Quasi-local photon surfaces in general spherically symmetric spacetimes

Li-Ming Cao, Yong Song

Abstract Based on the geometry of the codimension-2 surface in general spherically symmetric spacetime, we give a quasi-local definition of a photon sphere as well as a photon surface. This new definition is the generalization of the one provided by Claudel, Virbhadra, and Ellis but without referencing any umbilical hypersurface in the spacetime. The new definition effectively excludes the photon surface in spacetime without gravity. The application of the definition to the Lemaître–Tolman–Bondi (LTB) model of gravitational collapse reduces to a second order differential equation problem. We find that the energy balance on the boundary of the dust ball can provide one of the appropriate boundary conditions to this equation. Based on this crucial investigation, we find an analytic photon surface solution in the Oppenheimer–Snyder (OS) model and reasonable numerical solutions for the marginally bounded collapse in the LTB model. Interestingly, in the OS model, we find that the time difference between the occurrence of the photon surface and the event horizon is mainly determined by the total mass of the system but not the size or the strength of the gravitational field of the system.

1 Introduction

Black holes are significant objects in our universe, and they had been predicted in general relativity a long time ago. The confirmation of the existence of a black hole is important in both the classical and quantum levels of gravity. In the Milky Way, there are about 100–400 billion stars and approximately 1.5 trillion Solar masses. It believes that there is at least one supermassive black hole at the Milky Way center. To identify the existence of a black hole, we should observe its event horizon directly. However, in principle, the observation of the event horizon is impossible due to the infinite redshift of the signal. What we are observing is that the message comes from the matter near and outside the event horizon. The first image of a black hole at the center of the M87 galaxy taken by Event Horizon Telescope has published this year [1–6]. A shadow can be found clearly in the photo, and it is called a black hole shadow.

Up to date, there are many studies on the black hole shadow and photon sphere (see [7,8]). Roughly speaking, these studies can be put into two classes. In the first approach, by solving the null geodesic equations, we can get the photon spheres or the photon surfaces of some static spacetimes [9–11] and dynamical spacetimes with spherical symmetries [12]. For some stationary spacetimes, this method is also valid. For example, one can get the photon region around the rotating black holes by solving the null geodesic equations [13–16]. However, there are some practical problems in this traditional study of a photon sphere: (i) the systems which have been studied have enough symmetries (for example, the existence of a Killing tensor) to grantee the separability of the geodesic equations [7]. These are impossible for the black holes in reality or our universe. (ii) This kind of study depends on the information at the infinity of the spacetime. This dependence means that we have to know the metric of the full spacetime, especially the future infinity of spacetime. Without additional assumptions, this is certainly impossible. These problems inspire people to define a photon sphere or a photon surface in a different way. The second approach, i.e., the so-called quasi-local definition has drawn some attention these years. The first definition is given by Claudel et al. [17]. They define a photon surface in a general spacetime as a timelike (or a null) umbilical hypersurface. Based on this definition, the photon surfaces in general spherically symmetric spacetimes have been studied. However, there are some obvious problems in this definition: (i) the definition allows that spacetime, which in the absence of gravity, exists a photon surface, such as an arbitrary null hypersurface or a timelike hyperbolic surface in Minkowski...
space-time. (ii) The umbilical condition, i.e., the shear tensor of a hypersurface is vanishing, is too restrictive. This condition makes their definition does not work in an axisymmetric stationary spacetime.

In this paper, we ask and discuss some fundamental questions on a photon surface and the relevant astronomy observation. Firstly, a photon surface should reflect some strong gravity properties of the astronomical objects. Otherwise, the observation is meaningless. For instance, the photon surface can not be a characteristic of a black hole if the photon surface also exists in a flat spacetime. This requirement is not so strong but rules out the definition based on an umbilical hypersurface. Secondly, a photon surface should be some forerunner or foreshadow of an event horizon. For a stationary black hole, the photon surface or the photon region is indeed a succedaneum of the event horizon in the observation, and people can extract much information on the black hole from the shadow. Our question is: How about the dynamical case in which a black hole is formed by a massive star or a galaxy? Can the photon surface still tell us something about the event horizon? As a forerunner or a foreshadow, the photon surface should appear before the event horizon. How long will it take to wait for the occurrence of the event horizon? The time can not be too long. Otherwise, the role of a foreshadow is meaningless. Imagine that we are living in a very massive galaxy, and gravitational collapse is happening. One day, we observe that a photon sphere has appeared near the center of the galaxy. Does that mean that a black hole has formed? The event horizon is probably still absent (who knows), and will be born in a very long time if the density of the system is very low. Can this scene happen? Does the event horizon follow closely after the photon surface formed? To answer these questions, we have to study the photon sphere or the photon surface in some dynamical spacetimes, i.e., the spacetimes for gravitational collapse. In this paper, we focus on the spacetime with the symmetry of (codimension-2) maximally symmetric space. Based on the geometry of a codimension-2 surface of the spacetime, instead of an umbilical hypersurface, we refine the definition of a photon sphere and a photon surface given by Claudel, Virbhadra, and Ellis. As expected, in this new definition, the photon surface in spacetime without gravity is effectively ruled out. By this new definition, we study the photon surface in the model of gravitational collapse, i.e., the Oppenheimer–Snyder (OS) model for homogeneous dust and the more general model – Lemaître–Tolman–Bondi (LTB) model for inhomogeneous dust. The equation for the photon surface is a second order differential equation. To solve this equation, we have to impose two boundary conditions. The generalized Birkhoff type theorem ensures that the spacetime outside the dust ball is the Schwarzschild type, so the photon surface has to satisfy a match condition on the boundary of the dust ball. On the boundary, by considering the changing rate of the energy inside the photon sphere, we get another boundary condition. By these conditions, we find an analytic solution to the photon surface equation in the OS model, and that the time difference between the occurrence of the photon surface and event horizon is mainly determined by the total mass of the system but not the size or the strength of the gravitational field of the system. So even for a galaxy with huge size and very low density, the time between the formation of a photon surface and an event horizon is quite short. So, at least in this simple model, the observation of the photon surface is reliable for observing the event horizon. For the inhomogeneous LTB model, we only consider the case of marginally bounded collapse. By numerical calculation, we get the photon surfaces when the system collapses into a black hole or a naked singularity. This study shows: A photon surface always precedes an event horizon. An event horizon, regular or not, is always accompanied by a photon surface. So even in the case of a globally naked singularity, the photon sphere or the photon surface also exists. This suggests that the observation of a globally naked singularity might be similar to a black hole. Of course, the shadow of a globally naked singularity should be very different from the one of a black hole [18–22].

This paper is organized as follows: in Sect. 2, we will give new definitions of a photon sphere and a photon surface. In Sect. 3, based on these definitions, some results on the photon sphere will be presented for a general static spacetime. In Sect. 4, we give the evolution equations of some important quantities associated with the photon surface. In Sect. 5, the photon surfaces in the OS model and the LTB model will be studied, and the analytic solution in the OS model and the numerical results for the LTB model will be shown there. Section 6 is devoted to the conclusion and discussion.

Convention of this paper: We choose the system of geometrized unit, i.e., set $G = c = 1$. And in $d$-dimensional spacetime, we choose the signature of $(- , + , \ldots , +)$ with $(d - 1)$ positive signs. The abstract index formalism has been used to clarify some formulas or calculations. The curvature $R_{abcd}$ of the spacetime is defined by $R_{abcd}v^d = (\nabla_a \nabla_b - \nabla_b \nabla_a)v_c$ for an arbitray tangent vector field $v^a$ [23].

2 The definition of a photon sphere and a photon surface

The metric of a spacetime $(M, g)$ with the symmetry of a codimension-2 maximally symmetric space can be expressed as

$$g = h_{AB}(y)dy^Ady^B + r^2(y)\gamma_{ij}(z)dz^idz^j, \quad (2.1)$$

where $A = 1, 2$, and $i = 1, \ldots , d - 2$, and $\gamma_{ij}dz^idz^j$ is the metric of the codimension-2 maximally symmetric space.
Definition 1 Consider a spacetime \((\mathcal{M}, g_{ab})\) which is locally the warped product of a 2-dimensional Lorentz manifold \((M, h_{ab})\) and a \((d-2)\)-dimensional constant curvature space \((K, γ_{ab})\), i.e., the metric \(g_{ab}\) can be decomposed as Eq. (2.1), and \(h_{ab}\) can be expressed by the orthogonal frame \([u, v]\) as Eq. (2.3), where \([u, v]\) have the form as Eq. (2.4). This means \(\mathcal{M}\) has a locally smooth embedding \(ϕ : K × [0, ε) × [0, δ) → \mathcal{M}\), where \(ε\) and \(δ\) are small real numbers. We choose parameters \(ξ \in [0, ε)\) and \(η \in [0, δ)\). Then, \(Σ_ξ\) and \(Σ_η\), which are defined by \([u, v]\) respectively, are foliations of \(\mathcal{M}\). The intersection of \(Σ_ξ\) and \(Σ_η\) with some constant \(ξ\) and \(η\) gives a codimension-2 surface \(K\). Then, a \(Σ_ξ\) is a patch of photon surface if on each leave \(K\), we have

\[
D_A \left( \frac{v^A}{r} \right) = 0 , \quad (2.5)
\]

and

\[
u^B DB DA \left( \frac{v^A}{r} \right) = 0 , \quad (2.6)
\]

and

\[
v^B DB DA \left( \frac{v^A}{r} \right) ≠ 0 , \quad (2.7)
\]

where \(D_A\) is the covariant derivative (along the natural basis \(\partial/∂y^A\)) which is compatible with the metric \(h\) of \((M, h)\). Each leaf \(K\) of \(Σ_ξ\) is called a photon sphere.

Definition 2 A photon sphere is called outer if \(v^B DB DA \left( \frac{v^A}{r} \right) < 0\), and inner if \(v^B DB DA \left( \frac{v^A}{r} \right) > 0\).

Here, we have assumed that \(v\) is out pointing. Roughly speaking, the out pointing requirement refers to a direction from the center of the system to infinity. This definition provides a simple classification of photon spheres.

Definition 3 An outer (inner) photon surface is a timelike hypersurface foliated by the outer (inner) photon spheres.

To understand these three definitions, we give some remarks:

(i) It should be noted here that \([u, v]\) are the normal vectors of \(K\) (actually the image of \(K\) under the embedding \(ϕ\)), and usually do not form the holonomic basis (coordinate basis or natural basis) of the normal space of \(K\). This of course implies they do not satisfy the commutation relation \([u, v] = 0\) in general. For general spherically symmetric spacetimes, the shift vectors can be set to be vanishing, then, \([u, v]\) and \([∂/∂ξ, ∂/∂η]\) have the relation that

\[
\left( \frac{∂}{∂ξ} \right)^a = N_\nu u^a , \quad \left( \frac{∂}{∂η} \right)^a = N_\nu v^a , \quad (2.8)
\]

where \([∂/∂ξ, ∂/∂η]\) are the coordinate basis, and \([N_\nu, N_\nu]\) are the so-called lapse functions \([26, 27]\).
is preserved along \( u^a \), because of the spherical symmetry, it is equivalent to that Eq. (2.5) is preserved along the evolution vector \( (\partial / \partial \xi)^a \).

(ii) Since \( D_A v^A = v_A (u^B D_B u^A) \), it is not hard to find that the first equation in the above definition can be written as

\[
v_A (u^B D_B u^A) = \frac{v^A D_A r}{r} = \frac{\theta^{(v)}}{d - 2}, \tag{2.9}
\]

where \( \theta^{(v)} \) is the expansion of the codimension-2 surface along the \( v \) direction. At a glance, this condition suggests that the expansion \( \theta^{(v)} \) is equal to \( (d - 2) \) times of the acceleration of the observer with velocity \( u \) along the direction \( v \). A more profound understanding can be found as follows. An arbitrary light ray in the spacetime travels along a null geodesic equation. Assume the wave vector can be expressed as

\[
k^a = k^A \left( \frac{\partial}{\partial y^A} \right)^a + k^l \left( \frac{\partial}{\partial z^l} \right)^a, \tag{2.10}
\]

then \( k_\alpha k^\alpha = 0 \) implies

\[
k_A k^A = -r^2 k_i k^i \leq 0. \tag{2.11}
\]

For the observer with velocity \( u^a = u^A (\partial / \partial y^A)^a \) on the codimension-2 surface, we assume he (she) gets measurement results that \( k^a v_a = 0 \) and \( k^b \nabla_b (k^a v_a) = 0 \), i.e., the light does not travel along the \( v \) direction. \( k_a v^a = 0 \) tells us \( k_A v^A = 0 \). Combining Eq. (2.11), we have

\[
k^b \nabla_b (k^a v_a) = k^A k^B D_A v_B - \frac{v^A D_A r}{r} k^B k^B
\]

\[
+ (k^i \partial_i v^A) k_A = 0. \tag{2.12}
\]

Since

\[
D_A v_B = -u_A u_B (D_C v^C) - v_A u_B D_C v^C D_C v_D, \nonumber
\]

and \( \partial_i v^B = 0 \), we find

\[
k^b \nabla_b (k^a v_a) = -(k_A v^A)^2 (D_C v^C) - (k_A v^A)(k_B u^B)
\]

\[
\times (b_C u^C) + k^B k^B \left( D_A v^A - \frac{v^A D_A r}{r} \right) = 0, \tag{2.13}
\]

where \( b^A = v^B D_B v^A \). Because \( k_A v^A = 0 \) and \( k^B k^B < 0 \), then we get Eq. (2.5). So the physical meaning of Eq. (2.5) is that the light travels on the codimension-2 surface.

(iii) Here, we have imposed a condition \( v^B D_B D_A (v^A / r) \neq 0 \) on the codimension-2 surface. This is equivalent to say that \( (2.5) \) can not be held in the neighborhood of the codimension-2 surface. Otherwise, Eq. (2.5) can not be used to characterize the strong gravity or inhomogeneity around the codimension-2 surface. In Definition 2, we have borrowed the idea from the definition of a quasi-local horizon. Mimic the outer marginal trapped surface, if the condition \( v^B D_B D_A (v^A / r) < 0 \) holds, the photon sphere is called outer. Actually, from the analysis in (i), this implies that \( k_a v^a \) tends to decrease along the direction \( v \). This can be understood as follows: When \( v^B D_B D_A (v^A / r) < 0 \), intuitively, one can imagine that \( D_A (v^A / r) \) is positive inside (and near) the photon sphere and turns to negative in the region outside (and near) the photon sphere. On the other hand, in the region very near the photon sphere, the sign of \( k^b \nabla_b (k^a v_a) \) is mainly determined by the last term in the right hand side of the first equality in Eq. (2.13).

So \( k^b \nabla_b (k^a v_a) \) is negative inside (and very near) the photon sphere. This means that the light feels some force and tries to travel along the inverse direction of \( v \). Similarly, one can use this idea to understand the definition of the inner photon spheres. In the cases of \( v^B D_B D_A (v^A / r) = 0 \), the photon sphere is degenerate, and we do not regard it as a photon sphere anymore.

(iv) The above discussions are focusing on a photon sphere. Here, we give some discussions on the codimension-1 object – a photon surface. The role playing by a photon surface is similar to a trapping horizon. After choosing a null frame, one can solve equation \( \theta^{(f)} = 0 \) and get the future trapping horizon. Furthermore, since \( \theta^{(f)} = 0 \) is a first order differential equation, one can get the position of the horizon once a boundary condition imposed. However, for a photon surface, the situation is quite different.

From Eq. (2.9), we know that Eq. (2.5) is a second order differential equation. In some sense, the second order differential equation is equivalent to a system of differential equations which includes two first order equations. Intuitively, one of the equations can be viewed as the definition of velocity \( (u^A \) here), and another equation describes the evolution of the velocity. Combining these two first order equations will determine the position of the photon surface and the orthogonal frame.

To solve the second order differential equation, firstly, one has to impose two boundary conditions. These conditions are not arbitrary and have to satisfy some physical requirements. This point will be discussed in the following sections. In principle, we do not know the orthogonal frame \( \{u, v\} \) in advance, and the two scalar equations (2.5) and (2.6) will determine the equation of the photon surface and the orthogonal frame. Then,
by giving appropriate boundary conditions, we can get the solution of the photon surface. Finally, we have to check whether the solution satisfies the condition (2.7) or not. As an example, one can see Eqs. (3.28)–(3.30) in the next section. This is a little bit different from the marginally trapped surface where the definition is independent of the gauge transformation (local Lorentz boost) of the null frame (local Lorentz boost). In this sense, the definition here is not so quasi-local as the marginally trapped surface. In the case where timelike Killing vector fields are presented, the situation is quite simple. In fact, the orthogonal frame can be obtained by symmetry without solving the above differential equation.

(v) Our definition is based on a codimension-2 surface, and the photon surface is foliated by the codimension-2 surfaces. This is different from the definition given by Claudel, Virbhadra and Ellis which is based on the umbilical hypersurface. By giving more constraints on the geometry of the codimension-2 surface, we exclude the photon surface in spacetime without gravity which is allowed in the definition of Claudel, Virbhadra and Ellis.

3 Static spacetimes

In this section, we check the definitions in general static cases. Firstly let us consider the Killing vectors in spacetime.

Consider a Killing vector field $\xi^A$ of the spacetime $(\mathcal{M}, g)$ is normal to the $(d-2)$ dimensional space (with radius $r$) everywhere. In the coordinate system $\{y^A, z^i\}$, generally, $\xi$ can be expanded as

$$\xi = \xi^A(y, z) \frac{\partial}{\partial y^A} + \xi^i(y, z) \frac{\partial}{\partial z^i}. \quad (3.1)$$

Since $\xi$ is normal to the codimension-2 space covered by the coordinates $z^i$, we have $\xi^i = 0$. So, we get

$$\xi = \xi^A(y, z) \frac{\partial}{\partial y^A}. \quad (3.2)$$

From the Killing equation, we have

$$D_A \xi_B + D_B \xi_A = 0, \quad (3.3)$$

and

$$\xi^A D_A r = 0, \quad (3.4)$$

$$\partial_r \xi_A = 0 \quad (3.5)$$

where we have used the fact that Christoffel symbols satisfy $\Gamma^A_{BC} [g] = \Gamma^A_{BC} [h]$, and $\Gamma^A_{ij} [g] = -r D_A Y_{ij}$.

If $r$ is not a constant, in the untrapped region or trapped region of the spacetime, from Eq. (3.4), $\xi^A$ has to be proportional to $\epsilon^{AB} D_B r$, where $\epsilon_{AB}$ is the components of the Levi-Civita tensor of the two dimensional Lorentz manifold $(\mathcal{M}, h)$.

If $(\mathcal{M}, g)$ is static, assume the Killing vector field has the form

$$\xi^A = -e^{-\sigma} \epsilon^{AB} D_B r, \quad (3.6)$$

in the untrapped region of the spacetime, we can get $\{u, v\}$ is the orthogonal frame given by

$$u^A = \bar{u}^A = -e^{-\sigma} \frac{D_B r}{\|D r\|}, \quad v^A = \bar{v}^A = \frac{D_A r}{\|D r\|}. \quad (3.7)$$

where $\|D r\|^2 = D_A r D^A r > 0$. The Eq. (2.6) is trivially satisfied because that $u^A$ is proportional to $\xi^A$. Then, the position of the photon sphere is determined by Eqs. (2.5) and (2.6) is trivially satisfied.

Substitute Eq. (3.7) into Eq. (2.5), it is easy to find that the position of the photon sphere is determined by the following equation

$$r (D_A D_B r - \Box r h_{AB}) D^A r D^B r + (D C r D^C r)^2 = 0. \quad (3.8)$$

This equation has another form. Contracting the Killing equation (3.3) with $D^A r$ and $K^A = -\epsilon^{AB} D_B r$, we have

$$\left(D_A D_B r - \frac{1}{2} \Box r h_{AB}\right) D^A r D^B r = \frac{1}{2} (D^A r D_A \sigma) (D_B r D^B r). \quad (3.9)$$

where $\sigma$ is defined in Eq. (3.6). Substituting Eq. (3.9) into Eq. (3.8), we get another form,

$$D^A r D_A \sigma - \Box r + \frac{2 \|D r\|^2}{r} = 0. \quad (3.10)$$

Here, we have used the fact that $D_A r D^A r > 0$ in the untrapped region.

Contracting the Killing equation (3.3) with $h^{AB}$ and considering Eq. (3.6), we get $K^A D_A \sigma = 0$. Contracting the Killing equation (3.3) with two $D^A r$, we have

$$K^A D_A D_B r D^B r = 0. \quad (3.11)$$

By using this relation and Eq. (3.9), we find

$$D_A D_B r D^B r = \frac{1}{2} (\Box r + D C r D^C \sigma) D_A r. \quad (3.12)$$

Similarly, we have

$$D_A D_B r K^B = \frac{1}{2} (\Box r - D C r D^C \sigma) K_A. \quad (3.13)$$

Based on the above results, we obtain

$$\left(D_A D_B r - \frac{1}{2} \Box r h_{AB}\right) (D_C r D^C r) = \frac{1}{2} (D_C r D^C \sigma) (D_A r D_B r - K_A K_B). \quad (3.14)$$

Concretely, for a static spacetime, the metric can be put into the following form by choosing coordinates

$$ds^2 = -h(x) dt^2 + f^{-1}(x) dx^2 + r^2(x) d\xi^i d\zeta^j. \quad (3.15)$$
The Killing vector field is $\partial/\partial t$, and the function $\sigma$ in Eq. (3.10) now is given by $\ln(r_x\sqrt{f/r})$. From Eq. (3.10), it is easy to find that the position of the photon sphere is determined by

$$2r_x^2 - h_x h = 0,$$

(3.16)

where $r_x = \partial_x r$ and $h_x = \partial_x h$. The l.h.s. of the above equation is actually proportional to $D_A(v^A/r)$ in Eq. (2.5). The analysis for deriving the equation of the photon sphere with a metric of the form (3.15) is hence a slight generalization of a recent result by Cederbaum and Galloway where $h(x) = f(x)$ and the traditional definition of photon spheres is used [28–30]. We can also calculate the l.h.s of Eq. (2.7), and find that on the photon sphere we have

$$v^B D_B D_A \left(\frac{v^A}{r}\right) = \frac{f}{2r} \left[\frac{h_{xx}}{h} - 2 \left(\frac{r_x}{r}\right)^2 - \frac{r_{xx}}{r}\right],$$

(3.17)

where $h_{xx} = \partial_x \partial_x h$ and $r_{xx} = \partial_x \partial_x r$. So we can check whether the photon sphere is outer or not just by calculating the righthand side of the above equation. For example, for the Reissner–Nordström de Sitter black hole, it is easy to find that Eq. (3.16) has two solutions, i.e., two photon spheres. One can check that the photon sphere with a larger radius is outer, and the one with a small radius is inner.

It should be noted here, in the Eqs. (3.7) and (3.10), we have used a preferred frame in Eq. (3.7). This is actually not the one simply given by Eq. (3.7). Generally, we have

$$u^A = \bar{u}^A \cosh \alpha + \bar{v}^A \sinh \alpha,$$

$$v^A = \bar{u}^A \sinh \alpha + \bar{v}^A \cosh \alpha,$$

(3.18)

where $\alpha$ is a function on the spacetime. It is not hard to find that the first equation in the definition of the photon sphere, i.e., Eq. (2.5), becomes

$$(X + \bar{v}^A D_A \alpha) \tanh \alpha + (Y + \bar{u}^A D_A \alpha) = 0,$$

(3.19)

where

$$X = -\frac{K^A D_A D_B r D^B r}{\|Dr\|^2},$$

$$Y = \frac{1}{\|Dr\|^2} \left[ \left(\frac{1}{2} \Box r - \frac{\|Dr\|^2}{r}\right)\|Dr\|^2 - (D_A D_B r - \frac{1}{2} \Box r h_{AB}) D^A r D^B r \right].$$

(3.20)

In the case of static, from Eq. (3.11), we have $X = 0$, and

$$Y = \frac{1}{\|Dr\|^2} \left[ \left(\frac{1}{2} \Box r - \frac{\|Dr\|^2}{r}\right)\|Dr\|^2 - \frac{1}{2} D^C r D_C \sigma \right].$$

(3.21)

where $\sigma$ is defined as before.

Unlike $X$, the expression $Y$ is not vanishing in general. Assume that the zero set of $Y$ is given by $S \subset M$, i.e., $Y|_S = 0$, then, in the case where $S \neq \emptyset$, we find that on $S$

$$(\bar{u}^A D_A \alpha) \tanh \alpha + \bar{u}^A D_A \alpha = 0.$$

(3.22)

Obviously, Eq. (3.19) or (3.22) is satisfied when $\alpha$ is a constant in some neighborhood of $S$, and the position of the photon sphere is just given by the zero set of $Y$, i.e., $S$.

However, to determine the constant $\alpha$, we have to consider Eq. (2.6) in the definition of the photon sphere. Considering Eq. (2.6), we have

$$U + W \tanh \alpha + V \tanh^2 \alpha = 0,$$

(3.23)

where

$$V = \bar{u}^A \bar{v}^B D_A D_B \alpha - X Y + \bar{u}^A D_A X,$$

(3.24)

$$U = \bar{u}^A \bar{u}^B D_A D_B \alpha + \frac{\|Dr\|}{r} \bar{u}^A D_A \alpha - X Y + \bar{u}^A D_A Y,$$

(3.25)

$$W = 2\bar{u}^A \bar{v}^B D_A D_B \alpha + \frac{\|Dr\|}{r} \bar{u}^A D_A \alpha - X^2 - Y^2 + \bar{u}^A D_A X + \bar{u}^A D_A Y.$$

(3.26)

In the case of static, $K^A$ (and $\bar{u}^A$) is proportional to a Killing vector field, $X$ is vanishing everywhere, $Y$ is vanishing on the photon sphere, and $\alpha$ is assumed to be a constant, so we find that on the photon sphere, Eq. (3.23) becomes

$$(\bar{u}^A D_A Y) \tanh \alpha = 0.$$

(3.27)

Generally $\bar{u}^A D_A Y$ is not vanishing, so $\alpha$ must be vanishing. One can imagine that the location of the photon sphere corresponds to the points where $Y$ changes its sign along the direction of $\bar{v}$ (roughly speaking, this direction is from the center of the gravitational system to the infinity of the spacetime). So a vanishing $\bar{u}^A D_A Y$ actually does not consistent with the definition (2.7). In a conclusion, we have a consistent solution ($\alpha = 0, S$) to Eqs. (2.5) and (2.6). Probably this solution is unique; see [29–32] for details on the uniqueness of a photon sphere.

When $S = \emptyset$, i.e., $Y$ is always non-vanishing. From Eq. (3.19), $\alpha$ cannot be constant. To get $\alpha$, one has to solve this complicated differential equation. For a simple example, consider the Minkowski spacetime (in which the photon surface is allowed by the definition in [17]), Eq. (3.19) reduces to

$$(\partial_r \alpha) \tanh \alpha + \partial_r \alpha - \frac{1}{r} = 0.$$

(3.28)
It is not hard to find a solution
\[ \alpha = \text{arctanh} \left( \frac{t - t_0}{r} \right), \] (3.29)
where \( t_0 \) is a constant, and
\[
\begin{align*}
\frac{u}{r} & = \frac{r}{\sqrt{r^2 - (t - t_0)^2}} \frac{\partial}{\partial t} + \frac{t - t_0}{\sqrt{r^2 - (t - t_0)^2}} \frac{\partial}{\partial r}, \\
v & = \frac{t - t_0}{\sqrt{r^2 - (t - t_0)^2}} \frac{\partial}{\partial t} + \frac{r}{\sqrt{r^2 - (t - t_0)^2}} \frac{\partial}{\partial r}. \quad (3.30)
\end{align*}
\]
After substituting the above results, we find Eq. (2.6) or Eq. (3.23) is trivially satisfied. For arbitrary nonvanishing fixed \( t \) and \( r \), we have the \([u, v]\) orthogonal frame denoted by Eq. (3.30), and the surface is a photon sphere according to the definition. However, these photon spheres are degenerate because the condition (2.7) cannot be satisfied. Actually, we always have \( v^B D_B D_A (v^A/r) = 0 \). The condition (2.7) effectively rules out this trivial case which is in the absence of gravity.

4 Dynamical spacetimes

What we are facing is a second order differential equation and the associated boundary conditions. We assume that \( u \) can be expressed as
\[ u = u^A \frac{\partial}{\partial y^A} \frac{dy^A}{d\tau} = \frac{\partial}{\partial y^A}, \] (4.1)
where \( \tau \) is the proper time of \( u \). After substituting this expression into Eq. (2.5) or (2.9), we get a second order equation. Providing with two boundary conditions, we can get the photon surface.

Assume that the photon surface has been found, then we can get the evolution equations for some important quantities. For example, the evolution equation of \( \alpha \). In fact, Eq. (3.19) can be written as
\[ \dot{\alpha} + X \sinh \alpha + Y \cosh \alpha = 0, \] (4.2)
where, for an arbitrary scalar \( f \), \( \dot{f} = (\hat{\alpha}^A D_A f) \cos \alpha + (\hat{\alpha}^A D_A f) \sin \alpha. \) (4.3)
From Eq. (3.20) and the definition of a photon sphere, we find that Eq. (4.2) can be written as
\[ \dot{\alpha} = \frac{r}{\| \vec{D} r \|} \left( \frac{\dot{r}}{r} \right)^2 \cos \alpha + \frac{8\pi}{d - 2} q \sin \alpha \] (4.4)
where \( q = T_{AB} v^A u^B \) is the momentum of the matter field along the direction \( v \).

To get more useful results, let us consider some identities. For the spacetime with the metric (2.1), the so-called focusing equations reduce to the following simple forms (see [33, 34] and references therein)
\[
\begin{align*}
u^A D_A \theta^{(u)} &= (a \cdot v) \theta^{(u)} - G_{AB} v^A v^B \\
- \frac{1}{2} & \left[ R - d \frac{d - 1}{d - 2} \theta^{(u)} \theta^{(v)} - d \frac{d - 3}{d - 2} \theta^{(u)} \theta^{(v)} \right], \quad (4.5)
\end{align*}
\]
\[
\begin{align*}
u^A D_A \theta^{(v)} &= (a \cdot v) \theta^{(v)} - G_{AB} u^A u^B - \frac{1}{2} \theta^{(u)} \theta^{(v)}, \quad (4.6)
\end{align*}
\]
\[
\begin{align*}
u^A D_A \theta^{(u)} &= -(b \cdot u) \theta^{(u)} - G_{AB} u^A u^B \\
+ \frac{1}{2} & \left[ R - d \frac{d - 1}{d - 2} \theta^{(u)} \theta^{(v)} + d \frac{d - 3}{d - 2} \theta^{(u)} \theta^{(v)} \right]. \quad (4.8)
\end{align*}
\]
where \( G_{AB} \) is the components of Einstein tensor,
\[
\begin{align*}
a \cdot v &= v_A a^A = v_A (u^B D_B u^A), \\
b \cdot u &= u_A b^A = u_A (v^B D_B v^A). \quad (4.9)
\end{align*}
\]
The symbol \( R \) denotes the scalar curvature of the codimension-2 surface with the constant \( r \), i.e., we have
\[ R = \frac{(d - 2)(d - 3)k}{r^2}, \] (4.10)
and
\[ \theta^{(u)} = \frac{(d - 2) u^A D_A r}{r}, \quad \theta^{(v)} = \frac{(d - 2) v^A D_A r}{r}, \] (4.11)
are expansions along \( u \) and \( v \) respectively.

Based on Eq. (4.5) and the definition (2.5), for the spacetime with the metric Eq. (2.1), we can get the evolution of a photon sphere is described by the following equations \(^1\)
\[ \frac{\dot{r}_s}{r_s} - \left( \frac{r_s}{r_s} \right)^2 \frac{\dot{r}_s}{r_s} = \frac{1}{r_s^2} \left[ k - d - 1 \frac{8\pi}{\Omega^{(k)}(d - 2) r_s^{d - 3}} E_s \right] - \frac{8\pi}{d - 2} p, \] (4.12)
where \( \Omega^{(k)}(d - 2) \) is the area of the \( (d - 2) \)-surface with unit radius, \( p = T_{AB} v^A v^B \) and \( E_s \) is the restriction of the so-called mass function,
\[ E = \frac{(d - 2) \Omega^{(k)}(d - 2) r_s^{d - 3} (k - \| D r \|^2)}{16\pi} \] (4.13)
to the photon sphere, and
\[ \frac{1}{\epsilon^2} = \frac{2|\Lambda|}{(d - 1)(d - 2)}. \] (4.14)
\(^1\) Here and after, a quantity with a lower script ‘s’ represents the quantity associated with the photon sphere.
Here, we are considering Einstein gravity with the cosmological constant $\Lambda$, so the mass function $E$ has a form (4.13) in which the contribution from the cosmological constant has been included [35]. In the case of $\Lambda = 0$, $k$ takes value 1. If $\Lambda \neq 0$, $k$ might be 0 and $\pm 1$. It should be noted here: although that the definition of a photon sphere does not depend on the theory of gravity, the above Eq. (4.12) is only valid in Einstein gravity with (or without) cosmological constant. One can get similar results in other gravity theories by choosing appropriate mass functions.

Considering the definition of the mass function (4.13) and Eq. (4.12), we can easily transform Eq. (4.4) into the following form,

$$\dot{\theta} = \frac{r_s}{N_s} \left\{ \left( k - d - 1 \right) r_s^d \frac{8\pi}{d - 2} E_s - \frac{8\pi}{d - 2} p \right\} + \frac{8\pi}{d - 2} q \sin \theta,$$

where $\sin \theta = \tan \alpha$, and $N_s$ is the restriction of

$$N = \| D r \| = \left\{ k \mp r^2 \frac{2}{\ell^2} - \frac{16\pi}{(d - 2)\Omega^{(k)}_{(d-2)} r_s^{d-2}} E_s \right\}^{1/2},$$

on a photon surface.

It should be noted here that $N^2$ is always positive because we are considering the untrapped region of spacetime. This also means that $N_s$ is always a real function.

Based on Eqs. (4.5), (4.6), it is also easy to find the evolution of the mass function is determined by

$$\dot{E}_s = \Omega^{(k)}_{(d-2)} r_s^{d-2} \left( - p \dot{r}_s + q \sqrt{r_s^2 + N_s^2} \right),$$

where $q = T_{AB} A^A B^B$.

One point that should be noted here is that the above equation can be applied to an arbitrary codimension-2 surface with an arbitrary orthogonal frame $\{ u, v \}$ because that the definition (2.5) is not necessary for the reduction of the results.

At the end of this section, we give some discussion on these results.

(i) The procedure for finding the evolution equation of a photon sphere: at first, using Eq. (3.7), one can get the $\{ \bar{u}, \bar{v} \}$ orthogonal frame, then put it into Eq. (3.18) to get the $\{ u, v \}$ orthogonal frame and align the Eqs. (4.12), (4.15), and (4.17), one can get the evolution equation for the photon sphere. Actually, by using our definition, one can get the same evolution equation as in [17] for the gravitational system which is interested to us.

(ii) Equation (4.17), in some sense, is an identity. However, it provides us useful information on the boundary conditions of a photon surface equation. In some cases, the mass function $E$ is well known; for example, the mass function for the Schwarzschild spacetime is a constant, i.e., the ADM mass. When a spacetime is jointed to the Schwarzschild spacetime in a physically meaningful manner, the Eq. (4.17) implies that the change of the mass function has to be vanishing on the boundary. This gives a condition for the evolution vector $u$ on the boundary. Since $E_s$ can be understood as the total energy inside the photon sphere, so the value of $E_s$ on the boundary is a kind of energy balance condition.

(iv) In the case of vacuum, we have $p = q = 0$. Consider the generalized Birkhoff type theorem for the metric (2.1), the spacetime has to be static outside the event horizon (if it exists). With this additional symmetry, the photon sphere does not evolve. So Eq. (4.17) implies that $E_s$ is a constant, and can be expressed as (Here, we only consider the case with a negative cosmological constant, and $E_s$ now is the AMD mass of the asymptotical AdS spacetime [36].)

$$E_s = \frac{(d - 2)\Omega^{(k)}_{(d-2)} r_s^{d-3} \left( k + \frac{r_s^2}{\ell^2} \right)}{16\pi},$$

where $r_+$ is the radius of the event horizon which satisfies $N(r_+) = 0$. Equation (4.12) now tells us

$$kr_s^{d-3} = \frac{1}{2} (d - 1) r_s^{d-3} \left( k + \frac{r_s^2}{\ell^2} \right).$$

So for the AdS black hole with a flat horizon, i.e., $k = 0$, there is no photon sphere. In the case of $k = -1$, the photon sphere exists only when $r_+ < \ell$. In this case, however, the black hole has a negative mass. When $k = 1$, it is easy to find that the photon sphere always exists and has a larger radius than the one of the event horizon. It is also obvious that the photon sphere does not exist in pure AdS spacetime.

(iv) In the case of static (matter might exist), $r_s$, $E_s$, and $\alpha$ do not evolve. So Eq. (4.17) implies $q = 0$, i.e., there is no momentum cross the photon sphere. Equation (4.12)
means that the radius of the photon sphere is given by
\[
\frac{k}{r_s^2} = \frac{d-1}{d-2} \frac{8\pi}{\Omega_{(d-2)}^{(d-2)}} E_x - \frac{8\pi}{d-2} P = 0, \tag{4.20}
\]
and the location of the photon sphere depends on the specific content of the matter field. When the pressure \( P \) is not vanishing, this is a higher order algebraic equation of \( r_s \). Then the equation may have several real roots. If this situation happens, the condition (2.7) can be used to classify these photon spheres.

5 Dust collapse

As mentioned in the introduction, the study of the photon sphere or the photon surface in the gravitational collapse model is important to the astronomy observation on the event horizon. In this section, by concrete examples, we show that the occurrence of an event horizon is always accompanied by an outer photon surface, and the event horizon appears almost immediately after the photon surface in the gravitational collapse model of dust.

5.1 Photon surface equation in LTB model

Assume the matter field is dust, and the energy-momentum tensor can be written as
\[
T_{ab} = \epsilon U_a U_b , \tag{5.1}
\]
where \( U^a \) is the four velocity of the dust and \( \epsilon \) is its mass density. The comoving coordinates for this fluid are assumed to be \( \{t, x, \ldots\} \), i.e., \( U = \partial/\partial t \), then the two dimensional coordinates \( \{y^A\} \) now have a concrete selection – \( \{t, x\} \). The metric of the spacetime can also be put into the LTB form
\[
ds^2 = -dt^2 + \left[1 + \frac{\kappa(x)}{2} \right] dx^2 + r^2(t, x) d\Omega_2^2 , \tag{5.2}
\]
where \( \kappa(x) \) is the so-called specific bending energy which is a function of \( x \), and \( r_s \) denotes \( \partial r/\partial x \). Here, we only consider the cases without the cosmological constant, and the dimension of the spacetime is four. The Einstein equations reduce to [37]
\[
E_t = 0 , \quad E_x = 4\pi r^2 r_s \epsilon , \tag{5.3}
\]
and
\[
r_s^2 = \kappa + \frac{2E}{r} , \tag{5.4}
\]
where \( E \) is the Minsner–Sharp energy, and only depends on the coordinate \( x \) now \( (E_t = 0) \). One can integrate Eq. (5.4) and get an implicit solution of \( r(t, x) \). The details can be found in [38–40].

By the Definition (2.5), or from Eqs. (4.12) and (4.15), in the general LTB model, we get the equation for the photon surface (denoted by \( x = x(t) \)) (or one can use the definition given by Claudel et al. [17] to get the same result.)
\[
\ddot{x} = \frac{1 + \kappa}{rr_x} + \frac{r_t}{r} \frac{2r_t r_x}{r_x} \dot{x} \nonumber
\]
\[
- \left( \frac{r_x}{r} + \frac{r_{xx}}{r_x} - \frac{1}{2} \frac{\kappa}{1 + \kappa} \right) x^2 + \frac{r^2}{1 + \kappa} \left( \frac{r_{xt}}{r_x} - \frac{r_t}{r_x} \right) x^3 , \tag{5.5}
\]
where “…” denotes the total derivative with respect to the coordinate \( t \). By appropriate boundary conditions, we can (at least numerically) solve this second order ordinary equation and get the photon surface of the spacetimes.

In the homogeneous case, i.e., the so-called OS model, we have an analytic solution. In the case of inhomogeneous, for simplicity, we focus on the marginally bounded collapse, i.e., \( \kappa = 0 \) (see [37]). In this particular case, we have
\[
r(t, x) = \left\{ \frac{9}{2} E(x) \left[ t_0(x) - t \right]^2 \right\}^{1/3} , \tag{5.6}
\]
where \( t_0(x) \) is a function of \( x \) and represents the location of the singularity. So one has \( t \in (-\infty, t_0(x)) \) and \( x \in [0, +\infty) \). The functions, i.e., \( E(x) \) and \( t_0(x) \), are not fixed in the solution. One can choose the coordinates on the initial hypersurface such that \( t_0(x) \) can be expressed by \( E(x) \), for example, see [38]. In this paper, however, this consideration is not necessary. It is not hard to find that the so-called shell-crossing singularity will be absent when \( t_0(x) > 0 \). This condition is also assumed to be fulfilled in this paper. Substituting (5.6) into Eq. (5.5) with \( \kappa = 0 \), one can get the detailed equation for the photon surface.

5.2 Photon surface in OS model

The OS model is the first model for the dynamical formation of a black hole. In this model, the dust is homogeneous in space, and this implies that the metric is just the FLRW universe, i.e., the function \( r \) in Eq. (5.2) is given by \( r = a(t)x \), and \( \kappa = -Kx^2 \), where \( K = 0, \pm 1 \). The case of marginally bounded collapse corresponds to \( K = 0 \), and it will be discussed in the next subsection.

Here, we only consider the case with \( K = 1 \). Let \( x = \sin \chi \), the metric can be expressed as [41]
\[
ds^2 = -dt^2 + a^2(t) d\chi^2 + \sin^2 \chi d\Omega_2^2 , \tag{5.7}
\]
and the photon surface equation (5.5) now becomes
\[
\ddot{\chi} = -\frac{a\dot{a}}{a^2} + \cot \chi - a^2 \frac{\cot \chi}{a^2} \frac{\dot{\chi}^2}{a^2} , \tag{5.8}
\]
The solution to the OS system can be expressed by the so-called cycloid parameter \( \eta \in [0, \pi] \). Actually, in the FLRW
universe, \( \eta \) is just the conformal time defined by \( a d \eta = dt \).

\[
t = \frac{a_m}{2} (\eta + \sin \eta), \quad a(\eta) = \frac{a_m}{2} (1 + \cos \eta), \quad (5.9)
\]

where

\[
a_m = \sqrt{\frac{3}{2m}}, \quad r_0 = a_m \sin \chi_0.
\]

Here, \( r_0 \) denotes the initial radius of the dust ball, and \( m \) is the ADM mass of the system.

By these, we find that the photon surface equation becomes

\[
\frac{d^2 \chi}{d\eta^2} = \cot \chi \left[ 1 - \left( \frac{d \chi}{d\eta} \right)^2 \right]. \quad (5.10)
\]

This equation can be written as

\[
\frac{d^2 \Theta}{d\eta^2} + \Theta = 0, \quad (5.11)
\]

if we introduce \( \Theta = \cos \chi \). The general solution to this equation is given by

\[
\Theta = c_1 \cos \eta + c_2 \sin \eta, \quad (5.12)
\]

or

\[
\cos \chi = c_1 \cos \eta + c_2 \sin \eta, \quad (5.13)
\]

where \( c_1 \) and \( c_2 \) are two integral constants.

Now let us fix the constants \( c_1 \) and \( c_2 \). From the solution (5.9), we find that the surface of the dust ball can be expressed as

\[
r_b = \frac{r_0}{2} (1 + \cos \eta). \quad (5.14)
\]

The radius of the photon sphere is given by

\[
r_s = a \sin \chi = \frac{1}{2} a_m (1 + \cos \eta) \sin \chi, \quad (5.15)
\]

where \( \sin \chi \) is determined by Eq. (5.13).

Outside the ball, the spacetime is the standard Schwarzschild spacetime, and the radius of the photon sphere is given by \( r = 3m \). So we have \( r_s = r_b = 3m \) when the photon surface meets the boundary of the dust ball. \( r_b = 3m \) gives the time of the intersection point (we have assumed \( r_0 > 3m \))

\[
\cos \eta = -1 + \frac{6m}{r_0}, \quad (5.16)
\]

and then \( r_s = 3m \) tells us

\[
\pm \sqrt{1 - \frac{2m}{r_0}} = -c_1 \left( 1 - \frac{6m}{r_0} \right) + c_2 \sqrt{\frac{12m}{r_0} \left( 1 - \frac{3m}{r_0} \right)}, \quad (5.17)
\]

where “+” implies \( \cos \chi > 0 \), and “−” implies \( \cos \chi < 0 \).

Here, obviously, we should choose the positive branch.

Physically, on the boundary of the dust ball, we should have \( \dot{E} = 0 \), and this gives \( \tanh \alpha = \pm 1 \) from the Eq. (4.17).

From the definitions of \( u \) and \( v \) in (3.18), we have

\[
p = \epsilon \frac{(\cos \chi \sin \alpha - \dot{a} \sin \chi \cosh \alpha)^2}{\cos^2 \chi - \dot{a}^2 \sin^2 \chi}, \quad (5.18)
\]

and

\[
q = \epsilon \frac{(\cos \chi \sin \alpha - \dot{a} \sin \chi \cosh \alpha)(\cos \chi \cosh \alpha - \dot{a} \sin \sin \alpha)}{\cos^2 \chi - \dot{a}^2 \sin^2 \chi}, \quad (5.19)
\]

where \( \epsilon \) is the density of the dust measured by the comoving observer. So \( \dot{E} = 0 \) implies \( \tanh \alpha = \pm 1 \) on the boundary of the dust ball. The vector \( v \) is past pointing if we choose \( \tanh \alpha = -1 \). So we have to choose \( \tanh \alpha = 1 \) on the boundary.

On the other hand, assume the proper time for \( u \) is \( \tau \), then we have

\[
u = \frac{dt}{\dot{\tau}} \frac{\partial}{\partial \tau} + \frac{d\chi}{\dot{\tau}} \frac{\partial}{\partial \chi}, \quad (5.20)
\]

and this suggests that on the boundary

\[
\frac{d\chi}{d\eta} = \frac{\cos \chi - \dot{a} \sin \chi \tanh \alpha}{a (\cos \chi \tanh \alpha - \dot{a} \sin \chi)} = \frac{1}{\dot{a}}. \quad (5.21)
\]

By using the relation between \( \eta \) and \( t \), we find that on the boundary we have to set

\[
\frac{d\chi}{d\eta} = 1. \quad (5.22)
\]

This means that on the boundary we have

\[
\sin \chi = c_1 \sin \eta - c_2 \cos \eta, \quad (5.23)
\]

then, combining Eq. (5.13), we have

\[
c_1 = -\left( 1 - \frac{6m}{r_0} \right) \sqrt{1 - \frac{2m}{r_0}} + \sqrt{\frac{2m}{r_0} \left( 1 - \frac{3m}{r_0} \right)}, \quad (5.24)
\]

and

\[
c_2 = \left( 1 - \frac{6m}{r_0} \right) \sqrt{\frac{2m}{r_0}} + \sqrt{\frac{12m}{r_0} \left( 1 - \frac{2m}{r_0} \right) \left( 1 - \frac{3m}{r_0} \right)}. \quad (5.25)
\]

Once \( c_1 \) and \( c_2 \) are fixed, we can calculate the time that the photon surface appears. It is given by \( \sin \chi = 0 \), i.e., \( \cos \chi = 1 \). It is not hard to find that the time satisfies \( \cos \eta_s = c_1 \), and this equation has a general solution

\[
\eta_s = 2\pi n \pm \arccos(c_1). \quad (5.26)
\]
The time difference between the occurrence of the event horizon and photon surface. The limit value is \((\sqrt{6} - 8)/6 \approx 2.3409\) m

where \(n\) is an integer which should be vanishing here. The sign “\(\pm\)” is chosen to match the physical requirement of smoothness. Here, we have

\[
\eta_s = \begin{cases} 
- \arccos(c_1), & 3m \leq r \leq (18/5)m, \\
+ \arccos(c_1), & (18/5)m \leq r < \infty.
\end{cases}
\]  

The time for the occurrence of the event horizon is given by

\[
\eta_e = 2 \arccos\left(\frac{\sqrt{2m}}{r_0}\right) - \arcsin\left(\frac{\sqrt{2m}}{r_0}\right).
\]  

Some calculations show that \(\eta_e - \eta_s\) is always negative. So the photon sphere always appears before the event horizon. By substituting \(\eta_s\) and \(\eta_e\) into Eq. (5.9), we can get the time delay, denoted by \(\Delta t\), of the event horizon, see Fig. 1.

At the end of this subsection, let us check whether the solution here satisfies Definition 1. Based on the solution (5.13), the evolution vector \(u\) is given by

\[
u = \frac{1}{a} \left\{ 1 - \left( \frac{c_1 \sin \eta - c_2 \cos \eta}{\sin \chi} \right)^2 \right\}^{-1/2}
\times \left[ \frac{\partial}{\partial \eta} + \left( \frac{c_1 \sin \eta - c_2 \cos \eta}{\sin \chi} \right) \frac{\partial}{\partial \chi} \right], \tag{5.29} \]

and the spacelike orthogonal vector \(v\) has a form

\[
u = \frac{1}{a} \left\{ 1 - \left( \frac{c_1 \sin \eta - c_2 \cos \eta}{\sin \chi} \right)^2 \right\}^{-1/2}
\times \left[ \left( \frac{c_1 \sin \eta - c_2 \cos \eta}{\sin \chi} \right) \frac{\partial}{\partial \eta} + \frac{\partial}{\partial \chi} \right]. \tag{5.30} \]

It is not hard to find

\[
D_A\left(\frac{v^A}{r}\right) = \frac{c_1 \cos \eta + c_2 \sin \eta - \cos \chi}{a^2[(c_1 \cos \eta + c_2 \sin \eta)^2 - 1]}
\times \left\{ 1 - \left( \frac{c_1 \sin \eta - c_2 \cos \eta}{\sin \chi} \right)^2 \right\}^{-1/2}. \tag{5.31} \]
This is vanishing on the photon surface. Some calculations show that on the photon surface Eq. (2.6) holds and

$$v^B D_B D_A \left( \frac{v^A}{r} \right) = -\frac{1}{a^3 \sin \chi} < 0. \tag{5.32}$$

So the solution satisfies our Definition 1, and the photon sphere is outer.

Here, we give a summary of the boundary conditions for the photon surface. The photon surface has to be anchored to the surface of the dust ball at $r = 3m$. The energy $E_s$ inside the photon surface has to increase to match (on the boundary of the dust ball) the ADM mass $m$ of the spacetime. Furthermore, the increasing rate of the energy, i.e., $E_s$, at the boundary has to be vanishing because that no matter field will enter into the dust ball anymore and $E_s$ has to arrive at a maximum there. The observer (with four velocity $u$) sitting on the photon sphere is accelerated. From the expression (5.29), it is easy to find that the velocity is infinitely boosted on the boundary and the observer cannot be accelerated any more.

5.3 Numerical calculation

The equation for the photon surface is quite complicated even in the case of marginally bounded collapse. Here, we only show the numerical results. As in the paper by Eardley and Smarr [37], we assume

$$E(x) = x^3, \quad t_0(x) = \xi x^\nu, \quad 0 \leq x < 1,$$
$$E(x) = 1, \quad t_0(x) = x^2 - 1 + \xi, \quad 1 < x < \infty,$$  

(5.33)

where $\xi \geq 0$, and $\nu \geq 1$ is an integer. The boundary of the dust ball corresponds to $r = 1$. Outside the dust ball, the spacetime is the Schwarzschild solution which has a unit ADM mass.

To solve the photon surface equation (5.5), we have to choose suitable boundary conditions. Since the spacetime outside the dust is the standard Schwarzschild spacetime, the location of the photon surface is given by $r = 3m$, where $m$ is the ADM mass. So on the surface of the dust ball, we have $r(1) = 3$. From Eq. (5.6), this means that the photon surface has to be anchored at the point with coordinates $(\xi - \sqrt{6}, 1)$, i.e.,

$$x(\xi - \sqrt{6}) = 1, \tag{5.34}$$

or

$$t|_{x=1} = \xi - \sqrt{6}, \tag{5.35}$$

if we exchange the roles between $x$ and $t$ in Eq. (5.5) and regard $t$ as a function of $x$. Now the boundary condition for $\xi$ will be important to get the photon surface.

Similar to the OS model situation, the crucial point is that the energy $E$ does not change at the boundary of the dust ball because there is no exchange of matter or momentum flux at the boundary. This means the left side of Eq. (4.17) has to be vanishing, and this gives

$$\frac{q}{p} = \tanh \alpha, \tag{5.36}$$

where $\alpha$ is defined in Eq. (3.18), and $q$ and $p$ are given as follows

$$p = T_{AB} v^A v^B = \frac{\epsilon}{1 - r_i^2} (r_i \cosh \alpha + \sinh \alpha)^2, \tag{5.37}$$

and

$$q = T_{AB} v^A u^B = \frac{\epsilon}{1 - r_i^2} (r_i \cosh \alpha + \sinh \alpha) \cdot (r_i \sinh \alpha + \cosh \alpha). \tag{5.38}$$

By these results, we find that on the boundary we have $\tanh \alpha = 1$, i.e., the frame has to be infinitely boosted such that $u$ approaches a null vector. On the photon surface, assume the proper time of the vector $u$ is $\tau$, then we have

$$u = \frac{dt}{d\tau} \frac{\partial}{\partial t} + \frac{dx}{d\tau} \frac{\partial}{\partial x}. \tag{5.39}$$

From Eqs. (3.7) and (3.18), we have

$$\frac{dt}{dx} = -r_i \left( \frac{r_i \sinh \alpha - \cosh \alpha}{r_i \cosh \alpha - \sinh \alpha} \right). \tag{5.40}$$

After substituting Eq. (5.6) and $\tanh \alpha = 1$, on the boundary, we have

$$\frac{dt}{dx} \bigg|_{x=1} = 3 + \frac{\sqrt{6} \nu}{3}. \tag{5.41}$$

The boundary conditions (5.35) and (5.41) are enough to determine the photon surface.

5.3.1 $\nu$ arbitrary, $\xi = 0$

In the previous subsection, an analytic solution for $K = 1$ OS model has been given. Here, the case with $\xi = 0$ actually corresponds to the OS model with $K = 0$. The photon surface can be found in Fig. 3.

Obviously, similar to the case with $K = 1$, the photon surface precedes to the event horizon of the spacetime. Of course, the apparent horizon and the singularity of the spacetime are always at the future of the event horizon.

5.3.2 $\nu = 1$, $\xi$ finite

In this case, with different $\xi$, the result of the gravitational collapse might be a black hole or a naked singularity. When $0 < \xi < 6.3084$, there is no global singularity, and weak cosmological censorship is satisfied [37]. The subfig. (a) in Fig. 1 gives the photon surface for $\xi = 5.0$. A regular event
Fig. 3 $\zeta = 0$, OS model with $K = 0$. The green line corresponds to the photon surface, the red line is the event horizon, and the blue line depicts the apparent horizon.

horizon exists in this case, and the destiny of the dust ball is a black hole. Various geometric objects almost have the same performance as in the case of homogeneous.

However, when $\zeta > 6.3084$, we have a naked singularity. The event horizon in the subfig. (b) in Fig. 4 is singular, and it will end on the null singularity in the center. This center focusing-singularity is not censored. The light ray starting from the singularity can arrive at the future null infinity of the spacetime. The numerical calculation shows that the photon surface is regular. So, for this focusing-singularity, it seems that the difference between the naked singularity and the black hole is not the photon sphere but the optical behavior inside the photon sphere. The black hole has a shadow region inside the photon sphere. Naively, the naked singularity should look brighter than a black hole because of the light rays starting from the singularity. However, the situation is complicated due to the redshift effect and the structure of the spacetime with singularity, and people have found some observation methods to distinguish the global naked singularity and the black hole [20, 21, 42, 43].

5.3.3 $\nu = 2$, $\zeta$ finite

The situation is quite similar to the case with $\nu = 1$. In the case with $0 < \zeta < 9.0307$, a regular event horizon exists, see subfig. (a) in Fig. 5. A naked singularity appears when $\zeta > 9.0307$, this can be found in subfig. (b) in Fig. 5.

5.3.4 $\nu = 3$, $\zeta$ finite

This case is the so-called self-similar gravitational collapse. There is a regular event horizon when $0 < \zeta < 17.3269$. A globally naked singularity appears when $\zeta > 17.3269$. Figure 6 gives the details of these two cases.

5.3.5 $\nu \geq 4$, $\zeta$ finite and arbitrary

For an arbitrary $\zeta$, the destiny of the dust ball is a black hole. There are no (local or global) singularities in the gravitational collapse. The situation is similar to the case of homogeneous.

At the end of this subsection, we give a short summary on the photon surface in the marginally bounded collapse model: The photon surface always emerges regardless that the final state is a black hole or a globally naked singularity, and the photon surface always precedes to the event horizon. Another point is that the event horizon always follows closely after the photon surface.

6 Conclusion and discussion

In this paper, for the spacetime with the symmetry of a maximally symmetric space, we give a quasi-local definition of a photon sphere differ from the one provided by Claudel, Virbhadra, and Ellis. Our definitions base on the geometry of a codimension-2 spacelike surface and independent of the umbilical hypersurface in the spacetime. Unlike the definition based on the umbilical hypersurface, this new definition effectively rules out the photon surface which in the absence of gravity.

By using the definition, we get several results on a photon sphere or a photon surface. The combination of Eqs. (4.12) and (4.15) gives a second-order differential equation for a photon surface, and Eq. (4.17) gives a reasonable boundary condition for this equation. With these results in hand, we can study the photon surface in the model of gravitational collapse.

In the homogenous case, i.e., the OS model, based on the idea for the boundary condition, we have an analytic solution to the photon surface equation. This simple model tells us a lot of common behavior of the photon surface in the gravitational collapse to a black hole. For example, the appearance of the photon sphere is always earlier than the event horizon. The difference between the occurrence times, i.e., $\Delta t$, is mainly determined by the total mass but not the size of the gravitational system. For a massive system with very low density, $\Delta t$ is nearly the same as the system with the same mass but higher density. This $\Delta t$ is quite short even for a supermassive system. So an event horizon is always closely accompanied by a photon surface. Now we can answer the question in the introduction of this paper: in a dynamical collapsing process, the photon surface will not be born very early even if the density of the system is very low. At least in the simple model of the gravitational collapse in this paper, the situation will not happen.

In the LTB model, we further investigate the behavior of the photon surface. We find that the photon surface always appears before the event horizon and the apparent horizon.
Fig. 4 $\nu = 1$

(a) $\zeta = 5.0$, no globally naked singularity.

(b) $\zeta = 8.0$, globally naked singularity.

Fig. 5 $\nu = 2$

(a) $\zeta = 5.0$, no globally naked singularity.

(b) $\zeta = 10.0$, globally naked singularity.

Fig. 6 $\nu = 3$

(a) $\zeta = 10.0$, no globally naked singularity.

(b) $\zeta = 18.0$, globally naked singularity.
both in the case of collapsing into a black hole and a naked singularity. As in the case of homogeneous, in some sense, the event horizon or the globally naked singularity is always covered by a photon sphere. The brightness inside the photon sphere is of course important to distinguish the singularity to the black hole [20–22,42,43]. Most of these discussions is limited in classical physics. However, near the global singularity, quantum effects might be inevitable [22]. What will happen once the quantum effect is involved? This needs further investigation.

The question in front of us is the definition of the photon surface beyond the spherical symmetry. Recently, there are some generalizations to the stationary rotating space-times [44–50]. Similar to our definition here, one way is the generalization of the definition of the photon surface. For example, in [44], Yoshino et. al. have generalized the photon surface to be a transversely trapping surface (TTS). Based on this generalization, they also studied the properties of TTSs for static and axisymmetric stationary spacetimes. Another way is the generalization of the so-called light ring (LR). For example, Cunha et.al. have generalized the LR to be a fundamental photon orbit (FPO) for the generic stationary and axisymmetric spacetimes [50].

So, frankly speaking, for a spacetime without symmetry, how to define a photon sphere or photon surface locally or quasi-locally is still an open question up to date. Probably, our definition based on codimension-2 geometry can provide some clues to this question. Without the spherical symmetry (Kerr spacetime as an example), Definition 1 in this paper is not suitable. Actually, without the spherical symmetry, the Eq. (2.8) has to include shift vectors as well as the lapse functions, and the Eqs. (2.6) and (2.7) might have very different forms which are still not known to us. Also, it is well-known that the photon sphere is replaced by some photon region in Kerr spacetime. How to use the codimension-2 surface to describe the photon region is yet unclear. This point is deserved to be studied in future.
