Predictors for difficult cecal insertion in colonoscopy: The impact of obesity indices

Soo Yun Moon, Byung Chang Kim, Dae Kyung Sohn, Kyung Su Han, Bun Kim, Chang Won Hong, Bum Joon Park, Kum Hei Ryu, Ji Hyung Nam

AIM
To identify the factors influencing cecal insertion time (CIT) and to evaluate the effect of obesity indices on CIT.

METHODS
We retrospectively reviewed the data for participants who received both colonoscopy and abdominal computed tomography (CT) from February 2008 to May 2008 as part of a comprehensive health screening program. Age, gender, obesity indices [body mass index (BMI), waist-to-hip circumference ratio (WHR), waist circumference (WC), visceral adipose tissue (VAT)]...
### INTRODUCTION

Colonoscopy is widely used for the diagnosis and treatment of colon disorders and is one of the recommended options for colorectal cancer screening[1]. Although the success rate of complete colonoscopy is reported to be as high as 95% to 99%, cecal insertion time (CIT) varies greatly in different cases and is considered a surrogate measure for difficult colonoscopy[2-4]. The mean CIT by experienced colonoscopists has been reported to be between 10 and 20 min[5]. The authors of another study insisted that experienced endoscopists should intubate the cecum in >90% of cases in <15 min[6]. Although there is no standard definition of a difficult colonoscopy, procedure times with more than 10 min for insertion or more than two attempts to reach the cecum, or finally failed insertion are often considered difficult[4,7,8].

Identifying the factors predicting longer CIT is important to colonoscopists, especially for recognition of patients who may need a longer scheduled interval, sedation and vital monitoring requirements, and better colonoscopic expertise[9]. Various factors have been implicated in influencing CIT. These factors included age, gender, quality of bowel preparation, history of prior abdominal surgery, experience of the colonoscopist, diverticulosis and constipation[4,10-14]. In addition, research on the relationship between CIT and obesity indices, such as body mass index (BMI), waist circumference (WC), visceral adipose tissue (VAT) area and subcutaneous adipose tissue (SAT) area, has been reported[9,13,15-17]. However, the results of previous studies are conflicting. A few studies on the association between VAT and CIT were reported based on the visceral fat amount using abdominal computed tomography (CT) scan[9,13]. In these previous studies, visceral fat was calculated on the basis of only one slice of abdominal CT at the umbilical level.

The aims of this study were to identify the factors influencing CIT and to evaluate the effect of obesity indices on CIT. For reflecting the effects of visceral fat on CIT more accurately, visceral fat was calculated as volume in this study.

### MATERIALS AND METHODS

#### Patients

We selected participants who received colonoscopy, abdominal CT, and questionnaire assessment from February 2008 to May 2008 among persons enrolled in our previous study on the association between abdominal VAT volume and colorectal adenoma[18]. Participants who previously had undergone surgery

...
for colorectal disease including malignancy, or had incomplete examination, inflammatory bowel disease or lack of clinical data were excluded. Surgical history and constipation were investigated through a questionnaire. Between February 2008 to May 2008, 1717 participants received colonoscopy and abdominal CT in a health screening program. Of the 1717 persons, 1678 participants met the inclusion criteria (Figure 1).

Data were collected in a prospectively maintained database that was further supplemented by a retrospective chart review. This study was approved by the institutional review board (NCC2016-0217).

**Anthropometric measurements**

BMI was calculated as body weight by height squared (kg/m²) and then divided into three categories as in previous studies: BMI < 23 kg/m², 23-24.9 kg/m², and ≥ 25 kg/m². WC was measured at the midpoint between the lower costal margin and the upper pole of the iliac crest. Patients were classified into two categories by WC according to WHO criteria: normal WC (≤ 102 cm for men, ≤ 88 cm for women) and high WC (> 102 cm for men, > 88 cm for women). Hip circumference (HC) was measured using the greatest circumference between the iliac crest and thighs. The waist-to-hip circumference ratio (WHR) was calculated as WX divided by HC. Two levels of WHR were classified as follows according to WHO criteria: normal WHR (≤ 0.9 for men, ≤ 0.8 for women) and high WHR (> 0.9 for men, > 0.8 for women).

**Measurement of abdominal adipose tissue volume**

Adipose tissue volume was calculated using 20 slices covering 100 mm from 50 mm above to 50 mm below the umbilicus as previously mentioned. VAT volume was measured as intra-abdominal fat bound by parietal peritoneum or transversalis fascia, excluding the vertebral column and paraspinal muscles. The SAT volume was calculated by subtracting the VAT volume from the total adipose tissue volume. The participants were classified into 3 groups according to VAT volume (< 500 cm³, 500-1499 cm³, and ≥ 1500 cm³) and according to SAT volume (< 1000 cm³, 1000-1999 cm³, and ≥ 2000 cm³) based on a previous study.

**Colonoscopy**

All colonoscopies were performed with an Olympus CF-Q260AL video colonoscope (Olympus Optical, Co, Ltd, Tokyo, Japan) after preparatory bowel cleansing with a 4-L of aqueous Fleet Phospho-soda (Fleet Company, Inc, Lynchburg, VA, United States). All colonoscopy procedures were performed by attending physicians specializing in endoscopy and fellows under the direction of attending physicians. Patients who chose to have sedation were given intravenous midazolam before colonoscopy initiation. The dosages were adjusted according to the patient’s age and weight. The quality of bowel preparation was graded by the colonoscopist according to the Aronchick scale and reclassified into two classes as excellent to fair and poor to inadequate for statistical analysis. The presence of diverticular disease was recorded by the colonoscopist. CIT was categorized as longer than 10 min (prolonged CIT) and shorter than or equal to 10 min.

**Statistical analysis**

Baseline characteristics of study participants and colonoscopic data were reported as the mean ± SD or number (percentage). Pearson’s χ² testing was performed for the statistical comparison of proportions among groups in univariate analysis. Only factors with P values < 0.05 in univariable analysis were subsequently estimated with odds ratios (ORs) and 95%CI using logistic regression multivariable analysis. We performed the further subgroup analysis according to the gender. A P value of less than 0.05 was considered significant. Statistical analyses were performed using the SPSS program (SPSS Inc, Chicago, IL, United States).

**RESULTS**

**Baseline characteristics**

Baseline characteristics of study participants and colonoscopic data are shown in Table 1. The mean age of 1678 participants was 50.42 ± 9.93 years and 60.3% were male. The mean BMI, WHR, WC, VAT volume, and SAT volume were 23.92 ± 2.96 kg/m², 0.90 ± 0.08, 86.95 ± 8.03 cm, 905.29 ± 475.22 cm² and 1707.72 ± 576.55 cm³, respectively. The number of participants who received abdominal surgery was 268 (16.0%). Colonoscopy was performed by an attending physician alone in 61.9% of cases and with the involvement of a fellow in 38.1% of cases. The median CIT was 7 min (range 2-56 min, IQR 5-10 min), and mean CIT was 8.58 ± 5.29 min. Four hundred (23.8%) of participants required longer than 10 min.

**Predictors of prolonged CIT**

The univariable analysis for predictors of prolonged CIT is shown in Table 2. Gender, BMI, VAT volume and
involvement of a fellow were significantly associated with a prolonged CIT. Among these variables, being female (OR = 1.29, 95% CI: 1.00-1.67, P = 0.047), BMI less than 23 kg/m² (OR = 1.62, 95% CI: 1.16-2.25, P = 0.004) or greater than or equal to 25 kg/m² (OR = 1.80, 95% CI: 1.31-2.49, P < 0.001), VAT volume smaller than 500 cm³ (OR = 1.50; 95% CI: 1.09-2.07, P = 0.013) and fellow involvement (OR = 1.73; 95% CI: 1.38-2.19, P < 0.001) were significant predictors of prolonged CIT in multivariable analysis (Table 2). When BMI and VAT volume were considered separately by multivariable analysis for gender, in men, BMI less than 23 kg/m² (OR = 1.69, 95% CI: 1.10-2.60, P = 0.017) or greater than or equal to 25 kg/m² (OR = 1.88, 95% CI: 1.28-2.75, P = 0.001) and fellow involvement were predictors of prolonged CIT. VAT volume was associated with a longer CIT in only women. In subgroup analysis by gender, lower or higher BMI and fellow involvement were predictors of a longer CIT. In women, BMI less than 23 kg/m² (OR = 1.96, 95% CI: 1.25-3.10, P = 0.004), VAT volume smaller than 500 cm³ (OR = 1.66, 95% CI: 1.17-2.35, P = 0.005) and fellow involvement were independently associated with prolonged CIT. BMI greater than or equal to 25 kg/m² (OR = 1.71, 95% CI: 0.99-2.96, P = 0.053) was marginally associated with prolonged CIT.

DISCUSSION

We found that being female, lower or higher BMI, lower VAT volume and fellow involvement were predictors of a longer CIT. In subgroup analysis by gender, lower or higher BMI and fellow involvement were predictors for prolonged CIT in both genders. However, a low VAT volume was associated with a longer CIT in only women.

In this study, female gender was identified as a predictor of longer CIT. In addition, ninety three patients of CIT more than 15 min were all women in our study. The female pelvis is deeper and more rounded than the male pelvis, which may predispose to loop formation in the sigmoid colon[16,20]. Saunders et al[20] reported total colonic length was greater in women compared to men (155 cm vs 145 cm, P = 0.005). Transverse colon length is, especially, longer in women than in men (48 cm vs 40 cm, P < 0.0001) and redundancy of the transverse colon is more frequent in women compared with that in men (62% vs 26%, P < 0.0001), which predisposes to loop formation and difficulty in passing the colonoscope in women[20]. Arcovedo et al[21] suggested that the peritoneal cavity is smaller in women, which causes a more convoluted packaging of the entire colon, which eventually forms an acute angle at the colonic flexure. A longer and more slender colonoscope could overcome those factors (longer colon length and more acute angle at the flexure) in women during colonoscopy insertion.

Table 1 Baseline characteristics of study participants (n = 1678)

| Baseline characteristics | n (%) |
|--------------------------|-------|
| Age (yr) (mean ± SD)     | 50.42 ± 9.93 |
| < 65                     | 1518 (90.5) |
| ≥ 65                     | 160 (9.5)   |
| Gender                   |         |
| Male/ Female             | 1012 (60.3)/666 (39.7) |
| Obesity indices (mean ± SD) |       |
| BMI (kg/m²)              | 23.92 ± 2.96 |
| WHR (≥ 0.74)             | 0.90 ± 0.08 |
| WC (cm) (≥ 87)           | 86.95 ± 8.03 |
| VAT volume (cm³)         | 905.29 ± 475.22 |
| SAT volume (cm³)         | 1707.72 ± 576.55 |
| History of abdominal surgery |       |
| Gynecological surgery    | 231 (13.8) |
| Gastricectomy            | 163 (9.7)  |
| Other abdominal surgery  | 5 (0.3)    |
| Constipation              |         |
| Yes/no                   | 182 (10.8)/1496 (89.2) |
| Experience               |         |
| Attending physicians/Fellow | 1039 (61.9)/639 (38.1) |
| Bowel preparation        |         |
| Excellent to fair/Poor to inadequate | 1209 (72.1)/469 (27.9) |
| Peritoneal adhesion tissue |       |
| Yes/no                   | 95 (5.7)/1583 (94.3) |
| CIT (min)                |         |
| Median CIT (range)       | 7 (2.56)/19 (5.10) |
| Mean CIT (SD)            | 8.58 ± 5.29 |
| ≤ 10 min                 | 1278 (76.2)  |
| > 10 min                 | 400 (23.8)  |

1One hundred thirty one patients were undergone multiple surgeries and duplicated with other type operation. BMI: Body mass index; WHR: Waist-to-hip circumference ratio; WC: Waist circumference; VAT: Visceral adipose tissue; SAT: Subcutaneous adipose tissue; CIT: Cecal insertion time.
BMI was reported to be one of the predicting factors of prolonged CIT, with lower BMI being associated with a difficult procedure \[17,22\]. These studies explained that this finding may be because of the relatively lower amount of visceral fat in patients with lower BMI. Visceral fat may allow for easier passage of the colonoscopy by supporting the colon in the pelvis and thus reducing loop formation \[22\]. However, another study has shown conflicting results. Jain et al \[15\] recently reported that BMI had a positive association with CIT for women, but had a negative association with CIT for men. The discrepancy in the association of BMI and CIT might be that the enrolled patients’ characteristics were different among studies. Jain et al \[15\] study excluded the patients with poor bowel preparation, a history of abdomino-pelvic surgery, and procedure done by trainees but the present study included these types of cases. In our study, when higher BMI (\(\geq 25 \text{ kg/m}^2\)) group was divided into overweight (25-29.9 \(\text{kg/m}^2\)) and obese (\(\geq 30 \text{ kg/m}^2\)) group, not obese group but overweight group was associated with prolonged CIT in multivariable analysis. Even though high BMI (\(\geq 30 \text{ kg/m}^2\)) was not significant association in univariable and multivariable analysis, there was a trend of association with prolonged CIT. The cause of these result might be the low number of high BMI (n = 45) (data not shown). BMI was used as a measure of obesity, but this may not be an accurate measure of abdominal visceral fat. BMI is an overall obesity index \[23\].

### Table 2  Cecal insertion time according to study variables, with odd ratios estimated by multivariable logistic regression analysis \(n (%)\)

| Variable                      | Cecal insertion time (min) | \(P\) value | Multivariate logistic regression analysis | \(P\) value |
|-------------------------------|---------------------------|-------------|------------------------------------------|-------------|
|                               | \(\leq 10 \ (n = 1278)\) | \(> 10 \ (n = 400)\) |                                          |             |
| Age (yr)                      |                           |             |                                          |             |
| \(< 65\)                      | 1164 (76.7)               | 354 (23.3)  |                                          | 0.125       |
| \(\geq 65\)                   | 114 (71.3)                | 46 (28.7)   |                                          |             |
| Gender                        |                           |             |                                          |             |
| Male                          | 800 (79.1)                | 212 (20.9)  | Ref                                      | 0.001       |
| Female                        | 478 (71.8)                | 188 (28.2)  | 1.29 (1.00-1.67)                         |             |
| Obesity indices               |                           |             |                                          |             |
| BMI (kg/m\(^2\))             |                           |             |                                          |             |
| \(< 23\)                      | 457 (72.2)                | 176 (27.8)  | 1.62 (1.16-2.25)                         | 0.004       |
| 23-24.9                       | 388 (83.6)                | 76 (16.4)   | Ref                                      |             |
| \(\geq 25\)                   | 433 (74.5)                | 148 (25.5)  | 1.80 (1.31-2.49)                         | < 0.001     |
| WHR (\(\geq 164\))           |                           |             |                                          |             |

\(^{a}\) \(P < 0.001\) vs BMI 23-24.9 kg/m\(^2\), \(^{b}\) \(P < 0.001\) vs BMI \(\geq 25\) kg/m\(^2\), \(^{c}\) \(P < 0.001\) vs VAT volume 500-1499 cm\(^3\). BMI: Body mass index; WHR: Waist-to-hip circumference ratio; WC: Waist circumference; VAT: Visceral adipose tissue; SAT: Subcutaneous adipose tissue.

BMI was reported to be one of the predicting factors of prolonged CIT, with lower BMI being associated with a difficult procedure \[17,22\]. These studies explained that this finding may be because of the relatively lower amount of visceral fat in patients with lower BMI. Visceral fat may allow for easier passage of the colonoscopy by supporting the colon in the pelvis and thus reducing loop formation \[22\]. However, another study has shown conflicting results. Jain et al \[15\] recently reported that BMI had a positive association with CIT for women, but had a negative association with CIT for men. The discrepancy in the association of BMI and CIT might be that the enrolled patients’ characteristics were different among studies. Jain et al \[15\] study excluded the patients with poor bowel preparation, a history of abdomino-pelvic surgery, and procedure done by trainees but the present study included these types of cases. In our study, when higher BMI (\(\geq 25 \text{ kg/m}^2\)) group was divided into overweight (25-29.9 kg/m\(^2\)) and obese (\(\geq 30 \text{ kg/m}^2\)) group, not obese group but overweight group was associated with prolonged CIT in multivariable analysis. Even though high BMI (\(\geq 30 \text{ kg/m}^2\)) was not significant association in univariable and multivariable analysis, there was a trend of association with prolonged CIT. The cause of these result might be the low number of high BMI (n = 45) (data not shown). BMI was used as a measure of obesity, but this may not be an accurate measure of abdominal visceral fat. BMI is an overall obesity index \[23\]. Men have more...
abdominal and visceral fat than women, in whom fat is distributed in more femoral and gluteal regions\(^{24}\). In our study, while in women BMI and VAT volume both showed an association with CIT, in men BMI could absorb the association between VAT volume and CIT.

In this study, lower VAT volume was a significant predictive factor of prolonged CIT in multivariable analysis in women. Visceral fat may provide a direct support for the colon in the pelvis, assisting for the easier passage of the colonoscope, preventing loop formation\(^{17-20}\).

A study demonstrated that smaller WC was associated with prolonged CIT\(^9\). In contrast, consistent with our result, Chung et al\(^{16}\) reported that there was no direct correlation between WC and CIT. It might be because WC does not seem to reflect real volume of the peritoneal cavity.

In our study, fellow involvement was significantly associated with prolonged CIT both in univariable and multivariable analysis \((P < 0.001)\). Similar results were obtained in a few previous studies\(^{13,17}\). This can be explained by the learning curve for trainees performing the colonoscopy. Park et al\(^{26}\) reported that CIT was inversely proportional to the number of colonoscopies the trainee had performed; CIT was 12 min and 8.7 min for 150 cases and 250 cases, respectively. They analyzed the factors affecting cecal intubation based on the pre- and post- colonoscopic competency of trainees. Park et al\(^{26}\) reported low BMI, inadequate

WHR: male \(n = 1009\), female \(n = 665\); WC: male \(n = 1011\), female \(n = 665\). \(P = 0.004\) vs BMI \(\geq 25\) kg/m\(^2\); \(P = 0.009\) vs BMI 23-24.9 kg/m\(^2\); \(P = 0.015\) vs VAT volume 500-1499 cm\(^3\). BMI: Body mass index; WHR: Waist-to-hip circumference ratio; WC: Waist circumference; VAT: Visceral adipose tissue; SAT: Subcutaneous adipose tissue.
bowel preparation and history of stomach surgery influenced cecal intubation during the pre-competency period and a previous history of gastric operation and inadequate bowel preparation also affected cecal intubation. The present study did not completely discriminate the status of colonoscopic competency of fellow trainees. However, our training program has rules of changing the trainee when patients suffer pain or colonoscope is sluggish at the same segment.

In subgroup analysis by experience of the colonoscopist, patient age of 65 years or over (OR = 2.08, 95%CI: 1.13-3.82, P = 0.018), BMI of 25 kg/m² or over (OR = 1.94, 95%CI: 1.21-3.12, P = 0.006), and VAT volume less than 500 cm³ (OR = 1.70, 95%CI: 1.02-2.86, P = 0.044) were associated with prolonged CIT in fellow group in multivariable analysis (Supplement Table 1). Several studies have reported different results whether older age associate with prolonged CIT. A prospective study by Zuber-gerjer et al²⁷ showed CIT was not related with age. However, consistent with our results of fellow group, a study for colonoscopy learning curves of gastroenterology fellows reported an older age was associated with a longer insertion time²⁸. Length of the entire colon has been reported to increase with age, resulting in increased redundancies and loop formation²⁹. Also, decreased elasticity of the colon associated with advanced age predisposes to loop formation during colonoscopy³⁰. These might impede the advancement of the colonoscope, especially among fellows who lack the skills. In the attending physician group, being female (OR = 1.42, 95%CI: 1.01-2.00, P = 0.043), BMI less than 23 kg/m² (OR = 1.79, 95%CI: 1.15-2.79, P = 0.010) and greater than or equal to 25 kg/m² (OR = 1.68, 95%CI: 1.07-2.64, P =0.024) were associated with prolonged CIT in multivariable analysis (Supplement Table 1).

In previous studies, poor bowel preparation prolonged CIT³¹. However, quality of bowel preparation was not associated with prolonged CIT in our study and several other studies³²,³³. This discrepancy might be due to different criteria for the bowel preparation state³⁴. In subgroup analysis by experience of the colonoscopist, poor bowel preparation was marginally associated with prolonged CIT in the fellow group but not in the attending physician group in multivariable analysis (P = 0.056, Supplement Table 1). Consistent with our study, it was reported that poor bowel preparation was a predictive factor of difficult colonoscopy in colonoscopy trainees who lacked techniques for insertion³⁵.

The advantage of this study is its large sample size including various obesity indices and prospectively collected data that was retrospectively analyzed. However, there were some limitations. First, the present study was performed by a single center. However, seven expert colonoscopists performed the endoscopy and analyzed a large number colonoscopy cases. Second, factors such as pain tolerance and use of narcotic agents, which may affect difficult colonoscopy, were not assessed. Colonoscopy provokes anxiety and discomfort in some patients. Patient stress may result in increased sympathetic outflow, an increase in bowel sensitivity with a greater need for sedative medication, and decreased procedure tolerance, resulting thereby in prolonged CIT³⁶. These factors should be evaluated in future studies.

In conclusion, Prediction of potentially difficult
patient may help the colonoscopist decide on scheduling, sedation and vital monitoring requirements, and the need for better colonoscopic expertise. Being female, lower or higher BMI than the normal range, low VAT volume and fellow involvement were predictors of longer CIT. Among obesity indices, lower or higher BMI than the normal range and low VAT volume were associated with longer CIT. Our findings suggest a role of VAT volume, not VAT area, in colonoscope insertion for the first time.

COMMENTS

Background
Colonoscopy has been the standard examination for the screening and surveillance of colorectal cancer. Cecal insertion time (CIT) varies greatly in different cases and is considered a surrogate measure for difficult colonoscopy. It is important to identify the factors predicting longer CIT. These factors included age, gender, quality of bowel preparation, history of prior abdominal surgery, experience of the colonoscopist, diverticulosis and constipation. In addition, research on the relationship between CIT and obesity indices, such as body mass index (BMI), waist circumference (WC), visceral adipose tissue (VAT) area and subcutaneous adipose tissue (SAT) area, has been reported. However, the results of previous studies are conflicting. The aim of this study was to identify the factors influencing CIT and to evaluate the effect of obesity indices on CIT.

Research frontiers
Being female, lower or higher BMI than the normal range, low VAT volume and fellow involvement were predictors of longer CIT. Among obesity indices, lower or higher BMI than the normal range and low VAT volume were associated with longer CIT.

Innovations and breakthroughs
In this study, its large sample size including various obesity indices (BMI, WHR, WC, VAT volume and SAT volume) and prospectively collected data that was retrospectively analyzed. Visceral fat was calculated as volume for precise evaluating the effects of VAT on CIT. They performed a subgroup analysis by gender.

Applications
The patients with female gender, lower or higher BMI than the normal range, low VAT volume may need a longer scheduled interval, sedation and vital monitoring requirements, and better colonoscopic expertise.

Terminology
Prolonged CIT: defined as longer than 10 min in CIT. VAT volume: measured as intra-abdominal fat bound by parietal peritoneum or transversalis fascia, excluding the vertebral column and paraspinal muscles.

Peer-review
The authors retrospectively reviewed the data of patients who underwent colonoscopy at a single Endoscopy Unit and retrieved data about various obesity indices, as well as specific data about the exams.
