INTRODUCTION

The brain has traditionally been considered as a target site for peripheral steroid hormones. In addition to this classical concept, it is now established that steroids can be synthesized de novo in the central and peripheral nervous systems. Such steroids are called “neurosteroids.” De novo neurosteroidogenesis in the brain from cholesterol is considered to be a conserved property across vertebrates, (for reviews, see Baulieu, 1997; Tsutsui et al., 2000; Compagnone and Mellon, 2000; Mellon and Vaudry, 2001; Tsutsui et al., 2003, 2006; Tsutsui and Mellon, 2006; Do-Regò et al., 2009).

Seasonally breeding wild animals, such as amphibians, have served as excellent animal models to investigate the biosynthesis and biological actions of neurosteroids. Previous studies over the past two decades have demonstrated that the brain and other nervous systems possess key steroidogenic enzymes and produces pregnenolone and other various neurosteroids in vertebrates in general. Recently, 7α-hydroxy pregnenolone, a novel bioactive neurosteroid, was identified in the brain of newts and quail. Importantly, this novel neurosteroid is produced from pregnenolone through the enzymatic activity of cytochrome P4507α and acts on brain tissue as a neuronal modulator to stimulate locomotor activity in these vertebrates. Subsequently, the mode of action of 7α-hydroxy pregnenolone was demonstrated. 7α-Hydroxy pregnenolone stimulates locomotor activity through activation of the dopaminergic system. To understand the functional significance of 7α-hydroxy pregnenolone in the regulation of locomotor activity, diurnal, and seasonal changes in 7α-hydroxy pregnenolone synthesis were further characterized. Melatonin derived from the pineal gland and eyes regulates 7α-hydroxy pregnenolone synthesis in the brain, thus inducing diurnal locomotor changes. Prolactin, an adrenohypophyseal hormone, regulates 7α-hydroxy pregnenolone synthesis in the brain, and also induces seasonal locomotor changes. In addition, 7α-hydroxy pregnenolone mediates corticosterone action to modulate locomotor activity under stress. This review summarizes the current knowledge regarding the mode of action and functional significance of 7α-hydroxy pregnenolone, a newly identified bioactive neurosteroid stimulating locomotor activity.

OUTLINE OF 7α-HYDROXYPREGNENOLONE AND ITS BIOLOGICAL ACTION

IDENTIFICATION OF 7α-HYDROXYPREGNENOLONE IN THE BRAIN

Our preliminary study initially suggested that the brain of newts actively produces an unknown amphibian neurosteroid from
pregnenolone. Subsequently, Matsunaga et al. (2004) demonstrated that this unknown pregnenolone metabolite is 7α-hydroxy pregnenolone in the newt brain (Figure 1), based on biochemical techniques combined with high-performance liquid chromatography (HPLC), thin-layer chromatography (TLC), and gas chromatography–mass spectrometry (GC–MS) analyses. Tsutsui et al. (2008) further demonstrated that the quail brain also produces 7α- and 7β-hydroxy pregnenolone by using the same biochemical techniques (Figure 1).

**IDENTIFICATION OF CYTOCHROME P4507A IN THE BRAIN**

7α-Hydroxy pregnenolone is considered to be synthesized from pregnenolone through the enzymatic activity of cytochrome P4507α (Figure 1). Haraguchi et al. (2010) identified a cDNA encoding a putative cytochrome P4507α from the newt brain. The newt P4507α cDNA had a full length of 2598 bp. The enzymatic activity of this putative newt P4507α was then demonstrated (Haraguchi et al., 2010). The homogenate of COS-7 cells transfected with the putative newt P4507α cDNA converted pregnenolone into 7α-hydroxy pregnenolone as shown by HPLC analysis, and the inhibitor of cytochrome P450s, ketoconazole, abolished this metabolic process. COS-7 cells without transfection of newt P4507α cDNA did not convert pregnenolone into 7α-hydroxy pregnenolone. 7α-Hydroxy pregnenolone synthesis was further confirmed by GC–MS analysis (Haraguchi et al., 2010).

A full length of 2341 bp cDNA prepared from the quail brain was also identified as encoding a putative cytochrome P4507α (Tsutsui et al., 2008). The enzymatic activity of this putative quail P4507α was demonstrated in homogenates of COS-7 cells transfected with the putative quail P4507α cDNA (Tsutsui et al., 2008). As demonstrated by HPLC and GC–MS analyses, the homogenate converted pregnenolone to 7α-hydroxy pregnenolone. Although it is still unclear whether cytochrome P4507α can also convert pregnenolone to 7β-hydroxy pregnenolone, the presence of 7β-hydroxy pregnenolone as well as 7α-hydroxy pregnenolone is evident in the quail brain (Tsutsui et al., 2008; Figure 1).

The production of 7α-hydroxy pregnenolone in the brain may be a conserved property of vertebrates, because this neurosteroid has also been identified in the brain of mammals (Akwa et al., 1992; Doostzadeh and Morfin, 1997; Weill-Engerer et al., 2003; Yau et al., 2003).

**BIOLOGICAL ACTION OF 7α-HYDROXYPREGNENOLONE**

Because 7α-hydroxy pregnenolone is actively produced in the brain of newts, this seasonally breeding amphibian has served as a suitable animal model to investigate the biological action of 7α-hydroxy pregnenolone. 7α-Hydroxy pregnenolone synthesis in the brain of male newts showed marked changes during the annual breeding cycle, with a maximum level in the spring breeding period when locomotor activity of wild populations of the same species increases (Matsunaga et al., 2004). Matsunaga et al. (2004) therefore analyzed the effect of 7α-hydroxy pregnenolone on locomotor activity. For behavioral testing, newts were placed individually in a water-filled aquarium maintained at 18 ± 2°C; each testing arena was marked with parallel lines to define four equal sectors (Matsunaga et al., 2004). Immediately after administration of 7α-hydroxy pregnenolone, locomotor activity was quantified by counting the total number of lines crossed during a 30-min observation (Matsunaga et al., 2004) according to a previous method (Moore and Miller, 1984; Lowry et al., 2001). Locomotion consisted of a combination of walking and swimming movements (Matsunaga et al., 2004). Administration of 7α-hydroxy pregnenolone acutely increases locomotor activity of male newts in the non-breeding period when endogenous 7α-hydroxy pregnenolone synthesis in the brain is low (Matsunaga et al., 2004). This stimulatory effect occurred in a dose-dependent manner with a threshold dose ranging from 0.5 to 1 ng through intracerebroventricular (i.c.v.) injection, corresponding to the physiological range observed in the brain of normal newts (Matsunaga et al., 2004). Accordingly, 7α-hydroxy pregnenolone may act as a novel neuronal modulator to stimulate locomotor activity of male newts, and the increase in locomotor activity of male newts that occurs during the spring breeding period may be ascribed to an increase in the production of 7α-hydroxy pregnenolone.

Because the quail displays a robust locomotor activity rhythm when held under typical light/dark lighting schemes (Wilson, 1972; Wada, 1979), this bird has also served as an appropriate animal model to investigate the biological action of 7α- and 7β-hydroxy pregnenolone. Both neurosteroids were therefore administered i.c.v. to male quail during night, when activity is low, to examine whether they affect locomotor activity (Tsutsui et al., 2008). For behavioral testing, quail were placed individually in an empty soundproof chamber (Tsutsui et al., 2008). For 30 min after administration of 7α-hydroxy pregnenolone, locomotor activity was measured by using an implantable telemetry system (Tsutsui et al., 2008). A stimulatory dose-dependent effect of 7α-hydroxy pregnenolone was also observed in male quail (Tsutsui et al., 2008). 7β-Hydroxy pregnenolone did not influence locomotor activity (Tsutsui et al., 2008). It

![FIGURE 1](image-url)
thus appears that 7α-hydroxypregnenolone acts as a neuronal modulator to stimulate locomotor activity in male newts.

**MODE OF ACTION OF 7α-HYDROXYPREGNENOLONE**

**7α-HYDROXYPREGNENOLONE ACTION THROUGH DOPAMINERGIC SYSTEM**

To understand the mode of action of 7α-hydroxypregnenolone on locomotion, Matsunaga et al. (2004) measured the concentrations of several monoamines by HPLC-electrochemical detection (ECD) 5 min after an i.c.v. injection of 7α-hydroxypregnenolone to non-breeding male newts. 7α-Hydroxypregnenolone significantly increased the concentration of dopamine in the male newt brain, particularly in the rostral brain region including the striatum, which is known to be involved in the regulation of locomotor behavior (Matsunaga et al., 2004). In contrast, there were no significant differences in the concentrations of other monoamines, i.e., norepinephrine, epinephrine, and 5-hydroxytryptamine (Matsunaga et al., 2004).

7α-Hydroxypregnenolone treatment resulted in a concentration-dependent increase in the release of dopamine from cultured male newt brain tissue with the threshold concentration ranged between $10^{-8}$ and $10^{-7}$ M (Matsunaga et al., 2004). Furthermore, the effect of 7α-hydroxypregnenolone on locomotion was abolished by administration of haloperidol or sulpiride, two dopamine D$_2$ receptor antagonists, but not by administration of the dopamine D$_1$ receptor antagonist SCH23390 (Matsunaga et al., 2004). Accordingly, it is considered that the stimulatory effect of 7α-hydroxypregnenolone on locomotor activity is mediated through dopamine D$_2$ receptors. To recapitulate, 7α-hydroxypregnenolone synthesized actively in the diencephalon and rhombencephalon, by acting on dopaminergic neurons localized in the posterior tuberal nucleus (PT) and ventral tegmental area (VTA), may induce dopamine release from their terminals in the rostral brain region, notably in the striatum and nucleus accumbens (NA), and consequently increase locomotor activity of male newts (Matsunaga et al., 2004; Figure 2).

In the male quail brain, the expression of cytochrome P450$_{α}$ mRNA was localized in the nucleus preopticus medialis (POM), the nucleus paraventricularis magnocellularis (PVN), the nucleus ventromedialis hypothalami (VMN), the nucleus dorsolateralis anterior thalami (DLA), and the nucleus lateralis anterior thalami (LA; Tsutsui et al., 2008). In quail (Tsutsui et al., 2008) as in newts (Matsunaga et al., 2004), 7α-hydroxypregnenolone increased the concentration of dopamine in the telencephalic region that encompasses the striatum (Sanberg, 1983; Sharp et al., 1987; Bardo et al., 1990). In birds, dopaminergic neurons that are located in the mesencephalic region, including the VTA and the substantia nigra (SN), project to the telencephalon notably the striatum (Mezey and Csillag, 2002; Hara et al., 2007). Interestingly, the telencephalic region is enriched with dopamine D$_1$ and D$_2$ receptors in birds (Ball et al., 1995; Levens et al., 2000). Accordingly, 7α-hydroxypregnenolone synthesized actively in the diencephalon, by acting on dopamine neurons localized in the VTA and SN, may induce dopamine release from their termini in the striatum, and consequently increase locomotor activity in male quail as in male newts.
DIURNAL CHANGES IN 7α-HYDROXYPREGNENOLONE SYNTHESIS AND ACTION

To investigate the functional significance of 7α-hydroxypregnenolone in the regulation of locomotor activity, diurnal changes in both locomotor activity and diencephalic 7α-hydroxypregnenolone concentrations were studied in male quail exposed to daily photoperiods of 16/8 h light/dark (LD; lights on at 07:00 a.m., off at 11:00 p.m.). Locomotor activity of males was much higher than that of females from the time of lights on until noon, but thereafter decreased to female levels (Tsutsui et al., 2008). In males, these changes in locomotor activity were correlated with concentrations of diencephalic 7α-hydroxypregnenolone, the maximum value occurring at 11:00 a.m. when locomotor activity was high (Tsutsui et al., 2008). The functional significance of this correlation was supported by the observation that administration of ketoconazole, an inhibitor of P450s, inhibits locomotor activity at 11:00 a.m. (Tsutsui et al., 2008). Thus, the increase in diencephalic 7α-hydroxypregnenolone may be responsible, at least in part, for the higher locomotor activity in males. As mentioned above, the low level of 7α-hydroxypregnenolone synthesis and concentration in the female diencephalon suggests that this neurosteroid may not play a role in female locomotor activity.

REGULATORY MECHANISMS OF DIURNAL CHANGES IN 7α-HYDROXYPREGNENOLONE SYNTHESIS AND ACTION

Melatonin is known to be also involved in the regulation of locomotor activity in birds (Binkley et al., 1971; John et al., 1978; Cassone and Menaker, 1984; Chabot and Menaker, 1992; Hau and Gwinner, 1994; Warren and Cassone, 1995; Murakami et al., 2001), which suggested that melatonin may regulate diencephalic 7α-hydroxypregnenolone synthesis, and thereby influence locomotor activity. To elucidate the mechanism regulating diurnal changes in 7α-hydroxypregnenolone synthesis and 7α-hydroxypregnenolone-dependent locomotor activity, Tsutsui et al. (2008) performed a series of experiments involving melatonin manipulation in male quail. Combination of pinealectomy (Px) and orbital enucleation (Ex) increased the production and concentration of 7α-hydroxypregnenolone and the expression of cytochrome P450α in the quail diencephalon after 1 week. Conversely, melatonin administration to Px/Ex quail decreased the production and concentration of 7α-hydroxypregnenolone and the expression of cytochrome P450α in the diencephalon (Tsutsui et al., 2008). Further, the inhibitory effect of melatonin on 7α-hydroxypregnenolone synthesis was abolished by luzindole, a melatonin receptor antagonist (Tsutsui et al., 2008). Melatonin derived from the pineal gland and eyes therefore may act as an inhibitory factor of 7α-hydroxypregnenolone synthesis in the quail (Figure 3). This notion is supported by the earlier studies indicating that melatonin treatment decreases locomotor activity in quail (Murakami et al., 2001; Nakahara et al., 2003) and other birds (Murakami et al., 2001).

In quail, as in other vertebrates, the nocturnal secretion of melatonin is night-length dependent (Cockrem and Follett, 1985), and the onset of melatonin secretion occurs soon after the onset of darkness (Kumar and Follett, 1993). Therefore, the increase in 7α-hydroxypregnenolone synthesis in the brain of male quail during the light period is likely to be a result of the decrease in endogenous melatonin secretion (Figure 3). Since 7α-hydroxypregnenolone stimulates locomotor activity, it is proposed that, in male quail, this neurosteroid plays a crucial role in diurnal changes in locomotor activity through the action of melatonin.

In birds and other vertebrates in general, locomotor activity undergoes a circadian rhythm (Saper et al., 2005) controlled by diurnal rhythm of melatonin secretion (Binkley et al., 1971; John et al., 1978; Cassone and Menaker, 1984; Chabot and Menaker, 1992; Hau and Gwinner, 1994; Warren and Cassone, 1995). However, the molecular mechanisms underlying this neurohormonal regulation of behavior have been poorly understood. The discovery of the role of 7α-hydroxypregnenolone in mediating the action of melatonin on diurnal locomotor rhythmicity is an important step in understanding these mechanisms (Tsutsui et al., 2008). A similar mechanism may underly the regulation of diurnal locomotor rhythms in other vertebrates (for reviews, see Tsutsui et al., 2009a,b, 2010a,b), since 7α-hydroxypregnenolone is also present in the brains of newts (Matsunaga et al., 2004) and mammals (Akwa et al., 1992; Doostzadeh and Morfin, 1997; Weill-Engerer et al., 2003; Yau et al., 2003).

SEASONAL CHANGES IN 7α-HYDROXYPREGNENOLONE SYNTHESIS AND ACTION

To further understand the functional significance of 7α-hydroxypregnenolone, seasonal changes in 7α-hydroxypregnenolone synthesis and concentration in the brain were also demonstrated in newts (Matsunaga et al., 2004; Haraguchi et al., 2010). Both the synthesis and concentration of 7α-hydroxypregnenolone in the male brain markedly changed during the annual breeding cycle.

**Figure 3** Schematic model depicting the action of melatonin on the regulation of diurnal changes in 7α-hydroxypregnenolone synthesis and locomotor activity in quail. Melatonin acts to reduce cytochrome P450α expression through melatonin receptor-mediated mechanisms. Melatonin derived from the pineal gland and eyes regulates 7α-hydroxypregnenolone synthesis in the brain, thus inducing diurnal locomotor changes. See the text for details.
and were maximum in the spring breeding period (Matsunaga et al., 2004; Haraguchi et al., 2009, 2010). Similar seasonal changes in the expression of cytochrome P450 \( \alpha \)α occurred in the male brain (Haraguchi et al., 2010). These findings suggest that the increase in locomotor activity of male newts in the spring breeding period can be accounted for an increase in 7α-hydroxyprogrenolone synthesis in the brain. In contrast to males, 7α-hydroxyprogrenolone levels in the brain of females did not vary significantly and are constantly low (Haraguchi et al., 2010). Accordingly, the lower locomotor activity in females could be ascribed to a lower level of 7α-hydroxyprogrenolone in their brain.

REGULATORY MECHANISMS OF SEASONAL CHANGES IN 7α-HYDROXYPREGENOLONE SYNTHESIS AND ACTION

Plasma prolactin (PRL) levels in the male newt are elevated during the breeding period (Matsuda et al., 1990; Mosconi et al., 1994) and it has been shown that PRL acts directly on the brain to regulate courtship behavior in the male newt (Toyoda et al., 2005). Based on these observations, PRL may act on the brain to increase 7α-hydroxyprogrenolone synthesis, thus enhancing locomotor activity of male newts during the breeding period. A recent study has provided evidence that PRL is an important regulator of 7α-hydroxyprogrenolone production (Haraguchi et al., 2010; Figure 4). Hypophysectomy (Hypox) decreased 7α-hydroxyprogrenolone synthesis and concentration in the brain of sexually mature males after 2 weeks, suggesting that some pituitary hormone(s) may be involved in the regulation of 7α-hydroxyprogrenolone synthesis in the brain (Haraguchi et al., 2010). Administration of PRL but not gonadotropins (GTHs) to Hypox male newts caused a dose-dependent increase in 7α-hydroxyprogrenolone synthesis and concentration in the brain (Haraguchi et al., 2010). Reciprocally, administration of anti-newt PRL serum dose-dependently decreased 7α-hydroxyprogrenolone biosynthesis (Haraguchi et al., 2010). Accordingly, PRL secreted by the adenohypophysis can be regarded as a major factor regulating 7α-hydroxyprogrenolone synthesis (Figure 4). This is a previously undescribed role of the adenohypophyseal hormone in the regulation of neurosteroidogenesis in the brain in any vertebrate.

In contrast to male newts, no seasonal changes in 7α-hydroxyprogrenolone synthesis and concentration, and cytochrome P450 \( \alpha \)α mRNA expression were observed in female newts (Haraguchi et al., 2010). In newts, plasma PRL levels in males exhibit marked seasonal changes during the annual breeding cycle and are maximum in the spring breeding period (Matsuda et al., 1990; Mosconi et al., 1994). In contrast, plasma PRL levels in females are constantly low (Matsuda et al., 1990). Such a sex difference in the seasonal changes in plasma PRL levels may account for the absence of seasonal changes in 7α-hydroxyprogrenolone synthesis and concentration, and cytochrome P450 \( \alpha \)α mRNA expression in the female brain.

To understand the mode of action of PRL in the regulation of 7α-hydroxyprogrenolone synthesis, Haraguchi et al. (2010) determined the site of cytochrome P450 \( \alpha \)α expression and colocalization of cytochrome P450 \( \alpha \)α and PRL receptor (PRLR) in sexually mature male newts. P450 \( \alpha \)α-positive cells were localized mainly in the anterior preoptic area (POA), magnocellular preoptic nucleus (Mg), and tegmental area (TA) in the brain (Haraguchi et al., 2010). However, PRLR-like immunoreactivity was found only in the Mg (Haraguchi et al., 2010). Thus, the major, but perhaps not exclusive, targets of PRL action to increase 7α-hydroxyprogrenolone synthesis are the P450 \( \alpha \)α-positive cells in the Mg (Figure 4). The Mg is sexually dimorphic in terms of response to pheromones and neuroanatomical aspect (Govek and Swann, 2007). In particular, the Mg possesses more neurons in the male than in the female (Govek et al., 2003). Electrolytic lesions that include the Mg immediately and permanently eliminate male copulatory behavior in the hamster (Powers et al., 1987). In newt (Giorgio et al., 1982; Toyoda et al., 1993), the involvement of PRL in eliciting courtship behavior of males has been reported. Accordingly, it is possible that PRL may also induce the expression of locomotor activity and courtship behavior by increasing 7α-hydroxyprogrenolone synthesis in the Mg of sexually mature male newts (Figure 4).

On the other hand, it is known that in mammals, PRL is synthesized not only in the adenohypophysis but also in a subset of hypothalamic neurons projecting throughout the brain (Fuxe et al., 1977; De Vito, 1988; Emanuele et al., 1992). Based on the preliminary studies conducted by the laboratory of Kikuyama (I. Hasunuma and S. Kikuyama, unpublished observation), PRL was expressed in the newt brain but the expression level might be very low (see Haraguchi et al., 2010). Thus, the localization and function of brain PRL are still unclear in newts. It is considered that adenohypophyseal PRL is more important than brain PRL in the expressions of locomotor activity and courtship behavior, in as much as the increase in plasma PRL levels in breeding male newts (Matsuda et al., 1990; Mosconi et al., 1994) and the suppression of locomotor activity and courtship behavior in Hypox male newts (Toyoda et al., 1993; Haraguchi et al., 2010) have also been reported.

In mammals, choroid plexus PRLR has been proposed to be involved in the transport of PRL from blood into the cerebrospinal...
fluid (Walsh et al., 1987). In the choroid plexus of newts, dense PRLR immunoreactivity and PRLR mRNA signals were observed in the epithelial cells (Hasunuma et al., 2005). Thus, PRL transported from the blood into the cerebrospinal fluid via the choroid plexus receptor is considered to play an important role in the expression of locomotor activity and courtship behavior, although a possible contribution of PRL transported to the brain through retrograde blood flow by the portal system cannot be excluded as reported in mammals (Oliver et al., 1977; Porter et al., 1978).

EFFECTS OF STRESS ON 7α-HYDROXYPREGNENOLONE SYNTHESIS AND ACTION

It is firmly established that locomotor activity of vertebrates changes after acute stress (Lee et al., 1986; Lowry et al., 2009; Hubbard et al., 2010). Numerous studies in various vertebrates document that concentrations of adrenal steroid hormones, namely cortisol or corticosterone, increase shortly after exposure to stressful conditions (Coddington et al., 2007; Kirby et al., 2009). There is also evidence that injection of corticosterone rapidly and dramatically changes male locomotor activity (Moore and Miller, 1984; Mitra and Saposky, 2008; Ricciardella et al., 2010). However, the molecular mechanisms involved in corticosterone regulation of behavioral changes under stress are still obscure.

Based on these observations, we hypothesized that acute stress may increase 7α-hydroxypregnenolone synthesis via corticosterone action in the newt brain, and that 7α-hydroxypregnenolone may subsequently increase locomotor activity. To test these hypotheses, we conducted a series of experiments using the male newt (S. Haraguchi, T. Koyama, S. I. Hasunuma, S. Okuyama, S. Kikuyama, J. L. Do-Rego, H. Vaudry, and K. Tsutsui, unpublished observation). A 30-min restraint stress increased 7α-hydroxypregnenolone synthesis and plasma corticosterone levels in male newts. Hypox decreased 7α-hydroxypregnenolone synthesis, whereas administration of corticosterone to Hypox newts caused an increase in 7α-hydroxypregnenolone synthesis. These results provide new evidence that 7α-hydroxypregnenolone, a key neurosteroid implicated in the induction of locomotion, mediates the action of corticosterone to modulate locomotor activity in newts under stress.

CONCLUSION AND FUTURE DIRECTIONS

In conclusion, 7α-hydroxypregnenolone, a newly discovered amphibian and avian neurosteroid, acts as an important factor stimulating locomotor activity. The stimulatory action of 7α-hydroxypregnenolone is mediated by the dopaminergic system. 7α-Hydroxypregnenolone apparently functions in males but not in females. Melatonin acts on the neurons expressing cytochrome P450α to regulate 7α-hydroxypregnenolone synthesis, thus inducing diurnal locomotor changes. PRL, an adrenohypophyseal hormone, also acts on the neurons expressing cytochrome P450α to regulate 7α-hydroxypregnenolone synthesis, thus inducing seasonal locomotor changes. 7α-Hydroxypregnenolone further mediates the action of corticosterone to modulate locomotor activity under stress.

The synthesis of 7α-hydroxypregnenolone increases during the breeding season and decreases during the non-breeding season. These seasonal changes suggest that 7α-hydroxypregnenolone may be involved in maintaining energy balance via energy conservation during lean times. Future study is needed to demonstrate this hypothesis. In addition, various wild animals migrate just before reproduction. They become very active at the time of migration. 7α-Hydroxypregnenolone may also drive animals to migrate and enhance migratory activity. Avian migration is a good model to demonstrate this hypothesis.
