A new supersymmetric approach to the analysis of dynamical symmetries for matrix quantum systems is presented. Contrary to standard one-dimensional quantum mechanics where there is no role for an additional symmetry due to nondegeneracy, matrix hamiltonians allow for non-trivial residual symmetries. This approach is based on a generalization of the intertwining relations familiar in SUSY Quantum Mechanics. The corresponding matrix supercharges, of first or of second order in derivatives, lead to an algebra which incorporates an additional block diagonal differential matrix operator (referred to as a "hidden" symmetry operator) found to commute with the superhamiltonian. We discuss some physical interpretations of such dynamical systems in terms of spin $1/2$ particle in a magnetic field or in terms of coupled channel problem. Particular attention is paid to the case of transparent matrix potentials.
1. Introduction

Supersymmetric Quantum Mechanics (SUSY QM) [1] is an interesting framework to analyze non-relativistic quantum problems. In particular it allows to investigate the spectral properties of certain quantum models as well as to generate new systems with given spectral characteristics.

In general it is well known that SUSY algebra provides the relation between (super)partner hamiltonians (which are often referred as "bosonic" and "fermionic") associated to a two-fold degeneracy of levels.

Much less attention has been paid in the literature to the possibility of using SUSY as a tool to study individual ("internal") symmetries of each superpartner hamiltonian. In principle this can be useful if it allows to integrate partially dynamical systems by discovering an additional dynamical symmetry which we shall refer to as a "hidden" symmetry. We will show that indeed hidden symmetries may be revealed by SUSY inspired approaches [1].

The standard SUSY QM relations read

\[
\{Q^+, Q^-\} = H = \begin{pmatrix} h^{(1)} & 0 \\ 0 & h^{(2)} \end{pmatrix} = \begin{pmatrix} q^+q^- & 0 \\ 0 & q^-q^+ \end{pmatrix};
\]

\[
h^{(i)} \equiv -\partial^2 + V^{(i)}(x); \quad q^\pm = \mp \partial + W(x); \quad \partial \equiv \partial/\partial x;
\]

\[
Q^- = \begin{pmatrix} 0 & 0 \\ q^- & 0 \end{pmatrix} \quad Q^+ = \begin{pmatrix} 0 & q^+ \\ 0 & 0 \end{pmatrix},
\]

\[
\{Q^\pm, Q^\pm\} = 0.
\]

\[
\{Q^\pm, H\} = 0; \quad h^{(1)} q^+ = q^+ h^{(2)}
\]

In general there are different realizations of this algebra, e.g. multidimensional [2] and matrix ones [3]. It is also possible to generalize the algebra itself by preserving Eqs. (3), (4) and allowing, by a non standard form of the intertwining operators \(q^\pm\), to modify (1) to become

\[
\{Q^+, Q^-\} = K = \begin{pmatrix} k^{(1)} & 0 \\ 0 & k^{(2)} \end{pmatrix} = \begin{pmatrix} q^+q^- & 0 \\ 0 & q^-q^+ \end{pmatrix},
\]

where the diagonal operator \(K\) is no more the superhamiltonian but has in general the nature of a symmetry operator

\[
[k^{(i)}, h^{(i)}] = 0.
\]

\(^d\)Notice that the existence of a symmetry operator is not necessarily associated with degeneracy of eigenstates of the Hamiltonian. One can convince oneself of this fact for matrix Quantum Mechanics taking \(2 \times 2\) diagonal hamiltonian with components having different spectra and no degeneracy. In this case a symmetry operator is obviously \(\sigma_3\) playing the role of a grading operator.
This generalization was already discussed for 1-dim \[4\] and 2-dim \[5\] Quantum Mechanics. For 1-dim systems and intertwining operators of second order in derivatives the only relevant case was the one for which \(K\) is a function of \(H\),

\[
K = H^2 - 2\alpha H + \beta
\]

where \(\alpha\) and \(\beta\) are constants. For the 2-dim case there exists the possibility of having a central charge \(R\), which commutes with all elements of algebra, such that

\[
K = f(H) + R. \tag{7}
\]

A new, supersymmetrical, method was elaborated \[4\], \[5\] to investigate hidden dynamical symmetries of quantum systems. The existence of such a differential operator \(R\) implies a dynamical symmetry (unknown a priori) made apparent by the generalized SUSY algebra.

Let us remind the physical impact of the supersymmetric approach to the Dirac equation \[6\] with some applications to superconductivity \[7\], to pseudorelativistic behaviour of electrons in two-band systems \[8\] and to attempts to a diagonalization procedure \[3\]) in nuclear and atomic physics coupled channel problems and finally in the treatment of particles with spin in an external magnetic fields \[9\]. Therefore it is important to discuss the role of symmetry operators for 1-dim dynamical systems of Schrödinger type with matrix potentials. Formally the most straightforward method is to study the commutator of the Hamiltonian matrix with a generic differential operator matrix \(R\) and solve the corresponding system of differential equations obtained by imposing the commutator to vanish \([h, R] = 0\). Incidentally one can easily check that for the scalar case this system of equations (after possible subtraction of the Hamiltonian) does not allow for non-trivial solution. On the contrary in the matrix case non-trivial solutions exist even for the case of symmetry operators of first order in derivatives. For higher order derivatives the equations become rather cumbersome and it is too difficult to provide the general discussion of the solutions.

For this higher order case a method of solution suggested by supersymmetry seems to be useful. It starts from the same idea of factorization originally proposed by Schrödinger \[10\] with the related intertwining operators (see \[4\]) but now it is not applied to the Hamiltonian but rather to the symmetry operator: this method reduces the order of differential equations one must solve without however increasing their number. In this paper we shall find non-trivial genuine second order operators \(R\) even for 1-dim first order intertwining matrix operators.

The paper is organized as follows. In Section 2 we shall investigate the SUSY approach with intertwining operators of first order in derivatives. A variety of matrix systems allowing for the genuine second order symmetry operators will be obtained. In the Section 3 this method will be applied to a more complex case of higher order
Matrix Hamiltonians,

intertwining operators, examining in particular the conditions for the factorizability of these intertwining operators (reducibility). The type of physical systems which we can describe in our formalism include a particle with magnetic moment in a magnetic field and more generally a class of systems with one continuous and one discrete degrees of freedom. A novel construction is given for transparent matrix potentials which are not duplications of standard scalar transparent potentials and are not generated by iterations of first order Darboux transformations.

2. First order Matrix SUSY Quantum Mechanics

We start from the general first order (in derivatives) representation of the components of supercharges in the case of 1-dim Quantum Mechanics

\[ q^+ \equiv A \partial + \tilde{B}; \quad q^- \equiv -A^\dagger \partial + \tilde{B}^\dagger, \]

where \( A \) and \( \tilde{B} \) are matrices. Imposing that these operators intertwine the Hamiltonians \( h^{(1)} \) and \( h^{(2)} \) (see Eq.(4)) reads

\[ (-\partial^2 + V^{(1)}(x))(A \partial + \tilde{B}) = (A \partial + \tilde{B})(-\partial^2 + V^{(2)}(x)), \]

where \( V^{(1)}, V^{(2)} \) are hermitean potential matrices. Eq.(9) amounts to solve the following three equations:

\[ A' = 0; \]

\[ V^{(1)} A - A V^{(2)} = 2 \tilde{B}'; \]

\[ -\tilde{B}'' + V^{(1)} \tilde{B} - \tilde{B} V^{(2)} - A V^{(2)'} = 0. \]

The first equation implies that from now on we will assume \( A \) to be a constant matrix. As usual in the frameworks of SUSY QM the intertwining relations Eq.(8) lead to the connection between the column eigenfunctions of Hamiltonians \( h^{(1)} \) and \( h^{(2)} \):

\[ \Psi^{(1)}(x) = (A \partial + \tilde{B})\Psi^{(2)}(x); \quad \Psi^{(2)}(x) = (A \partial + \tilde{B})^\dagger\Psi^{(1)}(x) \]

The Eq.(13) allows sometimes for zero-modes, and the spectra of the partner hamiltonian coincide up to these zero-modes.

What is not standard is the fact that Eq.(14) does not hold because the products of the supercharge components are no more equal to the Hamiltonians:

\[ q^+ q^- = k^{(1)} = -A A^\dagger \partial^2 + (A \tilde{B}^\dagger - \tilde{B} A^\dagger) \partial + \tilde{B} \tilde{B}^\dagger + A \tilde{B}'; \]

\[ q^- q^+ = k^{(2)} = -A^\dagger A \partial^2 + (\tilde{B}^\dagger A - A^\dagger \tilde{B}) \partial + \tilde{B}^\dagger \tilde{B} - A^\dagger \tilde{B}'. \]
It is natural to consider separately $\det A \neq 0$ and $\det A = 0$ because the way to solve the system of equations (10), (11), (12) differs for the two cases. In the case $\det A \neq 0$ it is possible to subtract the Hamiltonians $h^{(1)}$ and $h^{(2)}$ from $k^{(1)}$ and $k^{(2)}$, being left with a symmetry operators of first order in derivatives; otherwise we deal with second order operators. Furthermore by a suitable similarity transformation induced by the matrix $A$ itself it is possible to consider $A = -1$ as a representative of the case $\det A \neq 0$ whereas we can take the matrix $A = \begin{pmatrix} a & b \\ 0 & 0 \end{pmatrix}$ as representative of $\det A = 0$.

2.1. The case $A = -1$, symmetry operators of first order

In this case Eqs. (11) and (12) become

$$V^{(2)} - V^{(1)} = 2\tilde{B}';$$

$$-\tilde{B}'' + V^{(1)}\tilde{B} - \tilde{B}V^{(2)} + V^{(2)'} = 0.$$  (17)

One can parametrize the potential matrices taking into account (16):

$$V^{(1)} = \tilde{B}^2 - \tilde{B}' + W; \quad V^{(2)} = \tilde{B}^2 + \tilde{B}' + W.$$  (18)

Then Eq. (17) becomes simply

$$W'(x) = [\tilde{B}(x), W(x)].$$  (19)

Whoever is familiar with ordered products, e.g. in Gauge Field Theory, will not have difficulty to recognize that Eq. (19) has not a simple local solution unless

$$[\tilde{B}(x), \tilde{B}(y)] = 0.$$  (20)

Since effectively this last condition reduces the matrix problem to a scalar problem we do not find this case of any interest for us.

From (16) one deduces that the non-hermitean part of $\tilde{B}$ does not depend on $x$ because of the hermiticity of the potentials. Therefore we can parametrize $\tilde{B}(x) = B(x) + iC$, where $B$ and $C$ are both hermitean matrices and $C$ is a constant matrix. Correspondingly one has to solve the system of matrix equations

$$W' = [B, W] + i[C, W];$$  (20)

$$W - W^\dagger = -2i\{B, C\}.$$  (21)
Matrix Hamiltonians... 

which are the consequence of (17) and of the hermiticity of both potentials. Restricting to $2 \times 2$ matrix potentials one can study the system of equations (20) and (21) by expanding all matrices in Pauli matrices and unity:

$$B = b_0 + b_i \sigma_i; \quad C = c_0 + c_i \sigma_i; \quad W = w_0 + w_i \sigma_i,$$

with components $b_0, b_i$ and $c_0, c_i$ real. The related symmetry operators read:

$$R^{(1)} = q^+ q^- - h^{(1)} = 2i C \partial + 2C^2 - 2iBC - W;$$  

$$R^{(2)} = q^- q^+ - h^{(2)} = 2i C \partial + 2C^2 - 2iCB + W.$$  

While it is not restrictive to set $c_1 = c_2 = 0$, it is not interesting to choose also $c_3$ and $c_0$ both to vanish. Indeed in this case the symmetry operators above are no more differential operators and become proportional to a constant matrix $W$.

A general solution of the nonlinear system of matrix equations (20), (21) amounts first to find a solution of the subsystem:

$$Imw_0 = -2(b_0 c_0 + b_3 c_3);$$

$$Imw_1 = -2b_1 c_0;$$

$$Imw_2 = -2b_2 c_0;$$

$$Imw_3 = -2(b_3 c_0 + b_0 c_3);$$

$$w_0 = \text{const};$$

$$Rew_3 = \text{const},$$

however a complete solution of (21), (21) cannot be written. Particular solutions of (21) and (21) in terms of the components (22) can be obtained by making specific ansätze:

1) Let us assume

$$c_0 = b_3 = Rew_3 = 0; \quad Imw_3(x) \equiv 0; \quad c_3 \neq 0,$$

$b_3 \neq 0$ would correspond to a trivial solution $W(x) = \text{Const.}$ Then one obtains

$$b_0 = 0, \quad Rew_1 = \beta \cos(2c_3 x), \quad Rew_2 = -\beta \sin(2c_3 x), \quad b_2(x) = -b_1(x) \tan(2c_3 x),$$

where $\beta$ is a constant parameter and $b_1(x) \equiv \bar{b}_1(x) \cos(2c_3 x)$ with $\bar{b}_1(x)$ being an arbitrary nonsingular function. Correspondingly the potentials read

$$V^{(1),(2)}(x) = \bar{b}_1^2(x) - c_3^2 + Rew_0$$

$$+ \ [\beta \cos(2c_3 x) \mp \bar{b}_1(x) \cos(2c_3 x) \pm 2c_3 \bar{b}_1 \sin(2c_3 x)] \cdot \sigma_1$$

$$- \ [\beta \sin(2c_3 x) \mp \bar{b}_1(x) \sin(2c_3 x) \mp 2c_3 \bar{b}_1(x) \cos(2c_3 x)] \cdot \sigma_2$$  (25)
and the symmetry operators (23), (24) after subtraction of constants become:

$$R^{(1),(2)} = i\sigma_3 \partial \mp [\tilde{b}_1(x) \sin(2c_3x) + \frac{\beta}{2c_3} \cos(2c_3x)] \cdot \sigma_1 \pm [\tilde{b}_1(x) \cos(2c_3x) - \frac{\beta}{2c_3} \sin(2c_3x)] \cdot \sigma_2.$$  

Among the different interpretations concerning the physics of the matrix potentials $V^{(1),(2)}$ one consists of a spin 1/2 neutral particle in a (inhomogeneous) magnetic field. It is necessary to assume that the magnetic field depends only on the coordinate $x \equiv x_3$ and lies in the $(x_1, x_2)$ plane in order to ensure the vanishing of its divergence $\partial_i B_i = 0$. While the motion in the $(x_1, x_2)$ plane is trivially free the dynamics is still rather interesting because of the $x_3$ motion [9]. Physicswise the inhomogeneity of the magnetic field is determined in this case by the requirement of vanishing of the scalar potential in (25) (neutrality of the particle).

2) Let us assume $c_0 = b_3 = Rew_3 = 0; \quad Imw_3(x) \neq 0 \quad c_3 \neq 0$, as before $b_3 \neq 0$ would correspond to a trivial solution $W(x) = \text{Const}$. Then one obtains

$$b_0(x) = -\frac{1}{2c_3} Imw_3(x); \quad b_1(x) = \frac{(Rew_2)' + 2c_3 Rew_1}{2Imw_3}, \quad b_2(x) = -\frac{(Rew_1)' + 2c_3 Rew_2}{2Imw_3},$$

where

$$Rew_1(x) = \sqrt{(Imw_3)^2 + \beta \cos f(x)} = \sqrt{(2b_0c_3)^2 + \beta \cos f(x)},$$

$$Rew_2(x) = \sqrt{(Imw_3)^2 + \beta \sin f(x)} = \sqrt{(2b_0c_3)^2 + \beta \sin f(x)}.$$  

$\beta$ is a constant parameter as well as $c_3$ and $f(x)$ and $Imw_3(x)$ are arbitrary functions. The potentials and the symmetry operators read:

$$V^{(1),(2)}(x) = b_0^2 \mp b_0' + b_1^2 + b_2^2 - c_3^2 + Rew_0 + [2b_0b_1 + Rew_1 \mp b_1'] \cdot \sigma_1 + [2b_0b_2 + Rew_2 \mp b_2'] \cdot \sigma_2$$  

$$R^{(1),(2)} = i\sigma_3 \partial \pm \left[\frac{Rew_1}{2c_3}\right] \cdot \sigma_1 \pm \left[-b_1(x) - \frac{Rew_2}{2c_3}\right] \cdot \sigma_2.$$  

In terms of the “magnetic” interpretation given above one can now notice that the absence of the scalar potential in (27) is less restrictive because the magnetic field still depends on one arbitrary function. The intrinsic ”periodicity” of the magnetic field forces a similar periodicity of the wave function. We warn however not to interpret the periodicity too naively since it depends in general on the properties of the arbitrary function $f(x)$, e.g. asymptotically constant magnetic field can be incorporated in this scheme.
One can also find solutions for other ansätze like e.g.  
\[ c_0 = 0, \; c_3 \neq 0, \; Rew_3 = \text{const} \neq 0, \]
similarly to 1), 2).

2.2. The case \( \det A = 0 \), the symmetry operators of second order

The constant (see (10)) matrix \( A \) has now the form
\[
A = \begin{pmatrix} a & b \\ 0 & 0 \end{pmatrix}
\]  
(29)

We write the matrices \( V^{(1),(2)} \) and \( B \) explicitly and for simplicity we assume them to be real:
\[
V^{(i)} = \begin{pmatrix} v^{(i)}_1 & v^{(i)}_2 \\ v^{(i)}_3 & v^{(i)}_4 \end{pmatrix}
\]  
(30)
\[
B(x) = \begin{pmatrix} b_1 & b_2 \\ b_3 & b_4 \end{pmatrix}
\]  
(31)

Equations (11) and (12) can be solved and the potentials can be written in a similar way as before in terms of Pauli matrices, however the reality condition forces the absence of a \( \sigma_2 \) term \( e \). The hidden symmetry operators are now of second order in derivatives.

In the case \( b \neq 0 \) it is possible to find several solutions dependent on arbitrary functions; in the case \( b = 0, \; a = 1 \) the form of the solutions simplifies. One solution is given by:
\[
v^{(1)}_1(x) = b'_1 + b'^2 + c^2 b^{-2} + c_1; \quad v^{(1)}(x) = -2cb'_2 b'^{-2}; \\
v^{(1)}_2(x) = -\left(\frac{b'_2}{b_2}\right) + \left(\frac{b'^2}{b_2}\right)^2 + \frac{2b'_1 b_2}{b_2} + b'^2 + b^{-2} + \frac{c^2}{b_2} - b'_1 + \tilde{c}_1; \\
v^{(2)}_1(x) = -b'_1 + b'^2 + \frac{c^2}{b_2} + c_1; \quad v^{(2)}(x) = -2b'_2; \\
v^{(2)}_2(x) = \frac{b''}{b_2} + \frac{2b'_1 b_2}{b_2} + b'^2 + b^{-2} + \frac{c^2}{b_2} - b'_1 + \tilde{c}_1
\]  
(32)

where \( b_1(x), b_2(x) \) are arbitrary functions, \( b_3(x) = c \cdot b^{-1}_2(x) \) and \( b_4 = 0 \). The symmetry operators \( R^{(1),(2)} \) can be straightforwardly derived according to (14), (13) and are second order differential operators.

\[ ^e \text{The interpretation of the dynamics as a magnetic interaction of } s = 1/2 \text{ particle is now still possible but we can also consider it as a coupled channel problem as discussed in [3].} \]
For the second solution $v_1^{(1),(2)}(x)$ and $v^{(1),(2)}(x)$ are the same as in (32) and

$$v_2^{(1)}(x) = \frac{b_3'}{b_3} - \frac{2b_3' b_1}{b_3} - \frac{2b_3' b_4}{b_3} - b_1' + \sum_{k=1}^{4} b_k' + \tilde{c}_1;$$

$$v_2^{(2)}(x) = \frac{b_2'}{b_2} + \frac{2b_2' b_1}{b_2} + \frac{2b_3' b_4}{b_2} + b_4' + \sum_{k=1}^{4} b_k'^2 + \tilde{c}_1,$$

where $b_2(x), b_3(x)$ are arbitrary functions such that $b_2 \cdot b_3 \neq 0$, $b_4 = const \neq 0$ and

$$b_1(x) = (b_2 b_3)^{-1} \left[ \frac{(b_2 b_3)^2}{2b_4} - (2b_4)^{-1}(b_2^2 + b_3^2) + \alpha \right]$$

with $\alpha$ a constant parameter.

3. Second order Matrix SUSY Quantum Mechanics

Let us define the second order differential operators

$$q^+ = (q^-)^\dagger = \partial^2 - 2F(x)\partial + B(x).$$

$$q^- = (q^+)^\dagger = \partial^2 + 2F^\dagger(x)\partial + B^\dagger(x) + 2F'^\dagger(x).$$

where $F(x)$ and $B(x)$ are $2 \times 2$ matrices. This representation for $q^\pm$ can be inserted into (2) — (3).

The intertwining relations are equivalent to a system of three non-linear matrix differential equations:

$$V^{(1)} - V^{(2)} + 4F' = 0$$

$$F'' - V^{(1)}F + FV^{(2)} - B' - V^{(2)'} = 0$$

$$B'' + V^{(2)''} - V^{(1)}B + BV^{(2)} - 2FV^{(2)'} = 0$$

Our attitude towards the solution of this system of equations is that we consider $q^\pm, h^{(2)}, h^{(1)}$ to be essentially unknown except for Schrödinger form of Hamiltonians and assumption of structure (33) of the supercharges, so the problem is to find the solution in terms of the matrices $F(x), B(x), V^{(i)}(x)$.

Due to the complexity of the problem (matrix, 2nd derivatives, non-linearity) it does not seem realistic to search for a general solution in analytic form, instead we believe that techniques of Higher Order SUSY QM as developed in [4] can provide a useful tool for solving in an "indirect" way by the ansatz of factorizability of $q^\pm$, i.e. restricting to the reducible matrix Higher Order SUSY QM.
Another possibility which we mention is a particular solution for which the terms $FV^{(2)} - V^{(1)}F$ appearing in Eq. (36) reduce to $\{F, F\}$ with the aim of a "direct" integration of this equation. A sufficient condition which allows this integration is

$$V^{(1)} + V^{(2)} = 2P(F)$$

where $P$ is an arbitrary "scalar" function of the matrix $F(x)$ like for example $P = \Sigma c_n(x)F^n(x)$ where $c_n$ are scalar functions.

### 3.1. Reducible Higher Order Matrix SUSY QM

A specific ansatz consists in the factorizability of the operators $q^\pm$ of (33), (34) in terms of ordinary superpotentials $W(x)$ and $\tilde{W}(x)$:

$$q^+ = q^+_1 q^+_2 = (-\partial + W(x)) (-\partial + \tilde{W}(x)),$$

connected by the ladder equation

$$q^- q^+ = q^+_2 q^-_2 + \hat{\Delta} \quad \text{or} \quad W' + W^2 = -\tilde{W}' + \tilde{W}^2 + \hat{\Delta},$$

with $\hat{\Delta}$ a constant hermitean matrix as will be clear later on. Let us assume furthermore $\hat{\Delta}$ to be diagonal\(^\dagger\). Then $F$ and $B$ of Eqs.(33), (34) are determined by the superpotentials $W(x), \tilde{W}(x)$:

$$2F = W + \tilde{W}, \quad B = W\tilde{W} - \tilde{W}'$$

The factorization Eq.(38) arises from two successive standard SUSY QM transformations

$$\left( \begin{array}{cc} h^{(1)} & 0 \\ 0 & h \end{array} \right) = \left( \begin{array}{cc} q^+_1 q^-_1 & 0 \\ 0 & q^-_1 q^+_1 \end{array} \right)$$

and

$$\left( \begin{array}{cc} h & 0 \\ 0 & h^{(2)} + \hat{\Delta} \end{array} \right) = \left( \begin{array}{cc} q^+_2 q^-_2 + \hat{\Delta} & 0 \\ 0 & q^-_2 q^+_2 + \hat{\Delta} \end{array} \right)$$

by deleting the "intermediate" hamiltonian:

$$H = \left( \begin{array}{cc} q^+_1 q^-_1 & 0 \\ 0 & q^-_2 q^+_2 + \hat{\Delta} \end{array} \right).$$

The matrix $\hat{\Delta}$ has to be such that $[H, Q^\pm] = 0$ and consequently $[q^\pm_2, \hat{\Delta}] = 0$ which makes clear the reason why $\hat{\Delta}$ has to be constant and that $[\tilde{W}, \hat{\Delta}] = 0$. We

\(^\dagger\) If it is not it can be diagonalized by a constant unitary transformation which also affects other operators.
therefore can conclude that \([h^{(2)} + \hat{\Delta}, \hat{\Delta}] = 0\) and this allows us to identify \(R^{(2)} \equiv \hat{\Delta}\) as a symmetry operator for \(h^{(2)}\). If it further commutes with \(h^{(1)}\) this operator is such that

\[
\{Q^+, Q^-\} = (H)^2 - \hat{\Gamma} \cdot H
\]

where \(\Gamma\) is a block diagonal matrix

\[
\Gamma \equiv \begin{pmatrix} \hat{\Delta} & 0 \\ 0 & \hat{\Delta} \end{pmatrix}
\]

and thus it corresponds to a rather "trivial" \(R\) operator. We shall from now on exclude such a case imposing that the operator

\[
R^{(1)} = -q_1^+ \hat{\Delta} q_1^-
\]

be non-trivial\(^9\). The last case is rather interesting because it incorporates the possibility of having genuine partner symmetry operators of different orders in the derivatives.

In order to derive a solution we expand the previous operators in terms of Pauli matrices:

\[
W(x) = w_0 + w_1 \sigma_1; \quad \bar{W}(x) = \bar{w}_0 + \bar{w}_1 \sigma_1; \quad \hat{\Delta} = \delta_0 + \delta_3 \sigma_3; \quad \delta_3 \neq 0.
\]

To illustrate the techniques involved we give now an example:

**Example 1.** \(\delta_0 = 0; \quad w_0(x) = \bar{w}_0(x); \quad w_2(x) = 0\)

Eq. (39) takes then the form

\[
\begin{align*}
2w_0w_3 + w_3' - 2w_0\bar{w}_3 + \bar{w}_3' - \delta_3 &= 0, \\
2w_0w_1 + w_1' &= 0, \\
w_3^2 + w_1^2 + 2w_0' - \bar{w}_3^2 &= 0
\end{align*}
\]

with the following solution

\[
w_0 = \bar{w}_0 = 1/(2x), \quad w_1 = 1/x, \quad w_3 = \bar{w}_3 = \delta_3 x/2.
\]

In order to arrive to an interpretation of these results we have to write the potentials:

\[
\begin{align*}
V^{(1)}(x) &= W^2 - W' = 7/4x^2 + \delta_3^2 x^2/4 + (2/x^2) \cdot \sigma_1; \\
V^{(2)}(x) &= W^2 + W' + \hat{\Delta} = -1/(4x^2) + \delta_3^2 x^2/4 + 2\delta_3 \cdot \sigma_3.
\end{align*}
\]

\(^9\)In the concluding Section of \cite{2} Eq. (46) first appeared.
e.g. eigensolutions. These potentials contain centrifugal singularities and therefore we pose the eigenvalue problem on the semiaxis \( x > 0 \). The physical solutions \( L_2 \)-normalizable at the origin have the following behaviour:

\[
\Psi^{(1)}(x) \sim \begin{pmatrix} a_1 x^{5/2} + a_2 x^{1/2} \\ a_1 x^{5/2} - a_2 x^{1/2} \end{pmatrix} ; \quad \Psi^{(2)}(x) \sim \begin{pmatrix} b_1 x^{1/2} \\ b_2 x^{1/2} \end{pmatrix} ,
\]

where we display explicitly the diagonalization of matrix potential \( V^{(1)}(x) \). Both potentials for \( \delta_3 \neq 0 \) lead to a discrete spectrum.

The symmetry operator \( R^{(1)} \) can be calculated from Eq. (46) and found to contain also \( \sigma_2 \) type of terms: it can be written as

\[
R^{(1)} = \sigma_3 \partial^2 + (2i/x) \sigma_2 \partial + \{-\delta_3 \cdot \sigma_1 - (i/x^2) \cdot \sigma_2 + [1/(4x^2) - \delta_3^2 x^2/4] \cdot \sigma_3 \}.
\]

This operator also contains centrifugal singularities but one can easily prove that it maps \( L_2 \)-normalizable solutions (52) into themselves. Therefore it is a true symmetry operator. The partner symmetry operator \( R^{(2)} = \delta_3 \sigma_3 \) is regular.

As in Subsection 2.1, also this example allows an interpretation in terms of the external field as a magnetic field. It is possible to consider a magnetic field as a (pseudo)vector in a plane orthogonal to the one dimensional axis in which the particle is allowed to move \( x \equiv x_2 \). Contrary to Subsection 2.1, the magnetic field in \( V^{(2)} \) is homogeneous along the \( x_3 \) axis, while in \( V^{(1)} \) it is not homogeneous (depends on \( x_2 \)) and has non zero components in the \((x_1, x_3)\) plane.

To describe other examples it is useful to introduce

\[
W(x) + \tilde{W}(x) \equiv 2F(x) = 2f_0 + 2f_1 \sigma_i; \quad 2f_1 = w_1, \quad 2f_2 = w_2
\]

(39) becomes:

\[
2F' - 4F^2 + 2\{F, W\} = \hat{\Delta}.
\]

The problem is now expressed in terms of a matrix non-linear differential equation (54) for \( F, W \). Since we are unable to present a general (analytic) discussion we provide particular solutions of the system (54) which in terms of components can be rewritten:

\[
2f_0' - 4(f_0)^2 + 4(f_1)^2 + 4(f_2)^2 - 4(f_3)^2 + 4f_0 w_0 + 4f_3 w_3 = \delta_0; \quad (55)
\]

\[
f_1' + 2w_0 f_1 = 0; \quad (56)
\]

\[
f_2' + 2w_0 f_2 = 0; \quad (57)
\]

\[ ^{k}\text{This choice will allow to implement the condition of absence of sources of magnetic field automatically, } \partial_i B_i = 0. \]
Matrix Hamiltonians...

\[ 2f_3' - 8f_0f_3 + 4f_0w_3 + 4w_0f_3 = \delta_3. \] (58)

The solutions presented in the following will allow to construct explicitly the partner potentials and the symmetry operators by making use of the general expressions in terms only of the \( f_k \), \( (k = 0, 1, 2, 3) \) and \( w_0, w_3 \):

\[ V^{(1)}(x) = w_0^2 + w_3^2 - w_0' + 4(f_1^2 + f_2^2) - 4f_1' \cdot \sigma_1 - 4f_2' \cdot \sigma_2 + (2w_0w_3 - w_3') \cdot \sigma_3; \]

\[ V^{(2)}(x) = w_0^2 + w_3^2 - w_0' + 4(f_1^2 + f_2^2 + f_0') - \delta_0 + [2w_0w_3 - w_3' + 8(2f_0f_3 - f_0w_3 - f_3w_0) + \delta_3] \cdot \sigma_3. \]

It is advantageous to use not the expression (46) directly but to define a symmetry operator by suitable subtraction and rescaling (see Section 1):

\[ \tilde{R}^{(1)} \equiv -\frac{R^{(1)} + \delta_0 h^{(1)}}{\delta_3} = -\sigma_3 \partial^2 + 4i(f_2\sigma_1 - f_1\sigma_2)\partial + (2w_0w_3 - w_3') + 4(w_3f_1 - iw_0f_2) \cdot \sigma_1 + 4(w_3f_2 + iw_0f_1) \cdot \sigma_2 + (w_0^2 + w_3^2 - 4f_1^2 - 4f_2^2 - w_0') \cdot \sigma_3, \]

and we remind that \( R^{(2)} \equiv \hat{\Delta} \).

We now list two particular cases:

Example 2. \( f_0 \equiv 0; \ f_3 \not\equiv 0 \)

The solution is of the type

\[ 2f_1(x) = \gamma_1 \exp(-2 \int w_0 dx); \]
\[ 2f_2(x) = \gamma_2 \exp(-2 \int w_0 dx); \]
\[ 2f_3(x) = \exp(-2 \int w_0 dx) \left[ \gamma_3 + \delta_3 \exp(+2 \int w_0 dx) \right]; \]
\[ w_3(x) = (4f_3)^{-1} \left[ \delta_0 - (\gamma_1^2 + \gamma_2^2) \exp(+4 \int w_0 dx) + 4f_3^2 \right] \]

Example 3. \( f_3 \equiv 0; \ f_0 \not\equiv 0 \ \delta_0 = 0 \)

The solution of the Eqs. (55) — (58) can be written as

\[ 2f_1(x) = \gamma_1 \exp(-2 \int w_0 dx); \]
\[ 2f_2(x) = \gamma_2 \exp(-2 \int w_0 dx); \]
\[ w_3(x) = \delta_3/(4f_0); \]
\[ f_0(x) = 1/2\sqrt{\gamma_1^2 + \gamma_2^2} \exp(-2 \int w_0 dx) \tanh(-\sqrt{\gamma_1^2 + \gamma_2^2} \int \exp(-2 \int w_0 dx) + C). \]
3.2. Transparent matrix potentials

We now explore a physical case for which the Hamiltonian $H^{(2)}$ describes free motion; in Eqs. (35), (36), (37) we assume $V^{(2)} = 0$ and, as a consequence of SUSY, $V^{(1)}$ becomes a so called transparent matrix potential [4], [3]:

\[
V^{(1)} + 4F' = 0 \quad (59)
\]

\[
F'' - V^{(1)}F - B' = 0 \quad (60)
\]

\[
B'' - V^{(1)}B = 0 \quad (61)
\]

These relations allow for further simplifications by eliminating $V^{(1)}$ and $B$ in terms of $F$ using Eq. (59) and differentiating Eq. (60) to get $B''$ which is then introduced in Eq. (61) leading to a linear algebraic equation for $B$. Inserting back the expression for the derivative of $B$ into Eq. (60) we obtain

\[
F'' + 4F'F + [(4F')^{-1}(F''' + 4F'' + 4F''')]' = 0 \quad (62)
\]

or equivalently

\[
(F'' + 4F'F)' + 4F' \int (F'' + 4F'F)dx = 0 \quad (63)
\]

a non-linear 4-th order equation for $F$ whose solution may allow to identify a class of transparent potentials in a $2 \times 2$ coupled channel problem.

A sufficient condition for $F$ to satisfy Eq. (62) is given by the simpler equation of second order

\[
(F'' + 4F'F) = \gamma F' \quad (64)
\]

with $\gamma$ an arbitrary constant number. It easy to verify the property that if $F(x)$ is a solution of the nonlinear matrix equation (64) than $\tilde{F}(x) \equiv F(x) + \alpha \cdot I$ with $\alpha = const$ is again a solution of the same equation but for the shifted value of $\tilde{\gamma} = \gamma + 4\alpha$. This peculiar property allows therefore to restrict to the case $\gamma = 0$ in (64). The solution of this equation because of (59) can be searched for, parametrizing $F(x) \equiv G(x) + iC$ with $G(x)$ and $C$ hermitean and $C$ a constant matrix. We have thus to solve

\[
G''(x) + 4G'(x)G(x) + 4iG'(x)C = 0. \quad (65)
\]

We can expand $G$ and $C$ in Pauli matrices, by a suitable rotation we can choose $c_1 = c_2 = 0$ and furthermore we assume $c_0 = 0$. Then we arrive to a system of

\[\text{Incidentally we note that Eq. (61) is a Schrödinger equation for } B \text{ with eigenvalue zero. This is related to the fact that } V^{(2)} = 0 \text{ and therefore there exists a trivial zero-energy solution, namely the constant wave function. Letting } A^+ \text{ act on this wave function one obtains the corresponding one for } h^{(1)} \text{ with the same zero energy as proportional to the matrix } B(x) \text{ acting on a constant vector.} \]
Matrix Hamiltonians...

Equations:

\begin{align*}
g'_0 + 2g^2_0 + 2\vec{g}^2 &= 2\gamma_0; \\
g'_i + 4g_0g_i - 4\epsilon_{ijk}c_3g_j &= 2\gamma_i; \quad i, j = 1, 2; \\
\epsilon_{ijk}g'_jg_k + g'_0c_3\delta_{3i} &= 0; \quad i, j, k = 1, 2, 3; \\
g_3 &= 2\gamma_3,
\end{align*}

with constant \(\gamma\)'s and obvious meaning of \(g\)'s and \(c\)'s.

A solution can be found for all \(\gamma_\mu = 0\):

\begin{align*}
g_0(x) &= \frac{1}{4x + \beta}; \\
g_1(x) &= g_0(x) \cos \phi(x); \\
g_2(x) &= g_0(x) \sin \phi(x); \\
\phi(x) &\equiv -4c_3x + \zeta,
\end{align*}

with \(\beta\) and \(\zeta\) arbitrary real constants.

By shifting \(x \to x - \beta/4\) and changing \(\zeta \to \zeta + c_3\beta\) we obtain the transparent hermitean matrix potential \(V^{(1)}(x)\) with a singularity at the origin and asymptotic long range behaviour:

\begin{align*}
V^{(1)}(x) &= \frac{1}{x^2} + \left[\frac{1}{x^2} \cos \phi(x) - \frac{4c_3}{x} \sin \phi(x)\right] \cdot \sigma_1 + \left[\frac{1}{x^2} \sin \phi(x) + \frac{4c_3}{x} \cos \phi(x)\right] \cdot \sigma_2 \\
&= \frac{1}{x^2} (1 + \hat{N}(x)) - \frac{4ic_3}{x} \sigma_3 \hat{N}(x), \quad (66)
\end{align*}

where

\[\hat{N}(x) \equiv \sigma_n \cos(4c_3x) + i\sigma_3 \sigma_n \sin(4c_3x)\]

\[\sigma_n \equiv \sigma_1 \cos \zeta + \sigma_2 \sin \zeta.\]

Due to the centrifugal singularity in this potential

\[V^{(1)}(x) \sim \frac{1}{x^2} (1 + \sigma_n) + O(1)\]

one should consider the scattering problem on the semiaxis \(x \geq 0\).

To analyze the behaviour of wave functions at the origin it is useful to choose as a basis the following matrices: \(\sigma_n, \tilde{\sigma}_n \equiv (\sigma_2 \cos \zeta - \sigma_1 \sin \zeta)\) and \(\sigma_3\) with non-standard realization: \(\sigma_n = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \tilde{\sigma}_n = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \sigma_3 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}\). Then potential \(V^{(1)}(x)\) becomes diagonal at the origin and its wave functions for \(x \to 0\) are:

\[\Psi^{(1)}(x) \sim_{x \to 0} \begin{pmatrix} a \cdot x^2 \\ b \cdot x \end{pmatrix}.\]
The dynamical symmetry operator for $h^{(1)}$ can be derived from

$$
\tilde{R}^{(1)} \equiv q^+ q^- - (h^{(1)})^2 = -4iC\partial^3 + (-4G^2 - 4C^2 - 4i[C, G] - 2G') \cdot \partial^2 - (8GG' + 8iCG' + 2G'')\partial - (2G''' + 4GG'' + 4iCG'' + 16G'^2).
$$

This operator is also singular at the origin:

$$
\tilde{R}^{(1)} \sim x \rightarrow 0 - 4ic_3\sigma_3 \partial^3 + \left(\frac{4c_3}{x} \tilde{\sigma}_n - 4c_3 + 16c_2^2\sigma_n - 32c_3x\tilde{\sigma}_n\right) \cdot \partial^2 + \frac{4ic_3}{x^2}\sigma_3 - \frac{4c_3}{x^2} \tilde{\sigma}_n - 32c_3^2\sigma_n \cdot \partial + \left(-\frac{4ic_3}{x^3}\sigma_3 + \frac{4c_3}{x^3} \tilde{\sigma}_n - \frac{12c_3^2}{x^2}\sigma_n - \frac{12c_3}{x^2} \tilde{\sigma}_n + 32c_3^2\tilde{\sigma}_n + 92c_3^4\sigma_n\right).
$$

Nevertheless it maps wave functions regular at the origin into regular ones similarly to the Example 1 (Section 3.1.).

Proceeding in the same way for $\gamma_0 > 0, \gamma_k = 0$ ($k = 1, 2, 3$) we find another solution:

$$
g_0(x) = \omega \coth(4\omega x + \beta);
$$

$$
g_1(x) = \frac{\omega \cos \phi}{\sinh(4\omega x + \beta)};
$$

$$
g_2(x) = \frac{\omega \sin \phi}{\sinh(4\omega x + \beta)};
$$

with $\phi(x)$ as before and $\omega \equiv \sqrt{\gamma_0}$. In this case the corresponding potential $V^{(1)}(x)$ has the same centrifugal behaviour at the origin. The analogous analysis of wave functions and of their transformations by symmetry operator $R^{(1)}$ can be performed.

One can check that $F(x)$ does not factorize the space dependence from a constant matrix. And also we stress that the potential $V^{(1)}(x)$ cannot be made diagonal by global rotation and therefore it is not to be viewed as a pair of standard scalar reflectionless potentials: this means that there is flux from one channel to the other.

In order to ascertain the reducible or irreducible character of the solutions of (64) it is important to clarify the conditions for reducibility for the case $V^{(2)} = 0$ and $V^{(1)}(x)$ a transparent potential. As a consequence of (69), (11), (12) these conditions read:

$$
V^{(1)} = W^2 - W' = -4F';
$$

$$
V^{(2)} = \tilde{W}^2 + \tilde{W}' + \tilde{\Delta} = 0;
$$

$$
W^2 + W' = \tilde{W}^2 - \tilde{W}' + \tilde{\Delta};
$$

$$
W + \tilde{W} = 2F;
$$

$$
B = W\tilde{W} - \tilde{W}' = 2WF + 2F'
$$

(67) \quad (68) \quad (69) \quad (70) \quad (71)
with solution
\[ \hat{\Delta} = -\xi^2; \quad \hat{W} = \xi; \quad W = 2F - \xi. \]

providing as a consequence the condition \([F, F'] = 0\), corresponding to the factor-ization of \(x\)–dependence of the matrix \(F(x)\). It is easy to check that our potentials \(V^{(1)}(x)\) do not satisfy these conditions and therefore are not reducible.

## 4. Conclusion

We have demonstrated that the SUSY approach allows to relate as SUSY partners a dynamical matrix system where the symmetry is manifest to another matrix system where this symmetry is hidden in the sense that it is not otherwise easy to guess it (see e.g. Subsection 3.1.). Therefore one is connecting systems with more complex dynamics to systems which are simpler or even solvable. For Matrix Quantum Mechanics this approach provides examples of dynamical (matrix) systems and associated symmetry operators: it is useful since a straightforward general investigation of symmetries of a dynamical systems is not an easy task. In particular the connection between degeneracy of levels and the existence of symmetry operators is not mandatory and needs further clarification which presumably will depend on detailed dynamical properties of the system under investigation.

This line of research is not academic but on the contrary should become a useful approach to investigate non-trivial quantum mechanical systems. We have restricted ourselves to 1-dim Matrix Quantum Mechanics: the algebraic methods we develop seem therefore to be specifically suited for this type of dynamical systems for which spatial symmetries (like \(O(3)\)) already have been used to reduce the problem to a one dimensional (radial) problem (separation of variables).

In absence of general theorems we have studied first and second order intertwining relations between matrix 1-dim hamiltonians discussing reducible and irreducible transformations among them. The examples we have discussed can be interpreted as coupled channel problems or Pauli-type Hamiltonians and our techniques may be instrumental to their diagonalization. We have provided for the first time explicit examples of irreducible transformations in the context of transparent matrix potentials in the framework of Matrix SUSY Quantum Mechanics.
