**Abstract**

**Purpose:** Diabetes causes hyperglycemic disorders due to insufficient activity of insulin, and it also increases blood glucose level. Recent studies have reported the relationship between diabetes and periodontal disease. Periodontitis is advanced by inflammatory cytokines stimulated with LPS. The purpose of this study was to investigate the effects of hyperglycemia on the expression of inflammatory cytokines induced by LPS in osteoblasts.

**Methods:** Cells were cultured for 7 and 14 days in the presence or absence of LPS and glucose. The expression mRNA level of IL-6, RANKL and OCN was determined using real-time PCR. The protein expression of IL-6 and RANKL was also measured using ELISA.

**Results:** LPS and glucose increased the mRNA expression of IL-6, coupled with a decrease in the mRNA expression of OCN, which is associated with IL-6 and glucose. It also increased the protein expression of IL-6 compared to LPS. However, LPS+Glucose did not affect the mRNA and protein expression of RANKL. Furthermore, GLUT4 inhibitor, WZB117, blocked the stimulatory effect of glucose on LPS-induced IL-6 mRNA expression. WZB117 did not affect LPS-reduced OCN mRNA expression.

**Conclusion:** These results suggest that high glucose levels increase LPS-induced IL-6 expression mediated by GLUT4.

**Keywords:** glucose, GLUT4, LPS, proinflammatory cytokine

**Introduction**

The major symptoms of periodontitis, such as gingival inflammation and alveolar bone resorption, are induced by lipopolysaccharide (LPS) [1]. Periodontitis affects nearly 750 million people, which is approximately 10% of global population worldwide [2]. In previous studies, periodontitis and diabetes showed strong evidence that patients with periodontitis had higher levels of hemoglobin A1c (HbA1c) compared to healthy subjects [3,4]. Patients with poorer control of HbA1c at the baseline have been measured using real-time PCR in the manner of the previous study [10]. PCR primer sequences used in real-time PCR are described in Table 1. Target mRNA level was calculated, which was normalized to the mRNA level of beta-actin (β-actin) was used as an internal control.

**Real-time polymerase chain reaction (real-time PCR)**

MC3T3-E1 cells were collected in each condition on days 7 and 14 of culture as a sample. mRNA was isolated from sample and has been reverse transcription to complementary DNA. The target mRNA level was measured using real-time PCR in the manner of the previous study [10]. PCR primer sequences used in real-time PCR are described in Table 1. Target mRNA level was calculated, which was normalized to the mRNA level of beta-actin (β-actin) was used as an internal control.

**Enzyme-linked immunosorbent assay (ELISA)**

The concentrations of IL-6 and RANKL in the cell culture supernatant at 14 days were quantified using ELISA kits (Quantikine; R&D Systems, Minneapolis, MN, USA) in the manner of the previous study [10].

**Statistical analysis**

Data represented the results of three independent experiments. Primary data were confirmed by Shapiro-Wilk test and homoscedasticity by Bartlett test. Differences between groups were analyzed by one-way analysis of variance (ANOVA), and differences were considered statistically significant at P < 0.05. Statistical analysis was performed with EZR software (EZR 1.23; Jichi Medical University Saitama Medical Center, Saitama, Japan) [11]. Each value expressed the mean ± standard division (SD).
Results

The Shapiro-Wilk and Bartlett tests run on the results of the Figs. 1, 2, and 3 showed P values greater than 0.05. Thus, the results of Figs. 1, 2, and 3 were analyzed by one-way ANOVA and Tukey’s multiple comparisons.

Effects of glucose on IL-6 and RANKL mRNA level induced by LPS

LPS and LPS+Glucose significantly increased the mRNA level of IL-6 on days 7 and/or 14 of culture (by 1.31-, 1.90, and 2.80-fold, respectively) compared to that of the untreated control (P = 0.0057: 7 day, P = 0.0000012: 14 day LPS, P = 0.000057: 14 day LPS+Glucose). Additionally, LPS+Glucose significantly increased the mRNA expression of IL-6 compared to that of LPS alone on days 14 of culture (by 1.47-fold, P = 0.000071) (Fig. 1a). However, LPS and LPS+Glucose did not affect the mRNA expression of RANKL (Fig. 1b).

Table 1  PCR primers used in the experiments

| Target  | Primers | GenBank Acc. |
|---------|---------|--------------|
| IL-6    | 5'-CAACGATGATGCACTTGCAGA-3' 5'-CTCCAGGTAGCTATGGTACTCCAGA-3' | NM_031668.1 |
| RANKL   | 5'-CATGGCACCCTGAACTTTGGA-3' 5'-CAAGTCCACCCGCAATGTAC-3' | NM_016133.3 |
| OCN     | 5'-AAACAGAGGGGCAATAAGGT-3' 5'-ACCTGCTAGGAAACGTGACC-3' | NM_007541.2 |
| β-actin | 5'-ATGGAGCCACCAGTCCACA-3' | NM_007393.5 |

Fig. 1  Cells were stimulated with glucose (22 mM) and/or LPS (100 ng/mL) or left unstimulated (untreated control), and the gene expression of IL-6 (a) and RANKL (b) was determined on days 7 and 14 of culture using real-time PCR. *P < 0.05, vs. untreated control, †P < 0.05, vs LPS

Fig. 2  Cells were stimulated with glucose (22 mM) and/or LPS (100 ng/mL) or left without stimulation (untreated control) and the protein expression of IL-6 (a) and RANKL (b) was determined on day 14 of culture using ELISA. *P < 0.05 vs. untreated control, †P < 0.05, vs LPS

Fig. 3  Cells were stimulated with glucose (22 mM), and/or LPS (100 ng/mL) in the presence or absence of GLUT4 inhibitor WZB117 (1.0 μM) or left without stimulation (untreated control) and the gene expression of IL-6 (a) and OCN (b) was determined on days 7 and 14 of culture using real-time PCR. *P < 0.05, vs. untreated control, †P < 0.05, vs LPS+Glucose
Effects of glucose on IL-6 and RANKL protein level induced by LPS
LPS and LPS+Glucose significantly increased the protein expression of IL-6 (by 2.58- and 4.17-fold, respectively) on day 14 of culture compared to that of the untreated control (P = 0.0060: LPS; P = 0.00012: LPS+Glucose) (Fig. 2a). LPS+Glucose also significantly increased the protein expression of IL-6 compared to that of LPS alone (by 1.62-fold, P = 0.0044) (Fig. 2a). Moreover, LPS significantly enhanced the protein expression of RANKL on day 14 of culture compared to that of the untreated control (by 3.46-fold, P = 0.033). However, glucose did not affect the protein expression of RANKL (Fig. 2b).

Effects of GLUT4 antagonist on the mRNA level of IL-6 and OCN
To elucidate the mechanism through which glucose increases LPS-induced IL-6 expression, the present study determined the effect of GLUT4 inhibitor WZB117 on the mRNA expression of IL-6. LPS+Glucose induced the mRNA expression of IL-6 compared to that of the untreated control (by 2.27-fold, P = 0.0052) on day 14 of culture. In contrast, WZB117 inhibited the stimulatory effects of LPS+Glucose on the mRNA expression of IL-6 (by 0.36-fold, P = 0.0021) (Fig. 3a). LPS+Glucose reduced the mRNA expression of OCN on day 14 of culture compared to that of the untreated control (by 0.35-fold, P = 0.043). WZB117 also did not affect LPS-reduced OCN mRNA expression (Fig. 3b).

Discussion
LPS induces the secretion of proinflammatory factors, namely, TNF-α, IL-1, IL-6, and RANKL, and advanced periodontitis [1,9,12]. Proinflammatory cytokines directly affect the periodontal ligament. However, previous studies have shown that these cytokines also stimulate alveolar bone resorption, which involves osteoblasts and osteoclasts [1]. In addition, some previous studies have indicated that IL-6 and C-reactive protein are correlated with type 2 diabetes [13]. Based on these findings, this present study hypothesized that high glucose levels affect the expression of proinflammatory cytokines in osteoblasts. Thus, the purpose of this study was to investigate the effects of glucose on the expression of proinflammatory cytokines induced by LPS in osteoblasts.

Many cell types in inflammatory bone disease secrete IL-6. Previous studies have reported the inhibition of osteoarthritis development in IL-6 knockout mice [14-16]. These findings indicate that IL-6 is a major factor involved in rheumatoid arthritis and plays a direct role in the bone [17]. In contrast, IL-6 also binds to its soluble receptor, activating osteoblast differentiation in vitro [18,19]. However, IL-6 does not affect osteoblast proliferation [20].

RANKL, a member of the TNF superfamily, is a transmembrane ligand expressed by osteoblasts [21,22]. RANKL strongly induces osteoclast differentiation and survival. It is also expressed on stromal, B-lymphoid lineage, and activated T-cells [21]. Furthermore, soluble RANKL is secreted by various cells [21-23]. Receptor activator of nuclear factor kappa B in the monocyte-macrophage lineage cells bind to RANKL and differentiate from precursor cells to mature osteoclasts that have the ability of bone resorption [24]. RANKL knockout mice exhibit a complete lack of osteoclasts, which causes severe osteoporosis [25]. In contrast, RANKL transgenic mice reduce bone mass by increasing the number of osteoclasts [26]. These studies indicate that IL-6 and RANKL are major factors for bone resorption-implicated inflammation in osteoarthritis and periodontitis. The current study showed that glucose increased the LPS-induced expression of IL-6, whereas glucose did not affect LPS-induced RANKL expression (Figs. 1 and 2). However, previous studies have revealed that IL-6 induces the production of RANKL, associated with indirect osteoclastogenesis [27]. Thus, the results of this study suggest that LPS+Glucose-induced expression of IL-6 might stimulate osteoclastogenesis.

A family of GLUT isomers mediates cellular glucose uptake. These isomers have the following three high-affinity transporters: GLUT1, which is expressed in various tissues including tumors; GLUT3, which is expressed particularly in brains (neurons); and GLUT4, which is expressed in insulin-sensitive tissues such as striated muscle and adipose tissue [28]. GLUT1, GLUT3, and GLUT4 are expressed in osteoblasts in vitro. However, GLUT1 and GLUT3 are constantly expressed during the course of osteoblast differentiation [29]. GLUT4 expression is implicated in the enhancement of insulin-stimulated glucose uptake [29]. Downregulation of GLUT4 expression eliminates insulin-stimulated glucose uptake in osteoblasts in vitro and reduces osteoblast proliferation and differentiation. Furthermore, GLUT4 is expressed in osteoblasts, osteocytes, and chondrocytes, similar to that of the adjacent skeletal muscles, in vivo [29]. Next, this study focused on the effect of GLUT4 on the expression of IL-6 induced by the stimulation of LPS under high glucose concentrations in the present study. GLUT4 inhibitor WZB117 blocked the stimulatory effects of LPS and glucose on IL-6 mRNA expression on day 14 of culture (Fig. 3a). These results showed that glucose enhanced LPS-induced expression of IL-6 through GLUT4 in osteoblasts.

A previous study has reported that the plasma concentration of IL-6 and glucose increases after orthopedic surgery, whereas the plasma concentration of OCN decreases [30]. In a previous study, 108 patients with type 2 diabetes exhibited increased plasma IL-6 levels and decreased plasma OCN levels compared to those for non-diabetic controls. These results revealed that inflammation might be correlated with hyperglycemia and OCN expression [9,30]. The plantaris and soleus muscle injection of IL-6 induces GLUT4 expression in mice in vivo [31]. IL-6 also enhances GLUT4 expression in C2C12 cells that differentiate in vitro. In contrast, OCN inhibits TNF-α, IL-6, and IL-1β expression and increases GLUT4 expression in adipocytes [32]. TNF-α stimulation also enhances IL-6 mRNA expression and lowers OCN mRNA expression in osteoblasts. However, the expression of GLUT4 does not affect OCN in bone tissue in vivo and in vitro [32]. These conflicting observations showed the expression of GLUT4 independently in each tissue. Additionally, the expression of GLUT4 may also cause a difference in the physiological activation is a conceivable possibility. The present study showed that stimulation of LPS under high glucose levels reduced OCN mRNA expression. GLUT4 inhibitor did not affect the mRNA expression of OCN in osteoblasts stimulated with LPS under high glucose levels (Fig. 3b). These results showed that GLUT4 was not associated with a decrease in OCN expression by glucose and LPS. Thus, in future studies, it will be necessary to investigate the relationship between insulin effects and OCN expression to elucidate the mechanism underlying inflammation and hyperglycemia in osteoblasts. In summary, high glucose levels increased LPS-induced IL-6 and IL-1α expression mediated by GLUT4. However, GLUT4 did not decrease OCN expression in osteoblasts. Glucose did not exert a stimulatory effect on the LPS-induced protein expression of RANKL. These phenomena might be related to the mechanism underlying the relationship between periodontitis and type 2 diabetes in vitro. To the best of this knowledge, this is the first study to show that GLUT4 mediates IL-6 expression under high glucose levels in osteoblasts.
