Probing interfacial pair breaking in tunnel junctions based on the first and the second harmonics of the Josephson current

Yu. S. Barash
Institute of Solid State Physics, Russian Academy of Sciences, Chernogolovka, Moscow District, 142432 Russia

It will be shown that a pronounced interfacial pair breaking can be identified in Josephson tunnel junctions provided the first \( j_{1c} \) and the second \( j_{2c} \) harmonics of the supercurrent, as well as the depairing current in the bulk \( j_{dp} \), are known. Namely, within the Ginzburg-Landau theory a strong interfacial pair breaking results in the relation \( j_{2c} j_{dp} \gg j_{1c}^2 \), while in standard junctions, with negligibly small pair breaking, the relation of opposite character takes place.

I. INTRODUCTION

A remarkable property of superconducting weak links is that the local conditions in a small transition region control the whole process of charge transport. For the same reason, interface-induced suppression of the superconducting condensate density can have a considerable influence on the Josephson effect. A strong surface pair breaking has been theoretically established for various unconventional superconductors as well as for magnetic interlayers under certain conditions\(^{1-9} \). Therefore, probing the condensate density near the interface would provide valuable information for studying and controlling fundamental characteristics of the superconducting junctions. It is still an ongoing problem for the junctions though the order parameter profiles near superconductor-vacuum surfaces have been recently determined using a Scanning Tunneling Microscopy method with a superconducting tip\(^{10} \).

In superconducting tunnel junctions the first harmonic \( j_1 = j_{1c} \sin \chi \) usually strongly dominates the Josephson current \( j = j_{1c} \sin \chi + j_{2c} \sin 2\chi + \ldots \), while the second harmonic \( j_2 = j_{2c} \sin 2\chi \) represents a small correction to the first one, \( |j_{2c}| \ll |j_{1c}| \), mostly due to a small junction transparency. Qualitatively different phase dependencies of the two harmonics allow to study and distinguish between them experimentally. It is therefore of interest to find out, which characteristic properties of the superconducting junctions can be identified with the data provided by the two harmonics. Thus the first harmonic, as opposed to the second one, is known to be noticeably suppressed both at 0-\( \pi \) transitions as well as in the junctions involving unconventional superconductors with special interface-to-crystal orientations\(^{11-18} \). However, except for these special cases, the relation \( |j_{2c}| \ll |j_{1c}| \) always takes place and does not qualitatively discriminate between various superconducting tunnel junctions.

This paper suggests a test, which will be derived within the Ginzburg-Landau (GL) theory and will allow identification of a pronounced interfacial pair breaking in tunnel junctions, provided the first and the second harmonics, as well as the depairing current in the bulk \( j_{dp} \), are known. The relation \( j_{2c} j_{dp} \gg j_{1c}^2 \) will be shown to take place in tunnel junctions with a strong interfacial pair breaking, while in standard tunnel junctions, with negligibly small pair breaking, it will be \( j_{2c} j_{dp} = 0.27 j_{1c}^2 < j_{1c}^2 \). The specific temperature dependencies of the two harmonics near \( T_c \) will also be determined. The self-consistency is shown to alter existing estimates of both harmonics considerably.

II. BASIC EQUATIONS

Consider tunnel junctions with the spatially constant width, which is much less than the Josephson penetration length, and with a plane interlayer at \( x = 0 \) of zero length within the GL approach. Assume the usual form of the GL free energy, which applies, for example, to \( s \)-wave and \( d_{x^2−y^2} \)-wave junctions: \( F = F_{b1} + F_{b2} + F_{int} \). Here \( F_{b1(2)} \) are the bulk free energies of two superconducting leads and \( F_{int} \) is the interface free energy. For a junction with two identical superconductors, the bulk free energies have identical coefficients:

\[
F_{b1(2)} = \int_{V_{1(2)}(x)} \left( K |\nabla \Psi_{1(2)}|^2 + a |\Psi_{1(2)}|^2 + (b/2) |\Psi_{1(2)}|^4 \right) dV_{1(2)}. \tag{1}
\]

Here \( K, b, a > 0 \), \( a = a \tau = -\alpha (T_c - T)/T_c \).

Asymmetry can be generally maintained by different conditions on the opposite sides of the interface, as in \( d \)-wave junctions with different crystal-to-interface orientations, and/or in junctions with asymmetric magnetic interfaces. Then the interface free energy incorporates different contributions from the two superconducting banks:

\[
F_{int} = \int_{S_{12}} \left[ g_{11} |\Psi_1|^2 + (1/2) h_{11} |\Psi_1|^4 + g_{22} |\Psi_2|^2 + (1/2) h_{22} |\Psi_2|^4 + h_{12} |\Psi_1|^2 |\Psi_2|^2 + (g_{12} + \eta_1) |\Psi_1|^2 + \right]
\]

\[
+(g_{12} + \eta_2) |\Psi_2|^2 \right] dS_{12},
\]

where \( k_{12}, \eta_1, \eta_2 > 0 \) are the interface potential coefficients. The GL free energy, which applies, for example, to \( s \)-wave and \( d_{x^2−y^2} \)-wave junctions: \( F = F_{b1} + F_{b2} + F_{int} \).
\[ + \eta_2 |\Psi_2|^2 |\Psi_1 - \Psi_2|^2 + f_{12} |\Psi_1^2 - \Psi_2^2|^2 dS. \tag{2} \]

In addition to the main terms, which are quadratic or bilinear in the order-parameter moduli, the quartic and biquadratic terms of the next order of smallness near \( T_c \) are kept in (2). In tunnel junctions with small transparencies \( D \ll 1 \) one gets \( g_{12}, \eta_1, \eta_2 \propto D, \ h_{12}, f_{12} \propto D^2. \)

For the order parameter \( f(x)e^{ix(x)} \) normalized to \( f = 1 \) in the bulk without superflow, the first integral of the GL equation in the presence of the supercurrent\(^{19} \) takes the form

\[ \left( \frac{df}{dx} \right)^2 + f^2 - \frac{1}{2} f^4 + \frac{4\bar{J}^2}{2f^2} = 2f_{\infty}^2 - \frac{3}{2} f_{\infty}^4. \tag{3} \]

Here \( \bar{x} = x/\xi, \ \xi = \sqrt{K/|a|} \) is the temperature dependent superconducting coherence length, \( \bar{j} \) is the spatially constant normalized current density \( j = j/\bar{j}_d = -3(\sqrt{3}/2)(dx/dx)f^2, \ \bar{j}_d = 8|e|K^{1/2}|a|^{3/2}/3\sqrt{3}h b \) is the depairing current in the bulk, and \( f_{\infty} \) is the asymptotic value of \( f \) in the depth of the superconducting leads.

The boundary conditions (BC) originate from the variation of \( F_{int} \) and from the bulk gradient terms integrated by parts. One starts with the BC in standard linear approximation in \( f_1(-0) \equiv f_{10} \) or \( f_2(+0) \equiv f_{20}. \) Taking real and imaginary parts of the BC for the complex quantity \( f(x)e^{ix(x)} \), one finds the following linear BC and the expression for the supercurrent

\[ \left( \frac{df_i}{dx} \right)_0 = (-1)^i (\bar{f}_{i2} + g_{i2}f_{20} - g_{i2}\cos \chi f_{20}, \tag{4} \]

\[ \bar{j} = (3\sqrt{3}/2)\bar{f}_{12}f_{10}f_{20}\sin \chi. \tag{5} \]

Here \( i = 1, 2, \bar{t} = 3 - i. \) The phase difference of the order parameters across the interface is \( \chi = \chi_{10} - \chi_{20}, \) and \( \bar{g}_{i2} = g_{i2}\zeta(T)/K, \ \bar{g}_{11} = g_{11}\zeta(T)/K \) and \( \bar{g}_{22} = g_{22}\zeta(T)/K \) are the effective dimensionless coefficients.

For tunnel junctions \( |\bar{g}_{i2}| \ll 1. \) Since the order parameters near pair-breaking interfaces vary on a scale \( \gtrsim \zeta(T), \) one gets from (4) \( \bar{g}_{i2}f_{20} \ll 1, \) on account of \( |\bar{g}_{i2}|f_{20} \ll 1. \) This signifies, in particular, that for \( \bar{g}_{i2} \gg 1 \) a strong interfacial pair breaking \( f_{20} \ll \bar{g}_{i2}^{-1} \ll 1 \) occurs.

### III. TEST FOR A PRONOUNCED INTERFACIAL PAIR BREAKING

Consider the supercurrent within the second order perturbation theory in \( \bar{g}_{12}. \) Then, according to (5), quantities \( f_{10} \) and \( f_{20} \) should contain the terms of the zeroth and the first orders of smallness. One takes \( x = 0, \pm 0 \) in (3) and substitutes there (4) and (5). Since the depairing effects in the bulk would contribute to (3) only beginning with the second order terms, within the given accuracy \( f_{\infty} = 1. \) Then one obtains the following equations for \( f_{10} \) and \( f_{20} \)

\[ f_{i0}^4 - 2(1 + \bar{g}_{i2}^2)f_{i0}^2 + 1 = 4\bar{g}_{i2}\bar{g}_{i1}f_{i0}(f_{i0} - f_{30}\cos \chi). \tag{6} \]

In the zeroth order in \( \bar{g}_{i2} \) the solutions are

\[ f_{i0}^{(0)} = (1/2)\left( \sqrt{2 + \bar{g}_{i1}^2} - \bar{g}_{i1} \right)^2, \quad i = 1, 2. \tag{7} \]

Eq. (7) involves two solutions of (6). At \( g_{i1} > 0 \) it describes a pair breaking \( f_0 < 1, \) and then \( |df_{i0}/dx|_0 < 1/\sqrt{2}. \) At \( g_{i1} < 0 \) an enhanced superconductivity at the boundary \( f_0 > 1 \) occurs\(^{20-24} \). Then the quantity \( |df_{i0}/dx|_0 > \sqrt{2}g_{i1} \) can take large values, and a strong enhancement would induce a characteristic scale substantially less than \( \xi(T) \) of the leads (see Appendix for details).

The first order corrections \( f_{0i} \approx f_{i0}^{(0)} + f_{0i}^{(1)}, \) which follow from (6) and (7), are

\[ f_{i0}^{(1)} = -\bar{g}_{i2}(f_{i0}^{(0)} - f_{0i}^{(0)}\cos \chi)/\sqrt{2 + \bar{g}_{i1}^2}. \tag{8} \]

Substituting the order parameters \( f_{0i} \) in (5), one finds the first and the second harmonics of the supercurrent \( j = j_{13}\sin \chi + j_{23}\sin 2\chi \) in the Josephson tunnel junctions

\[ \bar{j}_{13} = \frac{3}{8}\sqrt{3}g_{12}\frac{\bar{f}_{12}^2}{2 + \bar{g}_{i1}^2 - \bar{g}_{i2}^2} \times \left[ 1 - \frac{\bar{g}_{i1}^2 - \bar{g}_{i2}^2}{\sqrt{2 + \bar{g}_{i1}^2} - \sqrt{2 + \bar{g}_{i2}^2}} \right]. \tag{9} \]

\[ \bar{j}_{23} = \frac{3}{8}\sqrt{3}g_{22}\frac{\bar{f}_{12}^2}{2 + \bar{g}_{i1}^2 - \bar{g}_{i2}^2} \times \left[ 1 - \frac{\bar{g}_{i1}^2 - \bar{g}_{i2}^2}{\sqrt{2 + \bar{g}_{i1}^2} - \sqrt{2 + \bar{g}_{i2}^2}} \right]. \tag{10} \]

The second harmonic (10) is induced by the proximity across the interface. At \( g_{i1} < 0, \) the quantity \( |g_{i1}| \) is here assumed not to be too large to retain \( |\bar{j}_{13}| \ll 1 \) and \( |g_{i2}| \ll \sqrt{K}a. \) Otherwise, Eqs. (9) and (10) are applicable at any values of \( \bar{g}_{i1} \)\(^{25} \). Further, the small second and third terms in the square brackets in (9) will be neglected.

One finds from (9) and (10) the following relationship between the amplitudes \( j_{12} \) and \( j_{13}: \)

\[ \bar{j}_{12} = \frac{1}{6\sqrt{3}} \sum_{i=1,2} \frac{1}{\sqrt{2 + \bar{g}_{i1}^2 - \bar{g}_{i2}^2}} \left( \sqrt{2 + \bar{g}_{i1}^2} + \bar{g}_{i2} \right)^2. \tag{11} \]

Under the conditions \( |\bar{g}_{i1}| \ll 1, \) \( j_{12} \) can disregard the interfacial proximity effects. Then in the original units \( j_{12} \propto \sqrt{\bar{r}}, j_{13} \propto \sqrt{\bar{r}} \), while the relative magnitudes of the two harmonics are described by the equalities

\[ j_{12}/j_{13} = 0.27j_{23}^2, \quad j_{12} = 0.7\bar{g}_{12}j_{13}. \tag{12} \]

Consider now asymmetric junctions with a pronounced interfacial pair breaking on one side of the interface, when \( |\bar{g}_{i1}| \ll 1 \) and \( \bar{g}_{i2} \gg 1, \bar{g}_{22} > 0. \) In d-wave junctions this can take place for interface-to-crystal orientations, which are close to (100) and (110) orientations on the opposite banks of a smooth interface. Then Eqs. (9)
and (10) are reduced to \( j_{c1} \approx 3\sqrt{3}g_{12}/(2\sqrt{2}g_{22}) \), \( j_{c2} \approx 3\sqrt{3}g_{12}^2/(4g_{22}) \) while \( j_{c1} \propto |\tau|^{3/2} \), \( j_{c2} \propto |\tau| \) in the original units. The relationships between the harmonics are

\[
j_{c2}j_{dp} = 0.385\tilde{g}_{22}j_{c1}^2, \quad j_{c2} = 0.7\tilde{g}_{12}j_{c1}.
\]  

(13)

In symmetric junctions with \( \tilde{g}_{11} = \tilde{g}_{22} > 0 \) and \( \tilde{g}_{ii}^2 \gg 1 \) one gets from (9) and (10) \( j_{c1} = 3\sqrt{3}g_{12}/4\tilde{g}_{22} \), \( j_{c2} = 3\sqrt{3}g_{12}^2/4\tilde{g}_{22}^2 \). Hence, \( j_{c1} \propto \tau^2 \), \( j_{c2} \propto \tau^2 \), and

\[
j_{c2}j_{dp} = 0.77\tilde{g}_{22}j_{c1}^2, \quad j_{c2} = (\tilde{g}_{12}/\tilde{g}_{22})j_{c1}.
\]  

(14)

In symmetric junctions the quantity \( \tilde{j}_{c2}/j_{c1} \propto \tilde{g}_{22}^{-1} \) diminishes with increasing pair breaking\(^{26}\).

It also follows from (9)-(11) that \( j_{c2}j_{dp} = 0.136 j_{c1}^2 \) for \( |\tilde{g}_{11}| \ll 1 \) and \( \tilde{g}_{22}^2 \gg 1 \), \( \tilde{g}_{22} < 0 \). In symmetric junctions with \( \tilde{g}_{ii}^2 \gg 1 \), \( \tilde{g}_{ii} < 0 \) one gets \( j_{c2}j_{dp} = 0.19 j_{c1}^2/|\tilde{g}_{22}|^3 \).

Under the conditions \( \tilde{g}_{11} < 0 \), \( \tilde{g}_{22} > 0 \), \( \tilde{g}_{ii}^2 \gg 1 \) (\( i = 1, 2 \)) the relation is \( j_{c2}j_{dp} = 0.385\tilde{g}_{22}j_{c1}^2 \).

Comparing (12), (13) and (14), as well as the results for \( \tilde{g}_{ii} < 0 \), one can conclude that the quantity \( j_{c2}j_{dp}/j_{c1}^2 \) always exceeds unity, when a pronounced interfacial pair breaking \( \tilde{g}_{ii}^2 \gg 1 \), \( \tilde{g}_{ii} > 0 \) takes place on at least one side of the interface. At \( 0.4\tilde{g}_{22} \gg 1 \), the strong inequality \( j_{c2}j_{dp} 
\]

(12)

The resulting formula is obtained after replacing \( \tilde{g}_{12} \) for \( j_{c1} \) and \( j_{c2} \) for \( j_{c1} \) in the whole temperature range is of interest for further theoretical and experimental studies.

### IV. MICROSCOPIC FORMULA FOR \( \tilde{g}_{12} \)

Microscopic expressions for \( \tilde{g}_{12} \) and for \( \tilde{g}_{ii} \) (\( i = 1, 2 \)) can be obtained by comparing the Josephson currents of the GL theory with the corresponding microscopic results near \( T_c \). Consider here standard symmetric SIS tunnel junctions with the negligibly small pair breaking \( |\tilde{g}_{ii}| \ll 1 \). Then the GL expression for the first harmonic should coincide with the microscopic Ambegaokar-Baratoff formula\(^{31}\) near \( T_c \):

\[
j_{c1} = |4e||a||\tilde{g}_{12}/(hh)| = |\pi|\Delta^2/(4|e|TR_N).\]

Here \( R_N \) is the junction resistance in the normal state. Since \( K = h^2/4mk, |a| = \alpha|\tau| \) and, in the absence of the pair breaking, the BCS gap function near \( T_c \) is \( |\Delta|^2 = 8\pi^2(T_c - T)/(|\tau|\zeta(3)), \) one obtains

\[
\tilde{g}_{12} = 2\pi^3T(mb\xi(T))/(\zeta(3)e^2haRN).
\]

(15)

Eq. (15) can be transformed further with the Gor’kov’s microscopic formulas for \( b/\alpha \) and with the junction resistance expressed via the averaged transparency \( R_N' = e^2k_fD/4\pi^2h \). Thus for dirty junctions one obtains

\[
\tilde{g}_{12} = 0.75\tilde{T}(\xi(T)/\ell), \quad \text{while for pure junctions } \tilde{g}_{12} = 3\pi^2\tilde{T}(\xi(T)/(\zeta(3)\zeta_0)) = 1.76\tilde{T}(\xi(T)/\zeta_0).\]

Here \( \ell \) is the mean free path and \( \zeta_0 = hv_f/\tau T_c \) is the zero-temperature coherence length. The quantitative microscopic formulas obtained here for \( \tilde{g}_{12} \) agree with the earlier estimates\(^{26}\).

In particular, in dirty superconductors the ratio \( \xi(T)/\ell \) can easily reach 100 even at low temperatures. Hence, for small and moderate transparencies the quantity \( \tilde{g}_{12} = 0.75\tilde{T}(\xi(T)/l) \) can vary from vanishingly small values in the tunneling limit considered in this paper to those well exceeding 100 near \( T_c \), when a substantial anharmonic behavior of the Josephson current takes place\(^{26}\).

### V. NEXT ORDER TERMS IN THE CURRENT

The initial expression (5) for the supercurrent can be generalized to include the next order terms, which originate from the phase dependent biquadratic contributions to (2). The resulting formula is obtained after replacing \( \tilde{g}_{12} \to \tilde{g}_{12} + \tilde{g}_{12}(|a|/b)f_{10} + \tilde{g}_{12}(|a|/b)f_{20} \) in (5) and adding \( j_{c3}(T = 0) = \pi\Delta_0/2e|RN| \). Hence \( j_{c1,0}/j_{c1}(T = 0) = 2.66 \). Despite the value it would have for analyzing the experimental results\(^{10}\), there still is no microscopic theory for the effects of strong interfacial pair breaking in a wide temperature range. If, qualitatively, no dramatic changes of behavior take place and \( \tilde{g}_{ii,0} \gg 1 \), the relation \( j_{c2}j_{dp} \) could remain valid with decreasing temperature below the GL domain of applicability unless anomalous temperature dependencies, if present, come into play, e.g., due to Andreev bound states with low energies \( \varepsilon_B < \Delta_0 \). The temperature dependence of \( (j_{c2}j_{dp}/j_{c1}^2) \) in the whole temperature range is of interest for further theoretical and experimental studies.
\[ \tilde{j}_{f12} = \tilde{j}_{c2,f} \sin 2\chi, \]
\[ \tilde{j}_{c2,f} = (3\sqrt{3}/2)(|a|/b)\tilde{f}_{12}f_{10}^2f_{20}, \]
(16)

Here \( \tilde{f}_{12} = f_{12}(T_c)/K \), \( \tilde{n} = n(T_c)/K \), \( i = 1, 2 \). Substituting the zeroth order quantities (7) in (16), one obtains
\[ \tilde{j}_{c2,f} = (3\sqrt{3}/8)(|a|/b)\tilde{f}_{12}(2 + \frac{g_{ii}}{\tilde{g}_{ii}^2} - \tilde{g}_{ii})^2 \times \left( \sqrt{2 + \tilde{g}_{ii}^2 - \tilde{g}_{ii}}^2 \right). \]
\[ \text{(17)} \]

Both contributions to the second harmonic (10) and (17) are of the second order in transparency \( \propto D^2 \), but this also contains an additional small parameter \( |\tau| = (T_c - T)/T_c \), since \( |a| = a|\tau| \). This allows to disregard (17) in studying the residual problem assumed above. However, in a number of specific cases the coupling constant \( g_{ii} \) can vanish for symmetry reason. This concerns, in particular, the asymmetric junction between identical \( d_{xy} \)-wave superconductors with exact (100) and (110) interface-to-crystal orientations on opposite sides of a smooth plane interlayer. An additional element of the point symmetry inherent in such a specific system is the reflection in the \( xz \)-plane perpendicular to the interface. Free energy should be invariant under the latter transformation, while the \( d_{xy} \)-wave order parameter on one side of the interface changes its sign and the \( d_{xz}, yz \)-wave order parameter on another side keeps its value unchanged. Then the expression containing \(|\Psi_1 - \Psi_2|^2\) in (2) is no longer invariant and, therefore, the coefficients \( g_{12}, n_{12} \) and \( n_{12} \) should vanish in the case of free energy. By contrast, the term containing \(|\Psi_1^2 - \Psi_2^2|^2\) in (2) remains unchanged under the sign reversal of one of the order parameters and, hence, the coefficient \( f_{12} \) can maintain its regular value.

In reality, the first harmonic \( \tilde{j}_{1} \) remains finite and, along with \( \tilde{j}_{c2,f} \), still represents a substantial part of the supercurrent, mainly due to interfacial imperfections such as faceting, roughness, etc. Since \( |j_{c2,f} / j_{c1}| \ll 1 \), the relation \( |j_{c2,f}| \ll |j_{c1}| \) always results in the condition \( j_{c2,f} \gg j_{c1} \), which consequently loses its importance in the special case of strongly suppressed \( g_{ii} \).

VI. NEXT ORDER TERMS IN THE BC

Let the parameters \( g_{12} \) and \( g_{ii} \) \((i = 1, 2)\) be independent of \( T \) near \( T_c \). Since \( g_{12}, g_{ii} \propto \xi(T) \), then close to \( T_c \) one will get \( |g_{12}| \gg 1 \) and/or \( |g_{ii}| \gg 1 \) due to large values of \( \xi(T) \). However, the coupling constants \( |g_{12}| \) and \( |g_{ii}| \) can themselves be very small and the temperature range with large \( |g_{12}| \) and/or \( |g_{ii}| \) be too narrow. While the condition \( |g_{12}| \ll 1 \), resulting in the tunneling behavior, is assumed throughout this paper, the range of variations of \( g_{ii} \), defined by the strength of interfacial proximity effects, is quite wide. It contains, for instance, small values of \( |g_{ii}| \). For this reason numerical coefficients of the order of unity, originating from (3), have been kept in (6)-(11) on an equal footing with \( \tilde{g}_{ii}^2 \). However, the additional terms of the next order of smallness, which come from the BC, can be comparable with the terms referred to above and should generally be taken into account.

To clarify the point, let's represent the BC schematically as \( (df_i/dx) \approx \tilde{A}_{i,0} + (|a|/b)\tilde{A}_{i,1} \) \((i = 1, 2)\). Here \( \tilde{A}_{i,0} = A_{i,0}(T_c)/K \) is linear in the order parameters and coincides with the right hand side of (4). The correction \( \tilde{A}_{i,1} \approx \tilde{A}_{i,1}(T_c)/K \) appears in the BC both from the quartic and biquadratic terms of the interface free energy (2) and from the weak temperature dependence of the GL coefficients in \( A_{i,0} \). Therefore, in addition, it involves the temperature derivatives of the coefficients. As (3) \((|df_i/dx|^2) \approx \tilde{A}_{i,0}^2 + 2(|a|/b)\tilde{A}_{i,0} \tilde{A}_{i,1} \approx \tilde{A}_{i,0}^2 \).

The corresponding terms should, in general, be taken into account for the quantitative description of the Josephson current. However, as the main contribution to (3) \((|df_i/dx|^2) \) is quadratic and the correction is linear in \( A_{i,0} \), for sufficiently large \( |A_{i,0}| \) the correction is negligibly small as compared to \( \tilde{A}_{i,0}^2 \). For sufficiently small \( |A_{i,0}| \) the correction can now also be disregarded as compared to the coefficients of the order of unity in (3).

In tunnel junctions, the basic correction of the given origin is described by the crossed product \( 4g_{ii}h_{ii}/(Kb) \). In particular, in the zeroth approximation in the transparency the order parameters are
\[ f_{i0}^{(0)} = \left[ 1 + \tilde{g}_{ii}^2 + \sqrt{(1 + \tilde{g}_{ii}^2)^2 - L_i} \right]^{-1}, \]
\[ \text{(18)} \]

where \( L_i = 1 - (4g_{ii}h_{ii})/(Kb) \) and \( g_{ii}, h_{ii} > 0 \). The quantities \( \tilde{g}_{ii}^2 = g_{ii}^2/K|a| \) are applied here and below to involve \( g_{ii}^2 \) in the expanded form \( g_{ii}^2 \approx n_{ii}^2 + 2\eta_{ii}d_{ii}(dg_{ii}/d\chi) \), where weak temperature dependence of \( g_{ii} \) near \( T_c \) is taken into account in linear in \( \tau \) approximation.

The linear in \( \tilde{g}_{ii} \) first harmonic is obtained by substituting (18) in (5). Calculating also the second harmonic, one obtains the modified relation between the second and the first harmonics:
\[ \tilde{j}_{c2} = \frac{\tilde{g}_{ii}^2}{3\sqrt{3}} \sum_{i=1}^{2} \left[ 1 + \tilde{g}_{ii}^2 + \sqrt{(1 + \tilde{g}_{ii}^2)^2 - L_i} \right]. \]
\[ \text{(19)} \]

In disregarding the term \((4g_{ii}h_{ii})/(Kb)\), Eqs. (18) and (19) are reduced to the previous ones, Eqs. (7) and (11). Since the two parameters \( g_{ii} = g_{ii}(T_c)/K \) and \( 4g_{ii}h_{ii}/(Kb) \) are independent of each other, the conditions \( g_{ii} \ll 1 \) do not generally exclude the special case \( 4g_{ii}h_{ii}/(Kb) \ll 1 \). Then quadratic in \( h_{ii} \) corrections can also be noticeable. However, for sufficiently small \( |g_{ii}| \) the
opposite conditions $(4|\tilde{g}_{ii}|h_{ii}/(Kb))^{1/2} < 1$ occur and allow to disregard all the corresponding terms.

For large $\tilde{g}_{ii}$ the term $(4g_{ii}h_{ii})/(Kb)$ becomes negligibly small in (19), when the temperature dependent condition $\xi(T)\tilde{g}_{ii}^2 >> 4h_{ii}/b$, in keeping with $\tilde{g}_{ii} \gg 1$, is valid. Also, for one and the same $g_{ii}$, the right hand side in (19) is always larger than that in (11), if $(g_{ii}h_{ii})/(Kb) > 0$. Therefore, the modified formulas do not alter the main statement of this paper.

In conclusion, a test for identification of a pronounced interfacial pair breaking in Josephson tunnel junctions has been proposed and theoretically verified in this paper, based on Eqs. (9)-(11) and (19) obtained within the self-consistent theory of the Josephson current. The main statement is that the condition $j_{c2}d_{fp} \gg j_{c1}^2$ indicates to a strong interfacial pair breaking at least on one side of the interface, if the first and the second harmonics satisfy the conventional relation $j_{c2} \ll |j_{c1}|$.

Appendix: Order parameter profiles near impenetrable boundaries

The GL theory allows a detailed description of the spatial profiles of the order parameters near impenetrable boundaries. Here the boundaries, which either suppress or enhance the superconductivity in their vicinities, are considered jointly.

In the case in question the supercurrent vanishes and $f_\infty = 1$. Then Eq. (3) reduces to

$$
\left( \frac{df(\tilde{x})}{d\tilde{x}} \right)^2 = \frac{1}{2} \left[ 1 - f^2(\tilde{x}) \right]^2. \tag{A.1}
$$

The solution of (A.1), which is relevant to the order parameter near a pair breaking surface at $x = 0$ satisfies the condition $f < 1$ throughout the halfspace $x > 0$ and takes the form (see, e.g., Ref. 42)

$$
f_{pb}(\tilde{x}) = \tanh \left( \frac{\tilde{x} + \tilde{x}_0}{\sqrt{2}} \right). \tag{A.2}
$$

The parameter $\tilde{x}_0 > 0$ together with the associated order parameter value on the surface should be determined from the boundary conditions.

The expression for the order parameter in superconducting half space with the pair producing surface directly follows from (A.2), since for each $f(\tilde{x})$, which meets (A.1), the function $1/f(\tilde{x})$ satisfies the same equation (A.1). This results in the following solution

$$
f_{pp}(\tilde{x}) = \coth \left( \frac{\tilde{x} + \tilde{x}_0}{\sqrt{2}} \right), \tag{A.3}
$$

for which the condition $f_{pp} > 1$ holds throughout the half space $x > 0$.

The order parameter $f_0$, taken on the surface and described by (7), can be alternatively determined by minimizing full free energy (1) and (2) with the solutions (A.2) or (A.3). Explicit integration in (1) with (A.2) or (A.3) results in the part of the bulk free energy modified by the boundary. Retaining only the quadratic in the order parameter term in the surface free energy (2), one finds the full energy per unit square of an impenetrable surface

$$
\mathcal{F} = \frac{\sqrt{K}\alpha}{\sqrt{2}b} \left[ \frac{4}{3} - 2f_0 + \frac{2}{3}f_0^3 + \sqrt{2}g_0^2 \right], \tag{A.4}
$$

for both solutions. The extremum of (A.4) does result in (7) irrespective of the sign of $g$. The surface suppresses the superconducting order parameter at $g > 0$, while at $g < 0$ the superconductivity is enhanced near the surface.

It follows from (A.2) and (A.3)

$$
\frac{df_{pb}(\tilde{x})}{d\tilde{x}} = \frac{1}{\sqrt{2}} \text{sech}^2 \left( \frac{\tilde{x} + \tilde{x}_0}{\sqrt{2}} \right), \tag{A.5}
$$

$$
\frac{df_{pp}(\tilde{x})}{d\tilde{x}} = - \frac{1}{\sqrt{2}} \text{csch}^2 \left( \frac{\tilde{x} + \tilde{x}_0}{\sqrt{2}} \right). \tag{A.6}
$$

As seen from (A.5), the order parameter (A.2), which is suppressed near the boundary, satisfies not only the condition $f_{pb}(\tilde{x}) < 1$, but also the relation

$$
\frac{\left| df_{pb}(\tilde{x}) \right|}{d\tilde{x}} \leq \frac{1}{\sqrt{2}}. \tag{A.7}
$$

For the order parameter (A.3), which is enhanced near the boundary, one gets $f_{pp}(\tilde{x}) > 1$. According to (A.3) and (A.6), the smaller the parameter $x_0$, the larger both the order parameter $f_{pp,0}$ and its derivative $|df_{pp}/d\tilde{x}|_0$ taken on the boundary. A large spatial derivative $|df_{pp}/d\tilde{x}|_0$ corresponds to a small characteristic scale induced in a superconductor in the vicinity of the surface.

For $g < 0$ and $|\tilde{g}| \gg 1$ one gets from (7) and (4) $f_0 \approx \sqrt{2}g_0$ and $|df/d\tilde{x}|_0 \approx \sqrt{2}g_0^2$. Hence, the effective characteristic scale near the surface is $x_0 \sim \xi(T)/|\tilde{g}|$. For the use of the GL theory near the surface one assumes $x_0 \gg \xi_0$. This results in the condition $|\tilde{g}| \ll 1/\sqrt{\tau}$, i.e., $|\tilde{g}| \ll \sqrt{K\alpha}$.

25. The results of Ref. 26 concern only the pair breaking effects in symmetric junctions ($f_0 < 1$), though the main equation (3) also applies to $f_0 > 1$. In the corresponding particular case $g_{11} = g_{22} = g_3 > 0$ Eqs. (9) and (10) of this paper are reduced to Eq. (5) of Ref. 26. It follows from Eq. (10) that the second harmonic is positive and does not change its sign under the sign reversal of $g_{11}$.
