta_0^H \left( \sum_{j=1}^J P_j \tilde{\Phi}_{j,b} \right) \theta_0 \). Then, \((\theta_0, t_0)\) is a feasible solution for P4. Assuming \((\theta_0, t_0)\) is not the optimal solution for P4, the optimal solution \((\theta_1, t_1)\) of P4 exists and \( ||(H v_s)^H \hat{\theta}||^2 / t_1 > ||(H v_s)^H \hat{\theta}_0||^2 \). Therefore,

\[
||H v_s^H \hat{\theta}_1||^2 
\]

exists, which means that \( \theta_1 \) is a feasible solution for P2 with higher value for objective function of P2, compared with the optimal solution \( \theta_0 \) for P2. This results in the contradiction with the definition of \( \theta_0 \) for P2. Therefore, \((\theta_0, t_0)\) is also an optimal solution for P4.

If \((\theta_2, t_2)\) is the optimal solution for P4, \( t_2 = \theta_2^H \left( \sum_{j=1}^J P_j \tilde{\Phi}_{j,b} \right) \theta_2 \) can be proven. The explanation is illustrated as follows. If \( t_2 \neq \theta_2^H \left( \sum_{j=1}^J P_j \tilde{\Phi}_{j,b} \right) \theta_2 \), \( t_2 > \theta_2^H \left( \sum_{j=1}^J P_j \tilde{\Phi}_{j,b} \right) \theta_2 \) is obtained with the constraints (9b). Then, a smaller value for objective function of P4 with solution \((\theta_2, t_2)\) is obtained, where \( t_2 = \theta_2^H \left( \sum_{j=1}^J P_j \tilde{\Phi}_{j,b} \right) \theta_2 \). This also results in the contradiction with the definition of \( (\theta_2, t_2) \) for P4. With \( t_2 = \theta_2^H \left( \sum_{j=1}^J P_j \tilde{\Phi}_{j,b} \right) \theta_2 \), \( \theta_2 \) is the optimal solution for P4’ shown as

\[
P4’: \min_{\theta,t} - \frac{||H v_s^H \hat{\theta}||^2}{t} \tag{9b}
\]

s.t. \( \hat{\theta}^H \left( \sum_{j=1}^J P_j \tilde{\Phi}_{j,b} \right) \hat{\theta} = t \), \( (5b), (5c), \) and (5d).

The equivalence between P2 and P4’ is obvious. With all the derivations and Illustrations shown, P2 is equivalent to P4.

Since \( f(x, t) = ||x||^2/t \) is convex over \((x, t \in \mathbb{R}_+)\), \( g(\hat{\theta}, t) \triangleq -||(H v_s)^H \hat{\theta}||^2/t \) is convex over \((\hat{\theta}, t \in \mathbb{R}_+)\). As P4 is the minimization over the concave problem, the common methods in convex optimization to solve the minimization over a convex function for the optimal solution could not be utilized. However, the approximation of the concave objective function in P4 with linearization can be considered to obtain a sub-optimal solution for P4. Linear approximation is the variation of Taylor expansion by cutting off the Lagrange form of the remainder or the Peano form of the remainder, which is in second order. Therefore, the value of the linear approximation for the objective function in P4 is higher than...
the optimal value in P4 for the convexity of the function $||x||^2/t$, which can explain the sub-optimality of GLD.

With $w^T = \begin{bmatrix} \theta^T & t \end{bmatrix}$ defined, linearization is utilized to make $q(w)$ convexified on $w_k$ as

$$q(w; w_k) \triangleq q(w_k) + \nabla q(w_k)^T(w - w_k), \quad (10)$$

where $q(w; w_k)$ is an affine function with convexity and $k$ is the count number of the iteration in the GLD. The domain of $w$ is $D$ determined by the constraints (5b), (5c), (5d) and (9b), and the convexity of the domain can be easily validated.

To keep any feasible point for the problem (10) in $D$, the penalty item should be added in (10) for the points out of $D$. The linearization for P4 with domain is shown as

$$\tilde{q}(w; z) \triangleq q(z) + \nabla q(z)^T(w - z) + \mathcal{I}(w), \quad (11)$$

Since $I(w)$ is a convex function and (10) is an affine function, $\tilde{q}(w; z)$ in (11) is convex. The gradient of $q(w)$ can be obtained as

$$\nabla q(w)^T = [-\hat{H}^T(\hat{H}_s v_j v_j^H H_0^H)/t] + |(\hat{H}_s v_j)^H\theta|^2/t^2]. \quad (12)$$

Since the optimization of (10) includes the process of iteration for $w_k$, $w_k$ may be on the boundary of $D$. Therefore, the convex function $q(w; w_k)$ may not be differentiable at $w_k$. If $w_k$ in $q(w_k)$ is on the boundary of $D$, the damped process as $w_k = \varepsilon w_{k-1} + (1 - \varepsilon) w_{k-1}$ is executed with $\varepsilon \in (0, 1)$. If $w_0$ is in the interior of $D$, $w_k$ will be guaranteed in the interior of $D$.

In the initial phase, the GLD attempts to obtain a feasible solution for P4 randomly. With this feasible point in the domain of P4, the objective function in P4 would be approximated by a line segment with the linearization operation. The optimal solution for the line segment in the feasible domain of P4 is solved as the updated feasible point to start next iteration. Therefore, the iteration of the $w_k$ would converge to a local minimum point of the objective function in P4, which is a sub-optimal solution of the reflecting coefficients at the RIS.

In summary, the GLD algorithm is shown as Algorithm 1, whose comutation complexity is proportional to $O(KN)$.

IV. THE PRACTICAL CONSIDERATION FOR THE RIS

Although the phase shifts of reflecting coefficients in P0 are continuous variables ranging in $[0, 2\pi]$, the phase shifts of the RIS in practical system are selected from discrete values for the characteristics of the RIS devices. Usually, the phase shifts can be quantized by 1 bit or 2 bits [11]. If the phase shifts of $\theta$ in P0 are discrete variables, P0 will become a mixed integer non-linear problem (MINLP), which is more complicated to be solved. The discrete phase shifts of $\theta$ can be relaxed to continuous variables to obtain the solution, which is corresponding to P0. Then, the continuous solution can be quantized to discrete phase shifts. However, new solution should be feasible for the constraints (5b) and decrease the deterioration of SE performance. Assuming that $\theta$ is a continuous solution for P0 and there are $L$ levels ($\{\phi_1, \cdots, \phi_L\}$) for the quantization of phase shifts, the quantization problem about the phase shifts of the reflecting coefficients can be illustrated as

$$\text{P5: } \min_{\theta_i} \|\hat{\theta} - \theta_d\|^2 \quad \text{s.t. } \gamma([\theta_d]_n) \in \{\phi_1, \cdots, \phi_L\}, n \in N, \quad \|\theta_d\| H_{s,j} v_s \leq \Gamma_j, j \in J. \quad (13a, 13b, 13c)$$

For a small number of reflecting coefficients, the exhaustive searching method can be utilized to obtain the discrete solution $\theta_d$, which should conform to the constraints of (5b) and optimize the objective function of P0.

In this paper, the NPSP is proposed to obtain the sub-optimal solution about the discrete phase shifts. The NPSP method would focus on searching the nearest point in the candidate set of the discrete phase shifts, where the objective function would be added with the penalty for invalidation of constraints. Let us introduce an auxiliary vector $b$ for $\theta_d$. Then, the problem about NPSP for solving discrete phase shifts at the RIS is formulated as

$$\text{P6: } \min_{\theta_d, b} \|\hat{\theta} - \theta_d\|^2 + \mu/2\|b - \theta_d\|^2 \quad \text{s.t. } b = \theta_d, \quad (13b), \text{ and } (13c),$$

where $\mu > 0$ is the penalty parameters. Given the Lagrange variables $w = [w_1, \cdots, w_J]^T \succeq 0$ and $\lambda = \lambda_R + i\lambda_I$ ($\lambda_R = [\lambda_{R,1}, \cdots, \lambda_{R,N}]^T$ and $\lambda_I = [\lambda_{I,1}, \cdots, \lambda_{I,N}]^T$) for $\Re{\{b - \theta_d\}} = 0$ and $\Im{\{b - \theta_d\}} = 0$, the Lagrangian function for P6 is

$$G(b, \theta_d, \lambda, w) = (b - \hat{\theta})^H(b - \hat{\theta}) + \mu/2(b - \theta_d)^H(b - \theta_d)$$

$$+ \sum_{n=1}^{N} I_n([\theta_d]_n) + \Re{\{\lambda^H(b - \theta_d)\}}$$

$$+ \sum_{j=1}^{J} w_j([\theta_d]^H H_{s,j} v_s)^2 - \Gamma_j), \quad (15)$$

Algorithm 1 The Gradient-based Linearization with Domain algorithm for P4

1: Initial: given $w_0$ in interior of $D$ randomly, $\tau_0 = q(w_0)$, $\tau_{-1} = -\infty$, $k \leftarrow 0$, set $K$ with a large positive integer.
2: while $\tau_k > \tau_{k-1} \& \& k < K$ do
3: Linearization with domain: $q(w; w_k) = q(w_k) + \nabla q(w_k)^T(w - w_k) + \mathcal{I}(w)$.
4: Solve the convex subproblem of minimizing $q(w; w_k)$ with interior point method and obtain the solution $w_{k+1}$ for $\tau_k = \min_w q(w; w_k)$ with the constraints (5b), (5c), (5d) and (9b).
5: if $w_{k+1}$ is in the interior of $D$ then
6: $w_{k+1} \leftarrow w_{k+1}$
7: else
8: $w_{k+1} \leftarrow \varepsilon w_k + (1 - \varepsilon) w_{k-1}, \varepsilon \in (0, 1)$.
9: end if
10: $k \leftarrow k + 1$
11: end while
where $\mathcal{I}_n(x)$ is the indicator function ($\mathcal{I}_n(x) = 1$ if $x \in \{[|\theta_1|, e^{j\theta_1}], \ldots, [|\theta_n|, e^{j\theta_n}]\}$, otherwise $+\infty$). Then, the dual problem can be defined as

$$\mathcal{L}(\lambda, w) \triangleq \inf_{b, \theta_d} \mathcal{G}(b, \theta_d, \lambda, w)$$

To solve P6 with the NPSP, the iterations about the parameters are shown as

$$\theta_d(k+1) = \arg \min_{\theta_d} \mathcal{G}(b(k), \theta_d, \lambda(k), w(k)), \quad (17a)$$

$$b(k+1) = \arg \min_b \mathcal{G}(b(k), \theta_d(k+1), \lambda(k), w(k)), \quad (17b)$$

$$\lambda(k+1) = \lambda(k) + \mu(b(k+1) - \theta_d(k+1)), \quad (17c)$$

$$w_j(k+1) = w_j(k) + \mu(\theta_d(k+1)H_{s_j}v_s - T_j)^+, \quad j \in J. \quad (17d)$$

Since $(H_{s_j}v_s)^H(H_{s_j}v_s)$ is a real number, the angle calculation is shown as

$$\angle\left(\frac{b(k) + \lambda(k)/\mu}{1 + \sum_{j=1}^{J} w_j(H_{s_j}v_s)^H(H_{s_j}v_s)}\right) = \angle\left(b(k) + \frac{\lambda(k)}{\mu}\right).$$

Therefore, $\theta_d(k+1)$ in (17a) can be solved by

$$\angle(\theta_d(k+1)) = \arg \min_{\varphi} ||\varphi - \angle\left(b(k) + \lambda(k)/\mu\right)||, \quad (18)$$

$$[\varphi]_n \in \{\phi_1, \ldots, \phi_L\}, \quad [\theta_d(k+1)]_n \triangleq [\theta]_n, \quad n \in N.$$ 

Besides, $b(k+1)$ in (17b) can be solved by

$$b(k+1) = Y^{-1}\left(2\theta_d + \mu\theta_d(k+1) + \lambda(k+1)\right), \quad (19)$$

where $Y = (2 + 2\mu)I_N + 2\sum_{j=1}^{J} w_j(k)(H_{s_j}v_s)(H_{s_j}v_s)^H$. Then, the proposed NPSP algorithm to solve P6 problem can be shown as Algorithm 2, whose computation complexity is proportional to $O(N_{\text{itr}}(N(N + 1) + JM + N^3))$.

Since $\theta_d$ is the discretization of the $\hat{\theta}$, the constraints of (13c) may become invalid. Therefore, the feasible $\theta_d$ may not exist for some CSI $H_{s_j}$ and the beamforming vector $v_s$, especially with a small number of elements at the RIS.

V. SIMULATION RESULTS AND DISCUSSIONS

In this section, simulation results are shown to evaluate the performance of RIS-aided spectrum sharing with multiple PNs. Four P-APs and the S-AP are placed at (50 m, -86.6 m, 0 m), (86.6 m, -50 m, 0 m), (86.6 m, 50 m, 0 m), (50 m, 86.6 m, 0 m), and (100 m, 0 m, 0 m), respectively. The PUs and the SU are randomly distributed in the circle with the center (2 m, 0 m, 1 m) and the radius $r_u = 1$ m. The center of the RIS is placed at (0 m, 0 m, 2 m). Other parameters are given in Table I [13]. In particular, due to the double fading effect [3], the path loss of the cascaded link over RIS is larger than that of the direct link.

Fig. 2 shows the SE performance of the proposed GLD with the varying parameter $N$ of the RIS as $P_{\text{max}}$ of the S-AP increases from $-2$ dBm to 14 dBm. Compared with the scenario without RIS, RIS-aided SSS has obvious gain on the SE performance, even with $N = 1$. For the objective function of P2, the increasing on the parameter $N$ of the RIS not only provide more flexibility on the optimization of the numerator in P2, may also amplify or diminish the denominator in P2.

Algorithm 2 The Nearest Point Searching with Penalty algorithm for P6

1. Initial: given $\lambda^{(0)}$, $b^{(0)}$, and $w^{(0)}$ randomly, $F_{\text{obj}} \leftarrow +\infty$, $k \leftarrow 0$. Set the terminating threshold $\varsigma$ for objective function in P5 and $N_{\text{itr}}$ for maximum number of iteration.

2. While $F_{\text{obj}}(k) > \varsigma$ & $k < N_{\text{itr}}$ do

3. Update $\theta_d^{(k+1)}$, $b^{(k+1)}$ with (18) and (19).

4. if $\theta_d^{(k+1)}$ meets the constraints in (13c) then

5. $\theta_d \leftarrow \theta_d^{(k+1)}$.

6. $F_{\text{obj}} \leftarrow F_{\text{obj}}^{(k)}$.

7. end if

8. $F_{\text{obj}}^{(k+1)} \leftarrow \min\{||\theta - \theta_d^{(k+1)}||^2, F_{\text{obj}}^{(k)}\}$

9. end if

10. Update $\lambda^{(k+1)}$, $w^{(k+1)}$ with (17c) and (17d).

11. $k \leftarrow k + 1$.

12. end while

13. if $F_{\text{obj}}^{(k)} = +\infty$ & $k = N_{\text{itr}}$ then

14. The feasible solution for $\theta_d$ is not searched.

15. else

16. Output $\theta_d$.

17. end if

| Parameters | Values |
|------------|--------|
| Path loss for RIS-assisted channel | 35.6+22.0 lg d |
| Path loss for direct channel | 32.6+36.7 lg d |
| The maximum transmit power ($P_{\text{max}}$) | -2 dBm ~ 14 dBm |
| The interference threshold ($\bar{T}_j$) | -115 dBm, $j \in J$ |
| The power of a P-AP ($P_j$) | 10 dBm, $j \in J$ |

![Fig. 3](image.png)

Fig. 3 shows the SE performance of the proposed GLD and the benchmark semidefinite programming (SDP) method as the interference threshold of each PN $\bar{T}_j$ increases.
more PNs involved in the scenarios of spectrum sharing, the SE performance of the system decreases sharply for more interference introduced in the denominator of $\gamma_b$ and more constraints added in (5b), which is shown in Fig. 3. Besides, the enhancement on the SE performance of the SU becomes more obvious for the scenarios with a larger number of PNs as the interference threshold goes up.

For the practical consideration about the reflecting coefficients, the proposed NPSP is utilized to quantize the phase shifts of the reflecting coefficients $\hat{\theta}$ at the RIS for the proposed GLD and the benchmark SDP method. Fig. 4 shows the performance of GLD and SDP with the embedded NPSP for the phase discretization of $\hat{\theta}$. The discretization of $\hat{\theta}$ decreases the achievable rate of the SU slightly for the proposed GLD and the benchmark SDP method with $J = 2$ or 3. Besides, the achievable rate of SU about the proposed GLD with NPSP embedded for the phase discretization of $\hat{\theta}$ is still better than that of benchmark SDP method in the same case. It is worth noting that the achievable rate of the SU with the phase discretization of $\hat{\theta}$ encounters the sharp decreasing with a small $N$, compared with that of continuous value of $\hat{\theta}$. When $N$ is small, the phase discretization of $\hat{\theta}$ may result in the invalidation about the constraints in (13c).

VI. CONCLUSION

In this paper, the problem about maximizing the achievable rate of the SU in RIS-aided SSS with multiple PNs was formulated, which was split into a SOCP subproblem and a CQFP subproblem, respectively. The SOCP subproblem has been proven to be concave, which can obtain the optimal solution with the common algorithms of convex optimization. To decrease the computation complexity, we developed the sub-optimal GLD to solve the CQFP subproblem. Although more PNs would decrease the SE performance of the SU due to more interference introduced in the system, our proposed GLD can improve the achievable rate of the SU compared with the traditional SDP method. Besides, the NPSP algorithm was proposed to realize the discretization of phase shifts about the reflecting coefficients at the RIS in practical system. The RIS can amplify the effective signals and suppress the interference of the SU by empowering the radio environments of wireless channels, which improves the SE performance of the SSS coexisting with multiple PNs significantly.
