**ABSTRACT**

The complete plastome of *Pinellia peltata* is reported in this study. The whole plastome contains 164,293 bp, including a large single copy region (90,089 bp) and a small single copy region (24,871 bp), which were separated by a pair of inverted repeat regions (24,881 bp of IRB and 24,982 bp of IRA). Totally, 130 genes were identified, containing 86 coding-protein, 8 rRNA (4 rRNA species), and 36 tRNA genes. Phylogenetic analysis based on common protein coding genes of 10 Araceae species showed that *P. peltata* is original than other species in the genus Pinellia. The whole plastome of *P. peltata* and other species should facilitate further works for the genus Pinellia about genetic diversity, phylogenetic analysis, and so on.

*Pinellia peltata* (Araceae) is a relative species of *P. ternata*, which is an important Chinese Traditional Medicine. *P. peltata* is distinguished from other relatives in the genus *Pinellia* by the peltate leaf blade and development of stem tuber (Zhu et al. 2007). Individuals of *P. peltata* used to sequencing are collected from wild (Wenzhou, Zhejiang Province, China) and cultured in laboratory (Guizhou University, Guiyang, Guizhou Province, China).

Total DNA were extracted from young leaves of one individual using a modified CTAB method (Doyle and Doyle 1987) and sequenced by Illumina NovaSeq Platform (Illumina, San Diego, CA) with paired-end mode. Totally, 31,530,954 reads (4,729,643,100 bp) were obtained. After removal of adapter sequences by AdapterRemoval v2 (Schubert et al. 2016), high-quality clean reads that were corrected by SOAPeC v2.01 (Luo et al. 2012) with default settings were initially mapped to plastome of *P. ternata* (KR270823) using BWA (Li and Durbin 2009) and SAMtools (Li and Durbin 2009). The assembly was executed with A5-miseq v20150522 (Coil et al. 2015) and SPAdes v3.9.0 (Bankevich et al. 2012) and resulted in a 164,923 bp scaffold. Subsequently, the plastome annotation was carried out with GeSeq (Tillich et al. 2017) and PGA (Qu et al. 2019). The complete sequence and annotations of *P. peltata* plastome were submitted to GenBank with the accession number MT819952. The sequencing reads are available in the NCBI Sequence Read Archive (SRA) database under the accession number SRR12560323.

The whole chloroplast genome of *P. peltata* was 164,293 bp, consisting of a large single copy region (90,089 bp), a small copy region (24,871 bp), and a pair of inverted repeat regions. One bp indel in *mrna* between two copies located in IRR resulted in 24,881 bp of IRB and 24,982 bp of IRA. The contents of A, T, C, and G are 31.3%, 32.2%, 18.3%, and 18.2%, respectively. In total, 130 genes were identified: 86 coding-protein, 8 rRNA (4 rRNA species), and 36 tRNA genes. Except for 17 genes (all 4 rRNA, 6 tRNA, and 7 protein coding genes) with a double copy, other 96 genes are a single copy. Among these identified genes, 11 single copy genes (*atpF*, *ndhA*, *petB*, *petD*, *rpl16*, *rps16*, *trnG-UCC*, *trnL-UAA*, *trnK-UUU*, *trnV-UAC*) and 5 double-copy genes (*ndhB*, *rpl2*, *ycf68*, *trnA-UGC*, *trnL-GAU*) consist of 2 exons, and 2 single copy genes (*ycf3* and *clpP*) consist three exons. The double copy gene *rps12* share one exon in the LSC region and possess specifically two exons that are located in IR regions.

To validate systematic position of *P. peltata*, 10 species in *Dracunculus* clade of Araceae (Cusimano et al. 2011) were selected to phylogenetic analysis (*Spadipyllum kochii* acted as outgroup). Seventy-eight common protein coding genes (PCGs, without repeat gene) from these plastomes were chosen to further analysis. Coding sequences of all PCGs were aligned using MAFFT v7.450 (Rozewicki et al. 2019) and conserved domains were identified using GBLOCKS 0.91b (Talavera and Castresana 2007) with default parameters. Conserved sequences for all PCGs were then concatenated into a single sequence for each plastome. The phylogenetic relationships among the 10 Araceae species were determined by ML tree and BI tree were made by PhyloSuite v1.2.1 (Zhang et al. 2020). The phylogenetic tree (Figure 1) showed that three species of *Pinellia* and two species of *Arisaema* located in one branch, respectively. These results also
indicated that whole plastome sequences are useful for population genetic and phylogenetic studies of species in Pinellia.

**Disclosure statement**

No potential conflict of interest was reported by the authors.

**Funding**

This study is funded by National Natural Science Foundation of China [31960067 and 31560081].

**Data availability statement**

The data that support the findings of this study will be available in GenBank at https://www.ncbi.nlm.nih.gov/, Accession no. MT819952.
