Abstract

Background: Sexual dysfunction is common in patients with schizophrenia, however it is poorly studied in China, especially in primary health care institutions in rural areas. We investigated the prevalence of sexual dysfunction and its correlates including quality of life (QoL), in schizophrenia patients treated in primary care in a rural area in China.

Method: By using a random numbers table, 21 small town primary care service centers (from 63 totally) were selected in the study. Data of 720 community-dwelling patients with schizophrenia in rural area with diagnoses according to DSM –IV or ICD-10 were collected by interviews. Data on socio-demographic and clinical characteristics including sexual dysfunction and quality of life (QoL) were collected using a standardized protocol and data collection procedure. Data were analyzed using chi-square tests, t-tests, U-tests, ANCOVA and multiple logistic regression as appropriate by SPSS 21.0. The level of significance was set at 0.05 (two-tailed).

Results: In this sample, sexual dysfunction was found in 71.3% of the whole sample, 82.7% of female patients and 64.5% of male patients. Multiple logistic regression analysis showed that older age (OR = 1.06, P <0.001, 95%CI: 1.04–1.09) and higher Brief Psychotic Rating Scale (negative domain) score (OR = 1.16, P = 0.01, 95%CI: 1.02–1.31) were significantly associated with sexual dysfunction. Contrary to previous findings, sexual dysfunction was not associated with quality of life after controlling for confounding variables.

Conclusions: More than 2/3 of schizophrenia patients living in a rural area complained of sexual dysfunction, which was associated with older age and more negative psychotic symptoms. Primary care physicians should pay attention to sexual dysfunction during the assessment and treatment of patients with schizophrenia in rural areas in China.

Keywords: Sexual dysfunction, Quality of life, Schizophrenia, Rural
both patients and clinicians. Due to cultural barriers, schizophrenia patients may feel uncomfortable in raising their sexual issues and clinicians may be unwilling to discuss sexual problems, fearing that it may interfere with the doctor-patient relationship [12, 17].

The relationship between sexual dysfunction and quality of life reported in previous studies has been inconsistent. One study found that patients with sexual dysfunction had significantly poorer quality of life [18]. Similarly, another study found that sexual dysfunction was related to decreased subjective quality of life in patients with schizophrenia or schizoaffective disorder [19]. However, others reported no significant difference between sexual dysfunction and self-rated or observer-rated quality of life in schizophrenia patients [12].

Due to the lack of data especially in rural areas, and previous inconsistent findings, we therefore aimed to investigate the prevalence of sexual dysfunction in patients with schizophrenia treated by primary care physicians in rural areas in China, and explore its correlates with socio-demographic and clinical factors, and quality of life.

Methods
Study design and participants
This cross-sectional study using a standard protocol and data procedure was conducted by the Guangdong Mental Health Center of Guangdong Provincial People’s Hospital, cooperating with the Third People’s Hospital of Luoding. Luoding is located in a rural and underdeveloped area, lying in the western side of Guangdong Province. The inclusion criteria were as follows: (1) meeting the diagnostic criteria of schizophrenia according to ICD – 10 via an interview by a clinical psychiatrist; (2) aged 18 years or older; (3) receiving treatment or mental health services from primary care physicians in community-based settings in Luoding; and (4) having the ability to read and understand the contents of the interview.

There are a total of 63 small town primary care services in Luoding, which is under the jurisdiction of Yunfu City. The survey sample size calculation took into account the estimated prevalence of sexual dysfunction (estimated as 40–80%), the absolute error (varying between 0.01 and 0.10), a confidence level of 95%, and the costs of data collection. The final target sample size was established at 750, which is about 30% of the total patients with schizophrenia in Luoding area. A stratified cluster was used. We randomly selected 21 small town primary care services in Luoding, using a random number table. All schizophrenic patients in the community treated in the primary health care services are registered in the Chinese National Psychiatric Management System. We tried to establish contact with all patients who are treated in the primary care services selected above by telephone at first. After explaining about the study, if the patients consented to participate, 3 trained psychiatrists went to the local primary health care institutions to make an interview with patients.

Ethical consideration
Ethical clearance was obtained from the Ethics Committees of Guangdong Provincial People’s Hospital. After measuring the capacity of the patient to give consent, the trained interviews explained to each of the competent participant about the purpose, importance and confidentiality of the information gathered before we began the interview. Participants were also informed that they will not get any benefit because of participation in the study and no harm on them. Their willingness to be involved in the study was asked and written consent was obtained. Collectors followed the code of ethics and kept the participants’ privacy.

Assessments
A standard research data form was used in the study by the researchers. Information on age, gender, education status, marital status, current drinking/smoking, age of illness onset, BMI, severe physical conditions, and family psychiatric history were collected. In addition, the use of medication including the first-generation antipsychotics (FGAs) and second-generation antipsychotics (SGAs), anticholinergics, antidepressants, and benzodiazepines were also recorded.

A common standard classification of stages in sexual response was used [20]. Sexual dysfunction was assessed by using the Arizona Sexual Experience Scale (ASEX) [21–23], which is a self-report questionnaire and has been validated in Chinese patients with schizophrenia with satisfactory psychometric properties [24]. ASEX quantifies sexual desire, arousal, vaginal lubrication/penile erection, ability to reach orgasm, and satisfaction with orgasm. The total score of ASEX is gained from the sum of the scores of five items with each score ranging from 1 to 6, so the total score range from 5 to 30. Higher scores indicate more serious sexual dysfunction. Sexual dysfunction is defined as a total score of ASEX ≥19 or any three ASEX items with a score ≥4 or any one item with an individual score ≥5 [22]. In this study, patients who have sexual partners are defined as having sexual dysfunction if their total score of ASEX ≥19. But patients without sexual partners only need to answer two items (strength of sex drive and ease of sexual arousal), and those who have any one item with a score ≥5 were defined as having sexual dysfunction.

The Brief Psychotic Rating Scale (BPRS) was used to estimate psychotic symptoms, according three domains: positive, negative, anxiety and tension [25, 26]. The Chinese version of the scale has good reliability and
validity [25]. Depressive symptoms in the last week were assessed by using Chinese version of Montgomery-Asberg Depressive Rating Scale (MADRS) [26–28] which contains 10 items. Simpson and Angus Scale of Extrapyradimal Symptoms (SAS) was used to assessed the side effects including rigidity, akinesia, tremor and salivation of medicine [29]. The quality of life (QoL) was evaluated with the Chinese version of WHOQOL-BREF [30], which covers four domains: physical, psychological, social and environment. Higher scores of the QoL Scale indicate better quality of life.

The subjects in this study were recruited from Luoding city, an underdeveloped rural area in Guangdong, China. Prior to study commencement, three interviewers underwent an inter-rater reliability exercise on the use of the assessment scales in 20 schizophrenia patients. The inter-rater reliability of the rating instruments yielded excellent agreement (intra-class correlation coefficients and kappa values > 0.95).

Statistical analysis
SPSS 21.0 for Windows was used to analyze the data. Chi-square tests were used to compare the difference of each domain of sexual dysfunction between males and females. T-test or Mann-Whitney U test was used to compare in demographic and clinical variables between patients with sexual dysfunction and without sexual dysfunction. Analysis of covariance was used to compare QoL between the above two groups after controlling for the potentially confounding effects of variables which differed significantly between groups. The association between demographic and clinical variables with sexual dysfunction was analyzed using the multiple logistic regression analysis. Sexual dysfunction was considered as the dependent variable, and the demographic and clinical characteristics which significantly differed (< 0.05) between the two groups were considered as independent variables, using 'Enter' method. Multicollinerity between independent variables was examined using variance inflation factor and correlation matrix. The level of significance was set at 0.05 (two-tailed).

Results
Socio-demographic characteristics
A total of 742 patients with schizophrenia from a rural area were enrolled in the study. Only 22 (2.0%) patients did not complete the interview or the ASEX survey. Altogether, 720 patients with schizophrenia were included in the final analysis. Among the participants 448 (62.2%) were male and 272 (37.8%) were female in gender. A total of 418 patients with schizophrenia who have sexual partners, while the other 302 patients did not have sexual partners.

Table 1 shows the frequency of different types of sexual dysfunction classified according to gender. Patients who were not sexually active only responded to two general sexual dysfunction domains. For this group, the prevalence of sexual dysfunction was 71.3% in the whole sample, 64.5% in males and 82.7% in females ($X^2 = 5.19$, $P <0.001$). For sexually active patients who completed all five sexual domains, the prevalence of sexual dysfunction was 74.1% in the whole sample, and 67.8% in males, 82.1% in females ($X^2 = 3.36$, $P = 0.001$). Female patients reported more sexual dysfunction both in terms of each sexual dysfunction domain or in the ASEX total score ($P <0.05$).

Table 2 shows the demographic and clinical characteristics in the sample who had sexual partners and in two groups separated into sexual dysfunction and non-sexual dysfunction. Among the participants with sexual partners, 310 (74.1%) had sexual dysfunction (ASEX $\geq 19$).

Clinical characteristics
Table 2 shows that there was significant difference between sexual dysfunction group and non-sexual dysfunction group in BPRS total score($T = 2.64$, $P = 0.008$), BPRS positive score ($T = 2.19$, $P = 0.029$), BPRS anxiety score ($T = 2.29$, $P = 0.02$), BPRS negative score ($T = 3.34$, $P = 0.001$).

### Table 1 Frequency of sexual dysfunction in patients with schizophrenia (Dysfunction ≥5)

| Whole Sample | Total (n = 720) | Male (n = 448) | Female (n = 272) | Statistics |
|--------------|----------------|----------------|------------------|------------|
|              | n | % | n | % | n | % | $\chi^2$ | df | $P$ |
| ASEX Items   |   |   |   |   |   |   |         |    |     |
| Strength of sex drive | 148 | 20.6 | 62 | 13.8 | 86 | 31.6 | 32.7 | 1 | <0.001 |
| Ease of sexual arousal | 151 | 21.0 | 64 | 14.2 | 87 | 31.9 | 31.9 | 1 | <0.001 |
| Patients having sexual partners |   |   |   |   |   |   |         |    |     |
| Total (n = 418) | n | % | n | % | n | % | $\chi^2$ | df | $P$ |
| Penile erection or vaginal lubrication | 93 | 22.2 | 38 | 16.3 | 55 | 29.7 | 29.7 | 1 | 0.001 |
| Ability to reach orgasm | 95 | 22.7 | 39 | 16.7 | 56 | 30.2 | 30.2 | 1 | 0.001 |
| Satisfaction of orgasm | 94 | 22.5 | 38 | 16.3 | 56 | 30.2 | 30.2 | 1 | 0.001 |

Bold values: $P < 0.05$; ASEX Arizona Sexual Experience Scale
However, there was no significant difference in side effect score ($T = 1.54$, $P = 0.124$).

**Quality of life**

Concerning the quality of life, after controlling the variables which were significantly different between sexual dysfunction and non-sexual dysfunction groups, there was no significant difference in physical ($F = 0.22$, $P = 0.63$), psychological ($F = 0.34$, $P = 0.55$), social ($F = 0.75$, $P = 0.38$) or environment ($F = 0.05$, $P = 0.82$) domain.

Table 3 shows the independent demographic and clinical correlates of sexual dysfunction. Older age (aOR = 1.06, $P < 0.001$, 95%CI: 1.04–1.09) and more BPRS negative symptoms (aOR = 1.16, $P = 0.01$, 95%CI:1.02–1.31) were significantly associated with sexual dysfunction.

Discussion

To our knowledge, this is the first study in China which investigated the frequency of sexual dysfunction and its associated factors in a sample of schizophrenia patients treated in primary care in a rural area.

The study found that the prevalence of sexual dysfunction is high in Chinese rural patients with schizophrenia, and they may need relevant intervention on this issue. Although the patients in this study treated in primary care are clinical stable, the prevalence of sexual dysfunction in patients with schizophrenia in our study is supported by some other studies in other countries. A study in Egypt on paranoid and non-paranoid schizophrenia patients reported that the prevalence of sexual dysfunction in paranoid schizophrenia patients reached 80% while the other group reached 86.7% [31]. A study conducted in Ethiopia in 2017 also reported high prevalence on sexual dysfunction in patients with schizophrenia, reaching 82.7% [32]. Contrary to these studies, the study conducted in Britain reported the prevalence of sexual dysfunction was 45% [33], nearly half of the prevalence of our study. The studies in Nigeria showed different results in different areas [34]. In another study conducted in Nigeria, the prevalence of sexual dysfunction with patients with psychotic disorder was higher in the northern region (64.3%) than in the southwestern region (40.4%) [34].

In general population, most studies have reported more common sexual dysfunction in females than in males [35, 36]. About 20–30% of men and 40–45% of women reported at least one item of sexual dysfunction [37–39]. In a previous study in India, 70% of female patients with schizophrenia reported having sexual dysfunction [40]. Our study found higher rates of total sexual dysfunction in female schizophrenia patients than male patients. But this difference in the rate of sexual dysfunction between genders is inconsistent in previous studies [11, 41, 42]. Some studies reported higher rates of sexual dysfunction in female patients [11, 34], others reported opposite results [41], while some found similar rates between genders [42].

The prevalence of sexual dysfunction was higher in females (82.7%), than in males (64.5%), which is consistent with findings reported in other studies (female 45–80% and male 30–80%) [1, 14, 17, 43]. Compared to our study conducted in the city areas of Guangdong using the same assessment tools which showed a prevalence of sexual dysfunction of 80.6% in females and 60.7% in males [44], the prevalence in the rural areas appear slightly higher than in city areas.

The discrepancies in the prevalence of sexual dysfunction in different areas and genders are due to multiple factors, including different study areas, sample size, socio-demographic factors, cultural environment (open or closed), assessment tools to assess sexual dysfunction (self-report or asked by researchers), gender preponderance, psychopathology and psychotropic medication use [14, 45]. As for the assessment tools, in a study in America, the researchers used the Global Impression of Sexual Function (GISF) to assess sexual dysfunction [46], while another study in Dallas of America used the Arizona Sexual Experience Scale (ASEX) to assess sexual dysfunction [21]. Different assessment tools may be one of the reason for the discrepancies between areas and genders. In addition, patient reports of sexual dysfunction are significantly influenced by cultural factors and social acceptance in discussing sexual issues. According to a
meta analysis, the prevalence of sexual dysfunction reported in Asia countries was lower than western counties [15]. Further, clinicians themselves may be conservative in enquiring about sexual concerns or consider sexual-related complains as insignificant in schizophrenia patients as compared to positive psychotic symptoms [17].

Our study found a negative association between age and sexual dysfunction, which was consistent with our previous study in city areas [44]. Some studies showed that older age is a risk factor for sexual dysfunction not only in general population but also in schizophrenia patients [21, 35, 36, 47]. With increasing age and chronic course of illness, schizophrenia patients may suffer physical conditions such as hypertension, diabetes and others, which may influence sexual function adversely. However, a previous study found at age was not an independent risk factor of sexual dysfunction, although age and illness duration were negatively associated with sexual dysfunction in sexual desire, arousal and satisfaction domains [48].

In this study, we also found an association between negative symptoms and sexual dysfunction. Negative symptoms are core features of schizophrenia. In a case-control study, sexual dysfunction was associated with negative symptoms [11], while another schizophrenia study from Europe showed that negative symptoms predicted decreased libido [49].

Quality of life is increasingly used to assess treatment outcome for schizophrenia patients [12, 19, 50, 51], and sexual function is an important part of QoL, which could be influenced by social-demographic characteristics [19], psychopathology [12], treatment modalities (eg, antipsychotic drugs) [52–54] and side effects [15, 55]. One study reported that patients with schizophrenia were more dissatisfied with their sex life than any other aspects of life [56]. Sexual dysfunction can reduce the medication compliance [57], which can increase the risk of the illness recurrence, re-hospitalization [58] or suicide attempts [59], and lower the quality of life [59]. However, in contrast to the results reported in Ethiopia, claiming that sexual dysfunction is highly associated with poor quality of life [32], we found no significant differences between the gender groups in any domains of QoL, which is consistent with our previous city study [44] . However, WHQoL is not specifically designed to measure the QoL for schizophrenia patients on sexual problems and only measures the QoL over last two weeks [30] rather than long term period.

The strength of this study is the sample was relatively homogeneous and was selected randomly from a rural area. However, there are several limitations in this study. Firstly, it was a cross-sectional design without control group from the general population and so the causality between sexual dysfunction and variables could not be assessed. Secondly, schizophrenia patients in this were clinically stable and living in the community and the results cannot be generalized to patients in other illness stages. Thirdly, we did not perform a follow-up sexual dysfunction assessment of the patients. Fourthly, ASEX is an evaluation tool rather than a diagnostic tool [60] and may be not sensitive enough to diagnose the sexual dysfunction.

Conclusion
In conclusion, more than 2/3 patients with schizophrenia in the rural area reported sexual dysfunction, which was associated with older age and negative psychotic symptoms, but not with quality of life. Primary care physicians should pay attention to sexual dysfunction during the assessment and treatment of patients with schizophrenia in rural areas in China.

Acknowledgments
The authors thank all the clinicians for their contribution to this study.

Authors’ contributions
FJ, CLH and NgC involved in the conception and design of the study, developed data collection tools, supervised data collection and analyzed data. YHH involved in manuscript writing. CLH, QWW, ZHH, and XC helped with the manuscript preparation. All authors read and approved the final manuscript.

Funding
The study was supported by the Medical Science and Technology Research Foundation of Guangdong Province (Grant numbers: 2018A030313816).

Availability of data and materials
The authors confirm that, for approved reasons, some access restrictions apply to the data underlying the findings. The data set contains identifying participant information, which is not suitable for public deposition. Data might be available upon request by contacting the corresponding author; however, the request must comply with confidentiality and ethics rules of the ethics committee of our institution.

Ethics approval and consent to participate
The study protocol was approved by the Ethics Committees of Guangdong Provincial People’s Hospital. Written informed consent was provided by each patient.

Consent for publication
Not applicable.

Competing interests
