Cloning and expression of porcine β1,4 N-acetylgalactosaminyl transferase encoding a new xenoreactive antigen

Byrne GW, Du Z, Stalboerger P, Kogelberg H, McGregor CGA. Cloning and expression of porcine β1,4 N-acetylgalactosaminyl transferase encoding a new xenoreactive antigen. Xenotransplantation 2014; 21: 543–554. © 2014 The Authors. Xenotransplantation Published by John Wiley & Sons Ltd

Abstract: Background: Xenograft rejection of pigs organs with an engineered mutation in the GGTA-1 gene (GTKO) remains a predominantly antibody mediated process which is directed to a variety of non-Gal protein and carbohydrate antigens. We previously used an expression library screening strategy to identify six porcine endothelial cell cDNAs which encode pig antigens that bind to IgG induced after pig-to-primate cardiac xenotransplantation. One of these gene products was a glycosyltransferase with homology to the bovine β-galactosaminyltransferase (B4GALNT2). We now characterize the porcine B4GALNT2 gene sequence, genomic organization, expression, and functional significance.

Methods: The porcine B4GALNT2 cDNA was recovered from the original library isolate, subcloned, sequenced, and used to identify a bacterial artificial chromosome (BAC) containing the entire B4GALNT2 locus from the Children’s Hospital Oakland Research Institute BAC-PAC Resource Centre (#AC173453). PCR primers were designed to map the intron/exon genomic organization in the BAC clone. A stable human embryonic kidney (HEK) cell line expressing porcine B4GALNT2 (HEK-B4T) was produced. Expression of porcine B4GALNT2 in HEK-B4T cells was characterized by immune staining and siRNA transfection. The effects of B4GALNT2 expression in HEK-B4T cells was measured by flow cytometry and complement mediated lysis. Antibody binding to HEK and HEK-B4T cells was used to detect an induced antibody response to the B4GALNT2 produced glycan and the results were compared to GTKO PAEC specific non-Gal antibody induction. Expression of porcine B4GALNT2 in pig cells and tissues was measured by qualitative and quantitative real time reverse transcriptase PCR and by Dolichos biflorus agglutinin (DBA) tissue staining.

Results: The porcine B4GALNT2 gene shares a conserved genomic organization and encodes an open reading frame with 76 and 70% amino acid identity to the human and murine B4GALNT2 genes, respectively. The B4GALNT2 gene is expressed in porcine endothelial cells and shows a broadly distributed expression pattern. Expression of porcine B4GALNT2 in human HEK cells (HEK-B4T) results in increased binding of antibody to the B4GALNT2 enzyme, and increased reactivity with anti-Sd^a and DBA. HEK-B4T cells show increased sensitivity to complement mediated lysis when challenged with serum from primates after pig to primate cardiac xenotransplantation. In GTKO and GTKO:CD55 cardiac xenotransplantation recipients there is a significant correlation between the induction of a non-Gal antibody, measured using GTKO PAECs, and the induction of antibodies which preferentially bind to HEK-B4T cells.

Key words: antigen – B4GALNT2 – cardiac xenotransplantation – immune response – porcine

Abbreviations: B4GALNT2, β1,4 N-acetylgalactosaminyltransferase; BLAST, Basic local alignment search tool; DBA, Dolichos biflorus agglutinin; Gal, galactose α 1,3, galactose; GalNAc, N-acetylgalactosamine; GTKO, pigs with a GGTA-1 a-galactosyltransferase mutation; HEK, human embryonic kidney cells; HEK-B4T, HEK cells expressing the porcine B4GALNT2 gene; HUVEC, Human umbilical vein endothelial cells; Mwwf-1, modifier of von Willebrand factor-1 mutation; Neu5Gc, N-acetylneuraminic acid; PAEC, porcine aortic endothelial cell; PBMC, peripheral blood mononuclear cell; RT-PCR, reverse transcriptase dependent polymerase chain reaction; Sda, The SID blood group expressing a Gal(1-4)[Neu5Ac α2:3]Gal β1-3GalNAc β1-3Gal terminal glycan.

Conclusion: The functional isolation of the porcine B4GALNT2 gene from a PAEC expression library, the pattern of B4GALNT2 gene expression and its sensitization of HEK-B4T cells to antibody binding and complement mediated lysis indicates that the enzymatic activity of porcine B4GALNT2 produces a new immunogenic non-Gal glycan which contributes in part to the non-Gal immune response detected after pig-to-baboon cardiac xenotransplantation.

Introduction

Carbohydrate modifications on glycoproteins and glycolipids are involved in a wide array of biological processes including protein stability, development, and cell growth. Variations in carbohydrate modification between individuals and between species define a form of immune self-recognition. Differences in expression of ABH blood group antigens between individuals has long been recognized as a prohibitive boundary across which blood transfusion and organ transplantation is generally not performed. Individuals which do not express a particular ABH antigen are stimulated by intestinal microflora to produce antibody to that glycan. This preformed antibody can induce a hemolytic reaction or promote hyperacute or accelerated allograft rejection of ABH incompatible grafts. The same process occurs across species. Humans and Old World primates do not produce oligosaccharides with terminal galactose α 1,3, 4-galactose (αGal), whereas all other mammals synthesize terminal αGal glycans [1]. As a consequence, humans make high levels of anti-Gal antibody. Anti-Gal antibody is a major immune barrier to xenotransplantation [2]. This antibody has also been implicated in other clinical pathologies, notably the accelerated calcification of glutaraldehyde-fixed porcine bioprosthetic material and degeneration of bioprosthetic replacement heart valves [3,4].

Targeted genetic modification has been used to mutate the α-galactosyltransferase (GGTA-1) gene of the pig (GTKO) [5–7]. This mutation eliminates the enzyme function and, when homozygous, blocks the synthesis of terminal αGal moieties on glycoproteins [8–11]. Porcine GTKO tissue does not bind anti-Gal antibody and transplantation of GTKO cells, tissue and organs does not induce a specific anti-Gal antibody response. Elimination of this antigen has not eliminated GTKO xenograft rejection which remains a predominantly antibody-mediated process now directed to non-Gal antigens [12,13]. We have used proteomic analysis of porcine aortic endothelial cell (PAEC) membranes and expression library screening of PAEC cDNA libraries to identify immunogenic non-Gal target antigens that may contribute to xenograft rejection [14,15]. Using sera, obtained after pig-to-baboon cardiac xenotransplantation, these studies identified 43 potential non-Gal target antigens including six cDNAs, isolated from PAEC expression libraries. When expressed on human embryonic kidney 293 cells (HEK) these cDNAs each produce a porcine antigen that binds to baboon non-Gal IgG. A BLAST search identified one of these recovered cDNAs as a porcine glycosyltransferase with homology to a predicted Bos Taurus β1,4 N-acetylgalactosaminyltransferase (B4GALNT2) sequence [14]. In humans and mice the B4GALNT2 gene catalyzes the terminal addition of N-acetylgalactosamine to a sialic acid modified lactosamine to produce GalNAc β1-4[Neu5Ac α2-3]Gal β1-4GlcNAc β1-3Gal, the Sdα (Sid blood group, also known as CAD or CT) blood group antigen [16,17]. In this study, we further characterize the porcine B4GALNT2 coding sequence, genomic organization, expression, and functional significance.

Materials and methods

Cells, culture conditions, and transfection methods

Porcine aortic endothelial cells (PAECs) were isolated from GTKO A- and O-type blood group pig aortas as previously described [18] and cultured in EGM media (Lonza Inc., Allendale, NJ, USA). Porcine peripheral blood mononuclear cells (PBMCs) were isolated from GTKO pig blood by density gradient centrifugation using Ficoll–Hypaque. Human embryonic kidney 293 cells (HEK) and HEK cells expressing the porcine B4GALNT2 cDNA were grown in DMEM media with 10% FBS at 37 °C in a 5% CO2 incubator. The full length pig B4GALNT2 open reading frame was amplified from the original library isolated clone using a primers set containing a Kozak consensus sequence and in-frame translation stop signals, respectively (Forward: 5’- ACCATGACTTTCGTA CAGCCCTAG-3’, Reverse: 5’- CAGATACCTTAA GGTGCACATTTGGGAG-3’). The PCR product
Porcine B4GALNT2 encodes a new xenoreactive antigen

was inserted into pcDNA3.1/V5-His TOPO expression vector (Life Technologies, Paisley, UK) and transfected into HEK cells using Lipofectamine-2000 (Life Technologies). A stable G418 resistant HEK clone expressing the porcine B4GALNT2 genes (HEK-B4T) was established and used for further real-time RT-PCR, immunohistochemical staining, complement dependent cytotoxicity, and flow cytometry analysis.

siRNA isolation and transfection

B4GALNT2 specific siRNA and control siRNA for glyceraldehyde 3-phosphate dehydrogenase (GAPDH) were generated from the coding region of each gene using a BLOCK-iT Dicer RNAi Kit (Life Technologies) according to the manufacturer’s instruction. RNAi primers for B4GALNT2 were: Forward: 5’-ATGACTTCCGTACAGCCCTAG-3’ and Reverse: 5’-CAGATACCTTAGGTGGCACATGGGAG-3’. RNAi primers for GAPDH were Forward: 5’-AGTGTAAGGTCGGAGTAGCTCA-3’ and Reverse: 5’-AGTGGTCGTTGAGGCAATG-3’. The diced siRNA was purified through a RNA Spin Cartridge (Life Technologies). B4GALNT2 and GAPDH dic siRNAs were transfected into HEK-B4T cells using Lipofectamine-2000 (Life Technologies). After 48 h, total RNA was extracted from cells using RNeasy Plus Mini kit (Qiagen Inc., Valencia, CA, USA). B4GALNT2 expression was monitored by real-time RT-PCR and immunohistochemical staining.

Real-time and qualitative RT-PCR analysis of B4GALNT2 expression

Total RNA was extracted from cultured cells using RNeasy Plus Mini kit (Qiagen Inc.). Porcine tissue RNA was extracted using 1 g of frozen pig tissue homogenized in 10 ml cold STAT-60 RNA (Tel-Test Inc., Friendswood, TX, USA) and processed as recommended. For both qualitative and quantitative reverse transcriptase PCR (RT-PCR) RNA quality was assessed using an Agilent 2100 Bioanalyzer (Agilent Technologies Inc., Santa Clara, CA, USA).

To survey the expression of porcine B4GALNT2 a gene specific one-step reverse transcriptase PCR (RT-PCR) assay using 0.5 μg of total tissue RNA and primers for pig B4GALNT2 (Forward: TACAGCCCTAGATGCTGTTC in exon 1, Reverse: CTCTCCTCTGAAAAGTTGGTCCAG in exon 3) was used to amplify a 334 bp product. Primers for beta-actin (Forward: CAAAGATCATCGCGCCTCA exon 6, Reverse: ACTCTGCTTGGTGATCCACATCT, exon 6) produce a 108 bp product which was used as a loading control. The authenticity of each amplified PCR product was confirmed by sequencing. Gene specific amplification was performed in a MyCycler Thermal Cycler (Bio-Rad, Hercules, CA, USA) using one-step RT-PCR reaction (USB-Affymetrix, Santa Clara, CA, USA) with reverse transcription performed at 50 °C for 30 min. Amplification conditions consisted of 95 °C for 10 min, and 30 cycles of 94 °C for 30 s, 60 °C for 30 s and 72 °C for 30 s. Amplification products were run in a 1.5% agarose gel.

For quantitative real-time analysis (Figs 3C and 4B) QuantiTect SYBR Green one-step RT-PCR was used (Qiagen Inc.) according to the manufacturer’s instruction. The cycling conditions were as follows: 50 °C for 30 min for reverse transcriptase, 95 °C for 15 min, and 40 cycles of 94 °C for 15 s, 60 °C for 30 s, and 72 °C for 30 s. The B4GALNT2 primers for quantitative real time PCR (Fig. 3C) were: rt-Forward: 5’-GCGACTCCAAA-GAATTGGCTTC-3’ (exon 10) and rt-Reverse 5’-TGGTGACCTATGATCAGGTG-3’(exon 11) which produces a 120 bp RT-PCR product. A normalized dCT was calculated using β-actin expression and the relative change in B4GALNT2 expression, ddCT, was calculated based on B4GALNT2 expression in the absence of siRNA [19]. Pig and PAEC AO blood group determination was performed as described [20].

Cell staining and flow cytometry

Fluorescein isothiocyanate conjugated Dolichos biflorus agglutinin (FITC-DBA; Vector Labs, Burlingame, CA, USA) and an anti-Sd antibody KM694 (kindly provided by Kyowa Hakko Kirin Co. Ltd., Tokyo, Japan) were used to detect the glycan products of porcine B4GALNT2 expression in cultured human cells. Cells (2.5 × 105) in FACS buffer (phosphate buffered saline (PBS) with 1% bovine serum albumin) were stained with 1 to 5 μg/ml KM694 or 10 μg/ml of FITC-DBA for 45 min at 4 °C. Cells stained with KM694 were washed in FACS buffer and subsequently stained with a FITC conjugated goat anti-mouse IgM (2 μg/ml Southern Biotech, Birmingham, AL, USA). All cells were analyzed using a FACSCalibur (BD Biosciences, San Jose, CA, USA) cytometer and CellQuest software.

Immunohistochemical staining of HEK and HEK-B4T cells with rabbit anti-human B4GALNT2 (Sigma-Aldrich, Saint Louis, MO, USA) was used to assess B4GALNT2 protein expression after siRNA transfection. Cells were fixed in cold methanol, washed with PBS containing 0.1% Triton X-100, and incubated for 20 min in 0.1% Triton X-100 in PBS.
X-100 and blocked with 10% non-immune serum. Cells were incubated with rabbit anti-human B4GALNT2 in FACS buffer (1 : 75 dilution) for 2 h and washed with PBS. Anti-B4GALNT2 binding was detected with an anti-rabbit diaminobenzidine kit (ZymedLife Technologies, Paisley, UK) as recommended by the manufacturer.

Induced antibody directed to the B4GALNT2 produced porcine glycan after pig-to-baboon heterotopic GTKO or GTKO:CD55 cardiac xenotransplantation was measured by comparing differential antibody binding to HEK and HEK-B4T cells. Cells (2.5 × 10^5) were stained with pre-transplant, and post-explant serial serum dilutions (1 : 5 to 1 : 40) at 4 °C for 45 min in FACS buffer. After washing, bound antibody was detected using a phycoerythrin conjugated goat anti-human IgM or IgG secondary. Induction of antibody specific for the B4GALNT2 produced glycans was estimated as the ratio of induced antibody binding to HEK-B4T cells compared to HEK cells (anti-B4GALNT2 glycan = MFI post explant (HEK-B4T)/pretransplant (HEK-B4T)); MFI post-transplant (HEK)/pretransplant (HEK). Post-explant induction of non-Gal antibody was measured using GTKO PAECs as previously described using serum samples from earlier GTKO or GTKO:CD55 heterotopic cardiac transplants [11] or transplant recipients subject to similar immune suppression. The induced antibody binding data were used to calculate a Spearman rank correlation coefficient for IgM and IgG specific reactivity to HEK-B4T cells and GTKO PAECs. A two tailed non-directed P-value < 0.05 was considered significant. In Table 2, the induced HEK-B4T antibody response is represented in a semi-quantitative scale with ratios <2 scored as negative, 2.0 to 2.5 +, 2.5 to 5.0 ++, 5.0 to 10.0 ++++, and greater than 10 +++++.

Complement-mediated lysis

Human embryonic kidney and HEK-B4T cells (2 × 10^5) were incubated with a dilution of heat inactivated baboon serum at 4 °C for 45 min, washed with PBS, and resuspended in 20% fresh rabbit complement (Sigma-Aldrich) at 37 °C for 1 h. Cell were stained with propidium iodide (3 µg/ml) placed on ice and analyzed on a FACS Calibur flow cytometer. Samples were analyzed in triplicate and the average proportion of propidium iodide stained cells is reported. Baboon serum came from previously described pig to primate cardiac xenograft recipients [14,21]. Serum heat inactivation was performed at 56 °C for 30 min using a temperature controlled water bath.

DBA lectin staining of pig tissues

Fresh pig tissues were embedded and snap frozen in optimal cutting temperature material (OCT. Miles Laboratories, Elkhart, IN, USA). Sections (8 µm) were cut, air dried, and acetone fixed prior to staining. Sections were cleared of OCT by washing in distilled water and PBS, blocked with FACS buffer and stained with FITC-DBA (4 µg/ml) in FACS buffer at 4 °C overnight, washed with PBS and mounted in Vectashield mounting medium with DAPI (Vector Laboratories, Burlingame, CA, USA). Stained sections were photographed using a Leica DM14000B fluorescent microscope (Leica Microsystems, Buffalo Grove, IL, USA).

Results

Sequence analysis and genomic organization

Expression screening of a porcine aortic endothelial cell (PAEC) library using IgG induced after pig-to-baboon cardiac xenotransplantation isolated a porcine cDNA with 54 base pairs of 5' untranslated sequence, a 1509 base pair open reading frame and 459 bp of 3' untranslated sequence including a putative polyadenylation sequence (Fig. 1A, GenBank accession: KF501048). A BLAST search identified this cDNA as a porcine glycosyltransferase with homology to known or predicted β1,4 N-acetylgalactosaminyltransferase (B4GALNT2) products from several mammalian species including the human and mouse B4GALNT2 proteins. A comparison of these protein sequences shows the porcine open reading frame to have 76 and 70% amino acid identity to human and murine B4GALNT2, respectively (Fig. 1B). In contrast amino acid identity to the related human and murine B4GALNT1 protein is 50% (data not shown). Analysis of the porcine protein sequence with the NCBI Conserved Domain Database [22] identified a putative GT-A type fold (underlined). This region includes a conserved structural motif (SQVT TKYVLWVDDDF), present in both human and murine B4GALNT2, which contains an acidic divalent cation binding site (DXD) commonly found in glycosyltransferases which use a UDP-sugar as the donor substrate [23].

To map the genomic organization, the porcine B4GALNT2 cDNA was used to identify a porcine BAC clone obtained from the Children's Hospital Oakland Research Institute BACPAC Resource Centre (#AC173453). Based on the intron/exon structure of human and mouse B4GALNT2 and the porcine genomic sequences derived from the Sus scrofa working draft of AC173453.2, clone...

Byrne et al.

RP44-32E24, we generated a series of primers (Table 1) to confirm the intron exon structure of the porcine B4GALNT2 gene (Fig. 2A). These primers amplified exons 1 to 11, including variable lengths of neighboring intron sequence, and amplified introns 5 to 8 and 10. All PCR products were sequenced and compared to the original B4GALNT2 cDNA to identify intron-exon junction sequences (Fig. 2B). The cDNA coding region is composed of 11 exons spread across approximately 40,000 base pairs. Exon 1 contains translation initiation start site and 5' untranslated sequences. We have not directly mapped the transcriptional start site of the gene so there may be additional 5' untranslated sequence or an upstream exon(s) not depicted in this figure. During the course of this study, a sequence for porcine B4GALNT2 99% identical to the clone we reported was added to the database (NM_001244330).

Expression of porcine B4GALNT2 in human HEK cells

A stable G418 resistant HEK cell line expressing the porcine B4GALNT2 cDNA (HEK-B4T) was produced. This cell line bound higher levels of rabbit anti-human B4GALNT2 antibody (Fig. 3A) compared with control HEK cells. The increased antibody binding was specific for expression of porcine B4GALNT2 mRNA as HEK-B4T cells transfected with siRNA to porcine B4GALNT2 exhibit an 80% decrease in porcine B4GALNT2 mRNA expression and a proportionate reduction in anti-human B4GALNT2 antibody binding (Fig. 3B, C). No change in anti-B4GALNT2 staining or expression of B4GALNT2 mRNA was evident when cells were transfected with siRNA for GAPDH.

The human and mouse B4GALNT2 gene produces GalNAc β1-4[Neu5Ac α2-3]Gal β1-4GlcNAc β1-3Gal, the Sdα blood group glycan, by the addition of a β1,4 N-acetyl galactosamine to a sialic acid modified lactosamine acceptor. HEK cells, but not HUVECs, bind a low level of anti-Sdα hybridoma KM694 (Fig. 3D). The HEK-B4T cell line shows increased binding of KM694 consistent with increased synthesis of the Sdα antigen as a result of expression of porcine B4GALNT2. The Dolichos biflorus agglutinin (DBA) binds alpha linked terminal GalNAc structures [24], but also binds beta GalNAc residues as presented in the Sda glycan. The DBA lectin has been used to isolate the Sdα pentasaccharide from murine small intestine [25], shows differential binding to humans Sdα⁺ and Sdα⁻ glycoproteins [26], and is commonly used to detect the Sdα antigen on cells and in tissue sections [17,27,28]. HEK-B4T cells bind high levels of DBA and are strongly agglutinated by this lectin (Fig. 3E). Expression of porcine B4GALNT2 in HEK-B4T cells increases cell sensitivity to complement mediated cytotoxicity (Fig. 3F). HEK-B4T cells show a 20-fold enhancement of antibody-dependent complement-mediated lysis compared to HEK cells when challenged with pig-to-baboon cardiac xenotransplantation sensitized recipient serum.

Table 1. Primers for mapping the porcine B4GALNT2 genomic structure

| No. | ID       | Sequence            | BP to exon | Site |

| 26  | Intron10-R | TGTTGACCTATGATGCGTCTG | n/a        | in exon 11 |

The table lists the names, sequences, and location of primers used to confirm the genomic organization of the porcine B4GALNT2 gene. Primer numbers (No.) correspond to values in Fig. 2A. Not applicable, n/a.

Immunogenicity of B4GALNT2 produced antigens

Heterotopic GTKO or GTKO:CD55 cardiac xenograft recipients show variable induction of IgG and IgM binding to GTKO PAECs (Table 2). Comparing pretransplant and post explant serum (obtained from immune suppressed recipients 1 to 3 weeks after organ recovery) three recipients (survival 28, 27, and 22 days) showed a clear 2- to 8-fold increase in non-Gal antibody and four recipients (survival 71, 31, 21, and 18 days) showed a minimal non-Gal antibody response. We used differential antibody binding to HEK-B4T and HEK cells to determine if this induced non-Gal antibody response included antibody reactivity specific to the glycans expressed on the HEK-B4T cell.
Porcine B4GALNT2 encodes a new xenoreactive antigen

A

Fig. 2. Schematic representation of the intron-exon organization (A) and splice junction sequences (B) of the porcine B4GALNT2 gene. (A) Shaded boxes represent exon coding sequences numbered E1–E11. Open boxes correspond to untranslated sequences present in the cDNA. The size of each exon is indicated in base pairs above each box and the intron distances are indicated below each exon. The primer pairs (1–26, see Table 1) and amplified products used to analyze the genomic structure from a BAC clone are illustrated below the genomic structure as solid bars for products covering exon/intron boundaries and open bars for products spanning entire introns. The primer numbering corresponds to the primers listed in Table 1. (B) The proximal splice donor and distal splice acceptor nucleotide sequences (upper case) for each exon are shown. Adjacent intervening intron sequences (lower case) are shown. Exon numbering corresponds to (A).

Fig. 2. Schematic representation of the intron-exon organization (A) and splice junction sequences (B) of the porcine B4GALNT2 gene. (A) Shaded boxes represent exon coding sequences numbered E1–E11. Open boxes correspond to untranslated sequences present in the cDNA. The size of each exon is indicated in base pairs above each box and the intron distances are indicated below each exon. The primer pairs (1–26, see Table 1) and amplified products used to analyze the genomic structure from a BAC clone are illustrated below the genomic structure as solid bars for products covering exon/intron boundaries and open bars for products spanning entire introns. The primer numbering corresponds to the primers listed in Table 1. (B) The proximal splice donor and distal splice acceptor nucleotide sequences (upper case) for each exon are shown. Adjacent intervening intron sequences (lower case) are shown. Exon numbering corresponds to (A).

Porcine B4GALNT2 encodes a new xenoreactive antigen

A panel of pig tissues was assessed for B4GALNT2 expression by qualitative RT-PCR. Expression of B4GALNT2 RNA was evident in cultured PAECs, peripheral blood mononuclear cells and at variable levels in most GT+ porcine tissues (Fig. 5A). Expression of B4GALNT2 RNA was not strongly affected by the GGTA-1 Gal genotype as heterozygous (GGTA-1+/−) and GTKO pig tissues exhibited a similar pattern of B4GALNT2 expression (data not shown). Quantitative real time RT-PCR analysis of B4GALNT2 gene expression in cultured GT+ and GTKO PAECs of the A- and O-type blood groups showed only moderate variation in B4GALNT2 expression (Fig. 5B). Expression of porcine B4GALNT2 in HEK-B4T cells resulted in increased DBA and KM694 antibody binding in HEK-B4T cells (Fig. 3D,E), however, PAECs show only strong DBA agglutination (Fig. 5C) and do not stain with the anti-Sdα antibody KM694 (Fig. 5D). DBA staining of GTKO pig tissues (O-type blood group) was observed in vascular endothelial cells of the heart, in glomeruli and larger blood vessels in the kidney and by the reticuloendothelial cells of the liver (Fig. 5E–G).
The porcine B4GALNT2 cDNA was originally isolated during a flow cytometry based library screen to identify human HEK cells expressing porcine cDNAs which encoded surface membrane antigens that bound to sensitized primate IgG after GT⁺ or GTKO pig cardiac xenotransplantation [14]. The porcine cDNA and its encoded protein show the highest homology to the B4GALNT2 gene with 76 and 70% amino acid identity with the human and mouse gene, respectively (Fig. 1). We show that the porcine gene also shares with human and mouse a conserved intron/exon genomic organization (Fig. 2). Consistent with a conserved protein sequence a stable HEK cell line expressing the porcine cDNA (HEK-B4T) binds increased levels of rabbit anti-human B4GALNT2 antisera and, using siRNA inhibition, we show this binding is dependent on expression of the porcine cDNA (Fig. 3B,C). Expression of the porcine cDNA in HEK-B4T cells also results in increased binding of anti-Sda antibody and DBA lectin.

Discussion

The porcine B4GALNT2 cDNA was originally isolated during a flow cytometry based library screen to identify human HEK cells expressing porcine cDNAs which encoded surface membrane antigens that bound to sensitized primate IgG after GT⁺ or GTKO pig cardiac xenotransplantation [14]. The porcine cDNA and its encoded protein show the highest homology to the B4GALNT2 gene with 76 and 70% amino acid identity with the human and mouse gene, respectively (Fig. 1). We show that the porcine gene also shares with human and mouse a conserved intron/exon genomic organization (Fig. 2). Consistent with a conserved protein sequence a stable HEK cell line expressing the porcine cDNA (HEK-B4T) binds increased levels of rabbit anti-human B4GALNT2 antisera and, using siRNA inhibition, we show this binding is dependent on expression of the porcine cDNA (Fig. 3B,C). Expression of the porcine cDNA in HEK-B4T cells also results in increased binding of anti-Sda antibody and DBA lectin. On this structural and functional data, we conclude that the isolated porcine cDNA encodes the porcine B4GALNT2 gene.

Porcine B4GALNT2 enzymatic activity has been reported from swine large intestine mucosal cells [29] and immunostaining of the Sd⁰ antigen has been detected in porcine primordial germ cells [30]. To our knowledge, this is the first molecular analysis of porcine B4GALNT2 gene expression in pig tissues. In the pig, we find B4GALNT2 mRNA
Porcine B4GALNT2 encodes a new xenoreactive antigen

expression in PAECs, peripheral blood mononuclear cells, and across a wide array of tissues (Fig. 5A). This porcine B4GALNT2 gene expression pattern is in distinct contrast to humans and most strains of mice where B4GALNT2 expression and the Sda antigen, generally detected by lectin staining, is largely restricted to gastrointestinal, skin and renal tissues and is notably absent from arteries, heart and skeletal muscle [23,27,31,32]. Vascular expression of B4GALNT2 is not unprecedented however as mice which carry the modifier of von Willebrand factor-1 (Mvwf1) mutation exhibit a shift from gastrointestinal epithelial cell expression to vascular endothelial cell expression of B4GALNT2 [27].

The B4GALNT2 cDNA was originally isolated by screening an expression library with post transplant IgG from pig-to-baboon cardiac heterotopic xenotransplantation recipients transplanted without T-cell immune suppression [14,21]. In these recipients, the non-Gal immune response was especially strong and five of five transplant recipients showed an induced immune response with preferential binding to HEK-B4T cells [14]. In this study, we extend our previous results and show in recipients subject to substantial immune suppression that there is a correlation between an induced non-Gal antibody response and the induction of antibody with preferential binding to HEK-B4T cells (Table 2). We further show that expression of the porcine B4GALNT2 gene in HEK-B4T cells produced a 20-fold enhancement to complement mediated lysis (Fig. 3F). These results and the pattern of B4GALNT2 gene expression strongly indicate that the porcine B4GALNT2 enzyme produces an immunogenic non-Gal glycan on endothelial cells which contributes in part to the non-Gal immune response after pig-to-baboon cardiac xenotransplantation.

The precise structure of the glycan(s) produced on pig endothelial cells by the B4GALNT2 enzyme remains under investigation. Classically in humans and mice expression of B4GALNT2 produces the Sda antigen. Consistent with this we detect increased expression of the Sdα antigen, based on KM694 antibody and DBA lectin binding, in HEK-B4T cells but surprisingly do not observe anti-Sdα KM694 antibody binding to PAECs. It is unclear why this is the case. Ongoing glycan profiling of HEK and HEK-B4T cells suggests that the porcine B4GALNT2 enzyme may produce a wider variety of GalNAc glycans in HEK-B4T cells then normally attributed to the human of mouse enzyme (data not shown). Alternatively KM694 binding may be affected by the presentation of the Sdα epitope on pig cells, possibly due to inclusion of N-glycolylneuraminic acid (Neu5GC) in the structure. In any case, our absorption experiments (Fig. 4) show that GTKO PAECs and HEK-B4T cells share B4GALNT2 dependent antigens which are not present on HUVECs. Interestingly, an induced antibody response in baboons to trace acidic cardiac glycolipids has been reported [8]. Whether this antibody response is related to the glycan produced by B4GALNT2 remains to be determined.

There are a limited set of potential antibody and glycan antigen combinations which may be involved in xenogeneic antibody dependent inflammatory processes. Antibody to the Gal antigen is the dominant xenoreactivity in both humans and Old World non-human primates [1]. Anti-Gal antibodies are known to be sufficient to induce organ rejection of Gal-positive vascular grafts [33–35] and to accelerate calcification of
fixed bioprosthetic animal tissue [3,36]. Humans, but not nonhuman primates, also make a complex array of antibody to a common mammalian sialic acid modification Neu5GC [37]. This antibody reactivity is widely expected to contribute to xeno-graft rejection in humans [38–41] but its significance remains uncertain due to the absence of anti-Neu5GC antibody in experimental non-human primate models. Screening strategies based on panels of defined oligosaccharides have failed to detect xenogeneic sensitization to other common oligosaccharides (Forsman antigen and α- and β-lactosamine) [42,43]. The results presented in this study indicate that porcine B4GALNT2 produces an immunogenic non-Gal glycan which contributes to the induced non-Gal antibody response in the pig-to-baboon xenotransplant model. It remains to be determined if antibody to this glycan contributes to xenograft rejection. Additionally, while most humans express low levels of anti-Sdα antibody which agglutinates rare human red blood cells with high levels of Sdα antigen (CAD or super Sdα) [17], whether an anti-Sdα immune response will occur in humans exposed to porcine tissues and the relationship between human anti-Sdα antibody and the immune response in observed baboons remains to be determined.

Acknowledgments

We acknowledge the technical help contributed by Karen Schumacher for writing this manuscript. This research was funded by an Immunobiology of Plant Fund.
Xenotransplantation cooperative research grant (AI066310) from the National Institute of Allergy and Infectious Disease at the National Institute of Health, by Comprehensive Biomedical Research Centre funds from the National Institute of Health Research, and supported by the National Institute for Health Research University College London Hospitals Biomedical Research Centre.

Author contribution

Guerard W. Byrne: Dr. Byrne contributed to the concept and design of the research, data acquisition, analysis and insight in interpreting the results. He was responsible for drafting and critical revision of the manuscript, contributed to securing funding, and gave final approval for the article.

Zeki Du: Dr. Du was responsible for data acquisition, analysis, and interpretation of the results. He contributed to the drafting of the manuscript and gave final approval.

Paul Stalboeger: Mr. Stalboeger was responsible for data acquisition, analysis, and interpretation of the results. He contributed to the drafting of the manuscript and gave final approval.

Heide Kogelberg: Dr. Kogelberg was responsible for data acquisition, analysis, and interpretation of the results. She contributed to the drafting of the manuscript and gave final approval.

Christopher G. A. McGregor: Dr. McGregor contributed to the concept and design of the research, was primarily responsible for securing funding to support this work, provided critical review and final approval of the article.
