Potential chiral fluorescent molecular probes based on an α,β-unsaturated ketone for anion detection

Congshu Li1, Lixia Liu1, Weitong Pan2, Yanmei Chen1, Xuefang Shang1*, Yingling Wang1, Tianyun Wang3 & Xiufang Xu4

A series of potential chiral compounds containing an α,β-unsaturated ketone was developed for anion detection. The interplay of compounds and biological momentous anions (Cl\textsuperscript{−}, H\textsubscript{2}PO\textsubscript{4}\textsuperscript{−}, I\textsuperscript{−}, AcO\textsuperscript{−}, HS\textsuperscript{−}, F\textsuperscript{−}, and Br\textsuperscript{−}) was evaluated by UV-vis experiments, fluorescence experiments, and electrochemical tests. By comparison, compound 1 had the best selectivity and compound 5 had the strongest binding ability among the five compounds. And compound 5 had the highest sensitivity to H\textsubscript{2}PO\textsubscript{4}\textsuperscript{−} among the measured anions, and it also can be applied to actual samples, the content of H\textsubscript{2}PO\textsubscript{4}\textsuperscript{−} tested in the potassium dihydrogen phosphate fertilizer solution reached above 97.5% of the marked content, and the recovery rates were within the range of 98.5–99.1%, attesting that this method was reliable for the test of H\textsubscript{2}PO\textsubscript{4}\textsuperscript{−} in fertilizer. Through HRMS titration, circular dichroism and optical rotation experiments, the probable interacted mechanism was proved that the interaction site was the C=O of the α,β-unsaturated ketone structure. In addition, the interacted mechanism was researched from the perspective of chirality. Furthermore, theoretical investigation analysis was introduced to reveal that the roles of molecular frontier orbitals in molecular interplay were determined. Therefore, this series of potential chiral compounds has potential application prospects in anion recognition.

Chirality is a universal feature in the universe, which is reflected in the emergence and evolution of life1–3. With the continuous in-depth research on molecular recognition, chiral molecular recognition has become an important topic4–6. At the same time, with the increasing attention on the safety and environmental problems with using radioactive probes and the advantages of high sensitivity and good selectivity, fluorescent probes have been widely used in molecular recognition. In view of the important role of anions (such as AcO\textsuperscript{−}, HS\textsuperscript{−}, F\textsuperscript{−}, H\textsubscript{2}PO\textsubscript{4}\textsuperscript{−} etc.) in nature, a great deal of effort has been made within the field of supramolecular chemistry to devise and synthesize receptors capable of selectively identifying anions7–10. As a consequence, the development of novel molecular probes for anion sensors has been proven to be fairly active research domain11–21. However, there are few reports on potential chiral fluorescent molecular probes used to detect anions. Therefore, it is very important to use potential chiral fluorescent molecular probes to selectively detect anions.

Normally, an α,β-unsaturated ketone is linked to fluorescent groups, which will result in weak or almost no fluorescence response of fluorescent probes due to suppression of photo-induced electronic transfer (PET). The nucleophilic additive reaction of anions with an α,β-unsaturated ketone blocks the PET process and causes fluorescence recovery. Thus, we can detect the anions that we want22,23.

In this thesis, a string of potential chiral compounds containing an α,β-unsaturated ketone structure was designed and synthesized (Scheme 1). The synthetic compounds displayed a high combination capacity for AcO\textsuperscript{−}, HS\textsuperscript{−}, F\textsuperscript{−}, H\textsubscript{2}PO\textsubscript{4}\textsuperscript{−} in the sensing of different anions by UV-vis, fluorescence, electrochemical, circular dichroism and optical rotation experiments. Fortunately, the crystal of compound 1 was also obtained, which provided the foundation for the host-guest interaction.

Results and Discussion

X-ray crystallography. The ethanol solution of compound 1 was placed so that the ethanol evaporated slowly and the single light-yellow crystal was separated. The determination of its crystal structure was carried out using X-ray diffraction analysis (see Supplementary Fig. S1). X-ray diffraction data for 1 was collected, and the structural refinement results were shown in Table S1. As shown in Fig. S2, hydrogen bonds were formed between two molecular compounds, which formed a "T" configuration. The hydrogen bonds formed were linked by O(1)-H(1)...O(2)#1. (see Supplementary Table S2 Symmetry transformations used to generate equivalent atoms: #1 −x +5/2, y +1/2, −z +1/2). Additionally, π-π stacking of different "T" configurations formed a stratified structure.

UV-vis titration. The combining capacities of probes (1–5) with anions (H₂PO₄⁻, AcO⁻, HS⁻, F⁻, Cl⁻, I⁻ and Br⁻) in DMSO solution were investigated via UV-vis spectroscopy. Results manifested that these compounds (1–5) showed different binding abilities for anions. As seen in Figs. S3a, S4, compound 1 took on two intense absorption bands at approximately 292 and 365 nm, while the remarkable absorption band gradually arose at approximately 500 nm with the gradual addition of F⁻ and H₂PO₄⁻. Simultaneously, the strengths of the absorption peaks at 292 and 365 nm decreased. A distinct isoabsorptive point was noted at 376 nm and it turned out that 1 and H₂PO₄⁻ formed a stable complex in a certain proportion. The binding of H₂PO₄⁻, AcO⁻, HS⁻, F⁻ to compound 4, and H₂PO₄⁻, AcO⁻, F⁻ and HS⁻ to 5 produced phenomena similar to that of H₂PO₄⁻ to 1 (see Fig. 1a, Supplementary Figs. S3d, S7, S8). However, the excessive addition of else anions induced only the faint changes and even could be overlooked in the UV-vis spectra. For compounds 2 with two electron-withdrawing groups (-Br), it had two peaks at 320, 360 nm. After the addition of H₂PO₄⁻, AcO⁻ and F⁻, the peak increased at 320 nm, decreased at 360 nm, and formed a new peak at 500 nm, forming isoabsorptive points at 330 and 410 nm. (see Supplementary Figs. S3b, S5). Compounds 3 with H₂PO₄⁻, AcO⁻, HS⁻, F⁻ showed the same occurrences, while the other ions showed little change (see Supplementary Figs. S3c, S6). Additionally, the absorption intensity of compound 2 (3,5-dibromosalicylaldehyde derivative) was stronger than that of compound 3 (5-bromosalicylaldehyde derivative). This was due to the fact that two -Br have more electron-withdrawing property than one -Br. The binding spectra of probes 1, 4, 5 and anion were different from that of 2, 3 due to the different substituents. In comparison, compound 5 had the largest spectral change in combination with anions among the five compounds, followed by 2, possibly because -NO₂ showed stronger electron-withdrawing property than -Br, which was conducive to nucleophilic addition, and increased the combining ability of C=C in compounds

**Figure 1.** UV-vis spectral (a) and fluorescence (b) changes of compound 5 (4 × 10⁻⁵ mol·L⁻¹) upon the addition of H₂PO₄⁻. All spectra were recorded in DMSO solution, (a) H₂PO₄⁻ : ((0–8) × 10⁻⁵ mol·L⁻¹); (b) H₂PO₄⁻ : (0–20.8) × 10⁻⁵ mol·L⁻¹), λex = 412 nm. Arrows indicated the direction of increasing anion concentration.

and ions. While the -NO₂ located in the 3-position of the salicylaldehyde was weaker than that of the 5-position of the salicylaldehyde, which may be due to steric hindrance.

Detection limit. As compound 5 had the strongest binding ability, so taking it for example, the linear relationship between compound 5 and H₂PO₄⁻, F⁻, HS⁻, AcO⁻ in DMSO solution was determined by UV-vis titration. The absorption value of compound 5 (4 × 10⁻⁶ mol·L⁻¹) at 470 nm was 0.049, the molar absorption coefficient was calculated as 31005 L·mol⁻¹·cm⁻¹. As can be seen from the Figure S13a, when the concentration of AcO⁻ varies within the range of 0–10⁻² mol·L⁻¹, the UV-vis absorption value of compound 5 had a linear relationship with the concentration of AcO⁻, and the correlation coefficient was above 0.99. The absorption value of compound 5 raised with the addition of AcO⁻, until the concentration of AcO⁻ increased to 7.36 × 10⁻³ mol·L⁻¹, the absorption value of compound 5 raised to 1.3 times²⁸, which means the detection limit of compound 5 to AcO⁻ was 7.36 × 10⁻³ mol·L⁻¹. With the same method and the same conditions, the detection limit of 5 to HS⁻ was 8 × 10⁻³ mol·L⁻¹ (see Supplementary Fig. S13b), that of F⁻ was 4.8 × 10⁻⁵ mol·L⁻¹ (see Supplementary Fig. S13c), and that of H₂PO₄⁻ was 1.2 × 10⁻⁵ mol·L⁻¹ (see Supplementary Fig. S13d). According to the above data, the order of the anions sensitivity of the compound 5 was H₂PO₄⁻ > F⁻ > HS⁻ > AcO⁻.
Electrochemical experiment. In order to further explore the synthesized compound as anion probe, compound 5 was taken as an example to conduct cyclic voltammetry study in DMSO. Saturated sodium chloride solution was used as the electrolyte solution, a platinum electrode was the assistant electrode, and a calomel electrode was the reference electrode. In addition, a glassy carbon electrode was selected as the working electrode. The scan range was $-1 \text{V}$ to $1 \text{V}$, and the scanning speed was set to $50 \text{mV} \cdot \text{s}^{-1}$. Figure 3 showed the cyclic voltammetry behavior when compound 5 interacted with $\text{H}_2\text{PO}_4^-$ at $0.8 \text{V}$, compound 5 had a weak oxidation peak, while it had an obvious oxidation peak at $0.1 \text{V}$. After adding $\text{H}_2\text{PO}_4^-$, the oxidation peak of $0.8 \text{V}$ disappeared, and there was a new reduction peak near $0.1 \text{V}$. Moreover, as the concentration of $\text{H}_2\text{PO}_4^-$ increased, the anodic peak and the cathodic peak potentials both moved in the positive direction, and the current gradually decreased. After $\text{HS}^-$ was added, the oxidation peaks disappeared and a weak reduction peak appeared at $-0.6 \text{V}$. And the current decreased gradually (see Supplementary Fig. S14a). With the addition of $\text{AcO}^-$ (see Supplementary Fig. S14b) and $\text{F}^-$ (see Supplementary Fig. S14c), the oxidation peak of $0.8 \text{V}$ disappeared, the oxidation peak at $0.1 \text{V}$ moved in a negative direction, and a new reduction peak appeared near $0.4 \text{V}$, and the peaks currents decreased with the increasing of anions concentration. The changes in the figures were explained by the formation of complexes between compound 5 and $\text{AcO}^-$, $\text{F}^-$, $\text{H}_2\text{PO}_4^-$. The oxidation peak of compound 5 at $0.8 \text{V}$ may be the characteristic peak of $\alpha,\beta$-unsaturated ketone, and the peak at $0.1 \text{V}$ may be the characteristic peak of $-\text{NO}_2$. As compound 5 reacted with $\text{AcO}^-$, $\text{F}^-$, and $\text{H}_2\text{PO}_4^-$, new redox systems were formed, the redox reaction of compound 5 gradually weakened, and the $\alpha,\beta$-unsaturated ketone system was destroyed, so the oxidation peak at $0.8 \text{V}$ disappeared. The addition of $\text{Cl}^-$, $\text{Br}^-$, and $\text{I}^-$ caused almost no change in the redox signal intensity of compound 5 (see Supplementary Fig. S14d). This indicated that there was little electrochemical reaction between $\text{Cl}^-$, $\text{Br}^-$ or $\text{I}^-$ and compound 5.

Circular dichroism. Circular dichroism is a new method for studying potential chiral and stereoscopic structures of molecules, but it is seldom used in anion detection. Therefore, compound 5 was taken as an example to verify the interaction mechanism between compound and anions from the perspective of chirality through circular dichroism experiment. As shown in Fig. 4a, in DMSO, $\text{H}_2\text{PO}_4^-$ was achiral, and thus, it had no circular...
occurred with the addition of HS\(^-\) and fluorescence experiments. The experiments confirmed the above conclusion of circular dichroism experiment. The specific reasons have been explained in the circular dichroism section. In DMSO, there were intermolecular hydrogen bonds between two molecules (see Supplementary Fig. S2), so the main form of existence was ketone. However, as methanol is a protic solvent, it is easy to form hydrogen bonds with hydroxyl groups in the compound, which destroyed the original hydrogen bonds. Therefore, the main form of existence may be enol form. So the carbonyl peak at 360 nm vanished. As a result, the interaction of compound 5 and ions had different circular dichroism spectra in methanol and DMSO. The above outcome confirmed that the action site was the C=C-C of the \(\alpha,\beta\)-unsaturated ketone structure, which verified the mechanism shown in Fig. 2b above.

Figure 4. (a) The circular dichromatic spectra of \(\text{H}_2\text{PO}_4^-\), compound 5, compound 5 toward the addition of 1, 2, 5, 10 equiv. \(\text{H}_2\text{PO}_4^-\) in DMSO (b) the change in optical rotation of compound 5 after binding with \(\text{H}_2\text{PO}_4^-\) in DMSO.

Specific rotation. Again, take the reaction of compound 5 with \(\text{H}_2\text{PO}_4^-\), we did the optical rotation experiment to verify further. In the DMSO, the value of \([\alpha]_5\) was 0.0 (0.004 mol\(\cdot\)L\(^{-1}\) in DMSO), when compound 5 was combined with \(\text{H}_2\text{PO}_4^-\), the optical rotation increased continuously. When \(\text{H}_2\text{PO}_4^-\) was added to five equiv., \([\alpha]_5\text{H}_2\text{PO}_4^-\) was 0.6 (0.004 mol\(\cdot\)L\(^{-1}\) in DMSO)(Fig. 4b). Combined with the circular dichroism spectra, this may be due to that the positive and negative peak intensities of compound 5 were almost identical and cancel each other out, so the optical rotation was 0. When \(\text{H}_2\text{PO}_4^-\) was added, only the absorption peak of carbonyl group was left, so it had optical rotation. When methanol was the solvent, the value of \([\alpha]_5\) was 0.6 (0.004 mol\(\cdot\)L\(^{-1}\) in CH\(_3\)OH). When the added \(\text{H}_2\text{PO}_4^-\) was 1:1 with compound 5, the value of \([\alpha]_5\text{H}_2\text{PO}_4^-\) was 0.5 (0.004 mol\(\cdot\)L\(^{-1}\) in CH\(_3\)OH). When the ratio was 1:5, the value of \([\alpha]_5\text{H}_2\text{PO}_4^-\) was 0.0 (0.004 mol\(\cdot\)L\(^{-1}\) in CH\(_3\)OH). The optical activity disappeared (see Supplementary Fig. S16). The reaction of compound 5 and \(\text{H}_2\text{PO}_4^-\) in methanol and DMSO had opposite results due to solvent effect. The specific reasons have been explained in the circular dichroism section. The experiments confirmed the above conclusion of circular dichroism experiment.

Theoretical investigation. In order to obtain further structural information, the calculation of compound 1 was implemented in Gaussian 03. Its geometric configuration optimization (Fig. 5a) was accomplished by density functional theory combined with the B3LYP exchange correlation function and 3–21 G basis set\(^{32}\). Comparison of bond lengths (see Supplementary Table S3) and angles (see Supplementary Table S4) between the X-ray diffraction crystal structure and theoretically optimized model structure of compound 1 shows that the two data sets were basically consistent. The differences in the data may be caused by the fact that most optimizations were obtained under the gas phase conditions, and the difference in the base group and method used for calculation could be neglected. Therefore, this manifested the veracity of the theoretical method\(^{33,34}\). Meanwhile, we could know that 1 had no intramolecular hydrogen bonds. The literature\(^{35,36}\) stated clearly that intramolecular hydrogen bonding and electron-withdrawing group can heighten the anion binding ability. Therefore, this could explain why compound 1 had a very weak anionic binding capacity, which also could be proven by the UV-vis and fluorescence experiments.

\[\text{H}_2\text{PO}_4^- + \text{C}_5 \rightarrow \text{E}_5 \]
In addition, Gaussian 03 not only optimized the computational structure of compound 1 but also obtained its molecular frontier orbitals (Fig. 5b). Its lowest unoccupied molecular (LUMO) level and highest occupied molecular (HOMO) level made it possible for electron transition. For compound 1, the density in the HOMO orbital was primarily concentrated in the salicylaldehyde part; nevertheless, the electron density in the LUMO was distributed throughout the whole molecule. Thus, the change caused by the combination of host and guest in the UV-vis spectra can be explained by the electron transition of the HOMO.

**Application in sample.** Fluorescent probes were applied to real samples. Under the optimal conditions, taking the concentration range of 0–1.0 mg·mL\(^{-1}\) of H\(_2\)PO\(_4\)\(^-\) as an example, the UV-vis absorption spectrum of compound 5 was linearly correlated with H\(_2\)PO\(_4\)\(^-\)’s concentration (see Supplementary Fig. S17), and the correlation coefficient was 0.9945. The linear regression equation was \(A = 0.1541C (\text{mg·mL}^{-1}) + 0.2801 (n = 8)\). The 2.0 g potassium dihydrogen phosphate fertilizer (main content was 1.96 g) was dissolved in 50 mL DMSO and the precipitation was filtered out. The filtrate was then diluted to a main content of 0.392 mg·mL\(^{-1}\). The measured results using the above methods were shown in Table S5. Through the three measurements, the content of H\(_2\)PO\(_4\)\(^-\) tested in the fertilizer solution reached above 97.5% of the marked content. It can be seen that there was no significant difference between the content of marker and the result obtained by this method. Recovery experiments were performed on each analyzed samples by adding 0.5 mg·mL\(^{-1}\) of H\(_2\)PO\(_4\)\(^-\) standard. As shown in the Table S5, the recovery rates were within the range of 98.5–99.1%, attesting that this method was reliable for the test of H\(_2\)PO\(_4\)\(^-\) in fertilizer. The results demonstrated the applicability of the probe to actual samples.

**Methods**

The vast majority of raw materials were gained commercially, and all reagents and solvents were analytical reagents. HS\(^-\) was from NaHS, and other anions used were from the tetrabutylammonium salts purchased from Aladdin (Shanghai, People’s Republic of China) and did not need to be purified. The solvent dimethyl sulfoxide (DMSO) was gained by reduced pressure distillation after drying by Ca\(_2\)H. \(^1\)H-NMR information was obtained by a Unity Plus–400 MHz spectrometer (Bruker, Massachusetts, USA). C, H, and N elements were analyzed by a Vario-EL elemental analyzer (Elementar, Philadelphia, PA, USA). Electrospray Ionization with High-Resolution Mass Spectrometry (HRMS (ESI)) was achieved using a Mariner apparatus (Bruker, Massachusetts, USA). At 298 K, an Eclipse fluorescence spectrophotometer (Agilent, State of California, USA) was used for fluorescence experiments; circular dichroism data was measured through a Chirascan (Applied Photophysics, Surrey, UK); an UV2600 UV-vis spectrophotometer (Shimadzu, Kyoto, Japan) was used to perform UV-vis titration. A VersaSTAT 3 Potentiostat Galvanostat (Princeton Applied Research (Ametek), New Jersey, USA) was used for the electrochemical experiments. The binding constants (\(K_b\)) were acquired by nonlinear least squares (curve fitting)\(^3^9\). Five compounds (1–5) were synthesized in light of following procedures.

**Synthesis of compound 1:** Salicylaldehyde (4 mmol, 0.4966 g) and acetophenone (2 mmol, 0.2515 g) were added to the flask and ethanol solution (15 mL) was poured in to dissolve them. Then, the pale-yellow solution was filtered out. The filtrate was then diluted to a main content of 0.392 mg·mL\(^{-1}\) and (\(\pm\)’s concentration (see Supplementary Fig. S17), and the correlation coefficient was 0.9945. The linear regression equation was \(A = 0.1541C (\text{mg·mL}^{-1}) + 0.2801 (n = 8)\). The 2.0 g potassium dihydrogen phosphate fertilizer (main content was 1.96 g) was dissolved in 50 mL DMSO and the precipitation was filtered out. The filtrate was then diluted to a main content of 0.392 mg·mL\(^{-1}\). The measured results using the above methods were shown in Table S5. Through the three measurements, the content of H\(_2\)PO\(_4\)\(^-\) tested in the fertilizer solution reached above 97.5% of the marked content. It can be seen that there was no significant difference between the content of marker and the result obtained by this method. Recovery experiments were performed on each analyzed samples by adding 0.5 mg·mL\(^{-1}\) of H\(_2\)PO\(_4\)\(^-\) standard. As shown in the Table S5, the recovery rates were within the range of 98.5–99.1%, attesting that this method was reliable for the test of H\(_2\)PO\(_4\)\(^-\) in fertilizer. The results demonstrated the applicability of the probe to actual samples.

In addition, Gaussian 03 not only optimized the computational structure of compound 1 but also obtained its molecular frontier orbitals (Fig. 5b). Its lowest unoccupied molecular (LUMO) level and highest occupied molecular (HOMO) level made it possible for electron transition. For compound 1, the density in the HOMO orbital was primarily concentrated in the salicylaldehyde part; nevertheless, the electron density in the LUMO was distributed throughout the whole molecule. Thus, the change caused by the combination of host and guest in the UV-vis spectra can be explained by the electron transition of the HOMO.

Conclusion
In summary, we developed five potential chiral molecular probes with “OFF-ON” fluorescence response for AcO−, HS−, F−, H_{2}PO_{4}− detection. In addition, from HRMS and chiral means indicated that the binding site of the probe to the anion was on the α,β-unsaturated ketone structure. By comparison, compound 1 had the best selectivity and compound 5 had the strongest binding ability among the five compounds. And compound 5 had the highest sensitivity to H_{2}PO_{4}− among the measured anions, and it also can be applied to actual samples.

**Acknowledgements**

This work was supported by the Fund of Science & Technology Innovation Talents in Universities of Henan Province (15HASTIT039), Fluorescence Probe and Biomedical Detection Research Team of Xinxiang City (CXTD16001), Scientific and Technological Research Projects of Henan Province (182102311124), the Natural Science Foundation of Henan Province (182300410118), the Graduate Scientific Research Innovation Support Project of Xinxian Medical University (YJSCX201840Y).

**Author contributions**

X.S., Y.W., T.W., X.X. directed the work. C.L. and L.L. conceived the idea and designed the experiments. C.L., W.P. and Y.C. performed the synthesis and spectral determination. X.X. completed the theoretical investigation. C.L. wrote the manuscript. All authors reviewed the manuscript.
