ABSTRACT
Swift observed an outburst from the supergiant fast X–ray transient (SFXT) AX J1841.0–0536 on 2010 June 5, and followed it with XRT for 11 days. The X–ray light curve shows an initial flare followed by a decay and subsequent increase, as often seen in other SFXTs, and a dynamical range of \( \sim 1600 \). Our observations allow us to analyse the simultaneous broad-band (0.3–100keV) spectrum of this source, for the first time down to 0.3keV, which can be fitted well with models usually adopted to describe the emission from accreting neutron stars in high-mass X–ray binaries, and is characterized by a high absorption (\( N_H \sim 2 \times 10^{22} \text{cm}^{-2} \)), a flat power law (\( \Gamma \sim 0.2 \)), and a high energy cutoff. All of these properties resemble those of the prototype of the class, IGR J17544–2619, which underwent an outburst on 2010 March 4, whose observations we also discuss. We show how well AX J1841.0–0536 fits in the SFXT class, based on its observed properties during the 2010 outburst, its large dynamical range in X–ray luminosity, the similarity of the light curve (length and shape) to those of the other SFXTs observed by Swift, and the X–ray broad-band spectral properties.

1 INTRODUCTION

Supergiant fast X–ray transients (SFXTs) are a new class of High Mass X–ray Binaries (HMXBs) discovered by INTEGRAL (e.g. Sguera et al.2005) that are associated with OB supergiant stars via optical spectroscopy. In the X–rays they display outbursts significantly shorter than those of typical Be/X–ray binaries characterized by bright flares with peak luminosities of \( 10^{36}–10^{37} \text{erg s}^{-1} \) which last a few hours (as observed by INTEGRAL: Sguera et al.2005; Sguera et al.2006). As their quiescence is characterized by a luminosity of \( \sim 10^{32} \text{erg s}^{-1} \) (e.g. in’t Zand 2005; Bozzo et al.2010), their dynamic range is of 3–5 orders of magnitude. While in outburst, their hard X–ray spectra resemble those of HMXBs hosting accreting neutron stars, with hard power laws below 10keV combined with high energy cut-offs at \( \sim 15–30 \text{keV} \), sometimes strongly absorbed at soft energies (Walter et al.2004; Sidoli et al.2006). So, even if pulse periods have only been measured for a few SFXTs, it is tempting to assume that all SFXTs might host a neutron star. The mechanism producing the outbursts is still being debated, and it is probably related to either the properties of the wind from the supergiant companion (in’t Zand 2005; Walter & Zurita Heras 2007; Negueruela et al.2008; Sidoli et al. 2007) or to the presence of a centrifugal or magnetic barrier (Grebenev & Sunyaev2007; Bozzo et al.2008).

AX J1841.0–0536 was discovered during ASCA observations of the Scutum arm region performed on 1994 April 12, and 1999 October 3–4 as a flaring source which exhibited flux increases by a factor of 10 (up to \( \sim 10^{-10} \text{erg cm}^{-2} \text{s}^{-1} \)) with rising times on the order of 1 hr (Bamba et al.2001), a strong absorption \( N_H = 3 \times 10^{22} \text{cm}^{-2} \), and coherent pulsations with a period of 4.7394 ± 0.0008 s. A Chandra observation on 2004 May 12, which provided the coordinates refined to arcsecond accuracy \( \text{RA}(J2000) = 18^h 41^m 0.54^s, \text{Dec}(J2000) = -5^\circ 35' 46'' 8 \) (Halpern & Gotthelf 2004), found the source at a much fainter level (\( 4 \times 10^{-12} \text{erg cm}^{-2} \text{s}^{-1} \)), and with a spectrum that was fit with an absorbed power-law model \( \Gamma = 1.35 \pm 0.30, N_H = (6.1 \pm 1.0) \times 10^{22} \text{cm}^{-2} \).
A newly discovered source, IGR J18410−0535, was observed to flare by INTEGRAL on 2004 October 8 (Rodriguez et al. 2004), as it reached \( \approx 70 \) mCrab in the 20–60 keV energy range (integrated over 1700 s) and 20 mCrab in the 60–200 keV range. The source was also detected in the 20–60 keV energy range in subsequent observations, at a flux roughly half that of the initial peak, Halpern & Gotthelf (2004) identified IGR J18410−0535 as AX J1841.0−0536. Halpern et al. (2004) established that the IR counterpart was 2MASS J18410043−0535465, a reddened star with a weak double-peaked H\( \alpha \) emission line, initially classified as a Be star, which Nespoli et al. (2008) later reclassified as B1 Ib type star; this corroborated the evidence that AX J18410−0536 is a member of the SFXT class, as proposed by Negueruela et al. (2006). Sguera et al. (2009) presented the first broad-band spectrum of this source, obtained with INTEGRAL (IBIS + JEM-X), that they fit with an absorbed power-law with \( \Gamma = 2.5 \pm 0.6 \), \( N_{\text{H}} = 2.3^{+1.9}_{-1.4} \times 10^{22} \) cm\(^{-2}\).

In 2007 Swift (Gehrels et al. 2004) observed the outburst of the periodic SFXT IGR J11215−5952 (Romano et al. 2007), which allowed us to discover that the accretion phase during the bright outbursts lasts much longer than a few hours, as seen by lower-sensitivity instruments. This is contrary to what was initially thought at the time of the discovery of this new class of sources. Between 2007 October 26 and 2008 November 15, AX J1841.0−0536 was observed by Swift as part of a sample of 4 SFXTs which included IGR J116479−4514, XTE J11739−302, and IGR J17544−2619. The main aims were to characterize their long-term behavior, to determine the properties of their quiescent state, to monitor the onset of the outbursts and to measure the outburst recurrence period and duration (Sidoli et al. 2008; Romano et al. 2009a, 2010a). Approximately two observations per week were collected with the X-ray Telescope (XRT; Burrows et al. 2005) and the UV/Optical Telescope (UVOT; Roming et al. 2005). During such an intense and sensitive monitoring, AX J1841.0−0536 was the only SFXT that did not go through a bright outburst, although several on-board Burst Alert Telescope (BAT; Barthelmy et al. 2005) detections have been recorded (Romano et al. 2009a).

In this paper we report on the observations of the first outburst of AX J1841.0−0536 observed by Swift on 2010 June 5 and we compare its properties with those of the prototype of the SFXT class, IGR J17544−2619, which went into a bright outburst on 2010 March 04.

### 2 OBSERVATIONS AND DATA REDUCTION

AX J1841.0−0536 triggered the Swift/BAT on 2010 June 5 at 17:23:30 UT (trigger 423958; de Pasquale et al. 2010, Romano et al. 2010a). This is the first outburst of AX J1841.0−0536 detected by the BAT for which Swift performed a slew, thus allowing broad-band data collection. The source was detected in a 1344 s BAT image trigger, during a pre-planned observation, and there is an indication that the source was already in outburst before this observation began and well after it ended. The XRT began observing the field rather late, at 17:51:50 UT (\( T + 1708 \) s), after the very long BAT image trigger. The automated target (AT, sequences 00423958000-001) observations lasted for several orbits, until \( \sim 59 \) ks after the trigger). Follow-up target of opportunity (ToO) observations for a total of 10.8 ks were obtained (sequences 00030988093–101). The data cover the first 11 d after the beginning of the outburst.

The SFXT prototype IGR J17544−2619 triggered the BAT on 2010 March 04 at 23:13:54 UT (trigger 414875; Romano et al. 2010b). Swift executed an immediate slew, so that the narrow-field instruments (NFI) started observing it about 395 s after the trigger. The AT ran for \( \sim 5 \) ks and was followed by one ToO observation (00035056149) for \( \sim 0.8 \) ks until the source went into Moon constraint.
3 RESULTS

3.1 Light curves

Figure 1 (left) shows the Swift/XRT 0.2–10 keV light curve of AX J1841.0–0536 throughout our 2008 monitoring program (Romano et al. 2009a) background-subtracted and corrected for pile-up, PSF losses, and vignetting. All data in one observation (1–2 ks, typically) were generally grouped as one point, except for the June 5 outburst, which shows up as a vertical line on the adopted time scale [Fig. 1(right)]. The observed dynamical range of this source in the XRT band is ≈1600, considering as the lowest point a 3σ upper limit obtained on MJD 54420 at $5 \times 10^{-2}$ counts s$^{-1}$, and the highest point the peak of the June 5 outburst. Fig. 2 shows the detailed light curves during the brightest part (first orbit) of the outburst in several energy bands. The BAT light curve is rather flat and weak, but significant signal is found at the lower energies (15–50 keV).

For the timing analysis we converted the event arrival times to the Solar system barycentre with the task BARYCORR in the Chandra position (Halpern & Gotthelf 2000). We note that the XRT PC-mode readout frequency slightly undersamples the source period of $\approx 4.7$ s (Bamba et al. 2001) with respect to its Nyquist frequency, which would guarantee an unambiguous reconstruction of the signal. Timing searches were conducted in various time intervals and energy ranges around $\approx 4.7$ s, employing two methods: a fast-folding algorithm and an unbinned $Z_{\chi}^2$ test (Buccheri et al. 1983). In both cases the searches were inconclusive and we could not set meaningful upper limits on the pulsed fraction, because of the red noise and the scollaging due to the poor sampling.

3.2 Spectra

For the 2010 June 5 outburst of AX J1841.0–0536, we extracted the mean spectrum of the brightest X-ray emission (obs. 00423958000, T$^i$ + 1708 to 2390 s) and performed a fit in the 0.3–10 keV band of the data, which were rebinned with a minimum of 20 counts bin$^{-1}$ to allow $\chi^2$ fitting. An absorbed power-law model yielded a column of $N_H = 2.6^{+0.5}_{-0.4} \times 10^{22}$ cm$^{-2}$, a photon index $\Gamma = 0.9^{+0.1}_{-0.0}$, 15 degrees of freedom, dof), and a 2–10 keV unabsorbed flux of $F_{2-10\text{keV}} = 6.3 \times 10^{-10}$ erg cm$^{-2}$ s$^{-1}$. As there is no strict overlap between the BAT event data and the XRT data (see Fig. 2), we extracted one spectrum from the BAT event file of the whole observation 00423958000 (‘event’), and one from the XRT event file in the same observation. There are, however, BAT survey data available in the interval $T + 1672$–1992 s, and we extracted one (‘survey’) spectrum in this restricted interval. We performed joint fits in the 0.3–10 keV and 14–100 keV energy bands for XRT and BAT, respectively. A factor was included to allow for normalization uncertainties between the two spectra. The broad-band fits performed with the BAT ‘survey’ spectrum yield consistent results with the ones performed with the BAT ‘event’ spectrum, albeit with more unconstrained parameters due to the much more limited statistics. Therefore in Table 1 we report the fits performed with the BAT ‘event’ spectrum. A simple absorbed power-law model is clearly an inadequate representation of the X–ray emission from accreting pulsars in HMXBs, such as an absorbed power-law model with an exponential cutoff (CTOUFFPF in XSPEC) and an absorbed power-law model with a high energy cut-off (HIGHECUT). The latter models provide a significantly more satisfactory fit of the broad-band emission, resulting in a hard power-law-like spectrum below 10 keV, with a roll over of the higher energies when simultaneous XRT and BAT data fits are performed. Figure 3 shows the fits for the HIGHECUT model. Table 1 reports the average 2–10 keV luminosities. Two estimates of the distance are available, from Nespoli et al. (2008, 3.2$^{+0.7}_{-0.5}$ kpc) and Spiera et al. (2009, 6.9 ± 1.7 kpc), so we assumed 5 kpc, which is consistent with both.

3.3 IGR J17544–2619

Figure 4 shows the first orbit of the XRT and BAT light curves of the 2010 March 04 outburst of IGR J17544–2619. The XRT count rate reaches a peak exceeding 25 counts s$^{-1}$, then decreases to about 0.5 counts s$^{-1}$ and increases again up to about 20 counts s$^{-1}$ at the end of the first orbit of observations.

The XRT/WT spectrum ($T + 401$–839 s), extracted with a grade 0 selection to mitigate residual calibration uncertainties at low energies, was fit with an absorbed power law resulting in $\Gamma = 0.9^{+0.1}_{-0.0}$, $N_H = (0.9^{+0.5}_{-0.3}) \times 10^{22}$ cm$^{-2}$ ($\chi^2 = 0.989$ for 125 dof), and $F_{2-10\text{keV}} \sim 1.9 \times 10^{-9}$ erg cm$^{-2}$ s$^{-1}$ (unabsorbed). The XRT/PC spectrum ($T + 840$ to $T + 2242$ s) yields $N_H = (1.8^{+0.7}_{-0.5}) \times 10^{22}$ cm$^{-2}$, $\Gamma = 1.5^{+0.4}_{-0.3}$ ($\chi^2 = 74.8$, 17 dof) and $F_{2-10\text{keV}} \sim 1.9 \times 10^{-10}$ erg cm$^{-2}$ s$^{-1}$ (unabsorbed). We extracted a BAT spectrum strictly simultaneous with the XRT one and fitted them (0.3–10 keV, 14–50 keV) with the same models as adopted for AX J1841.0–0536. The results are in Table 1 while Figure 5 shows the fits for the HIGHECUT model. For the luminosity calculation we adopted a distance of 3.6 kpc (Kahoui et al. 2008).
Table 1. Spectral fits of XRT and BAT data of the outburst of AX J1841.0—0536 and IGR J17544—2619.

| Model | \(N_H\) (10^22 cm\(^{-2}\)) | \(\Gamma\) | \(E_c\) (keV) | \(E_l\) (keV) | \(F\) \((\text{erg cm}^{-2} \text{s}^{-1})\) | \(L\) \((\text{erg} \text{s}^{-1})\) | \(\chi^2/\text{dof}\) | \(N_H\) (10^22 cm\(^{-2}\)) | \(\Gamma\) | \(E_c\) (keV) | \(E_l\) (keV) | \(F\) \((\text{erg cm}^{-2} \text{s}^{-1})\) | \(L\) \((\text{erg} \text{s}^{-1})\) | \(\chi^2/\text{dof}\) |

4 DISCUSSION

In this paper we report our analysis of the 2010 June 5 outburst of AX J1841.0—0536 and the 2010 March 04 outburst of the SFXT prototype IGR J17544—2619. While in the first case, the image trigger was a very long one and NFI data could be collected only \(\sim 1700\) s after the trigger, when the source was relatively dim, in the second case, the slew occurred immediately after the trigger, while IGR J17544—2619 was still very bright.

Figure 5 (panels e and g) shows the full light curves of the outbursts of AX J1841.0—0536 and IGR J17544—2619 as they were observed by Swift for 11 and 2 days after the trigger, respectively.

The AX J1841.0—0536 XRT light curve shows a decreasing trend from the initial bright flare from a maximum of \(\sim 8\) counts s\(^{-1}\) down to \(\sim 0.01\) counts s\(^{-1}\) during the first day, with several flares superimposed, hence yielding a dynamic range of approximately 900 during this outburst. Then, after three days, the source count rate rose again and reached \(\sim 1\) counts s\(^{-1}\). We estimate that the observed dynamical range of this source in the XRT band, considering the historical data we collected during our monitoring campaigns (Sidoli et al. 2008, Romano et al. 2009a,b), see Fig. 1, is \(\sim 1600\), hence placing it well in the customary range for SFXTs.

The outburst of IGR J17544—2619 has similar characteristics to the one observed on 2008 March 31, as the XRT light curve shows a peak at about 25 counts s\(^{-1}\), decreases to about 0.5 counts s\(^{-1}\) and then increases again up to about 20 counts s\(^{-1}\) at the end of the first orbit (Fig. 3). This behaviour was previously observed in IGR J17544—2619 and, most notably, in IGR J08408—4503 (Romano et al. 2009a) and SAX J1818.6—1703 (Sidoli et al. 2009a), so that this multiple-peak structure of the light curve could be considered a defining characteristic of the SFXT class and it is likely due to inhomogeneities within the accretion flow (e.g. in’t Zand 2005).

Figure 5 compares the light curves of AX J1841.0—0536 and IGR J17544—2619 with the outbursts of SFXTs as observed during our monitoring campaigns with Swift. The most complete set of X-ray observations of an outburst of a SFXT is the one of the periodic SFXT IGR J11215—5952 (Romano et al. 2007, Sidoli et al. 2007, Romano et al. 2009a), which was surprisingly long. We now know that such a length of the outburst (hence the length of the accretion phase) is a common characteristic of the whole sample of SFXTs followed by Swift, and in this respect AX J1841.0—0536 fits right in, as its outburst lasted several days.

We have presented the broad-band \((0.3–100\) keV) simultaneous spectroscopy of AX J1841.0—0536. This allows us to make a comparison with the findings on the other SFXTs that were observed in the same fashion. The soft X-ray spectral properties observed during this flare are generally consistent with those observed with ASCA during the 1999 flare (Bamba et al. 2001, \(N_H = 3 \times 10^{22} \text{ cm}^{-2}\), \(\Gamma = 1\)). As AX J1841.0—0536 was observed relatively late after the trigger, no meaningful information can be derived on variability of the soft spectral parameters during the outburst, such as the absorbing column density. However, we note that the value of \(\Gamma\) in outburst follows the same trend of ‘harder when brighter’ as reported in table 4 of Romano et al. (2009a), which was based on out-of-outburst emission.

For the joint BAT+XRT spectrum during the 2010 June 5 outburst, an absorbed power-law model is an inadequate description, and more curvy models are required. We considered an absorbed power-law model with an exponential cutoff and an absorbed power-law model with a high energy cut-off, models typically used to describe the X-ray emission from accreting neutron stars in HMXBs. We obtained a good fit of the 0.3–100 keV spectrum, characterized by high absorption \(N_H \sim 2 \times 10^{22} \text{ cm}^{-2}\), a hard power law below 10 keV, and a high energy cutoff. These properties of AX J1841.0—0536 are reminiscent of those of the prototypes of the SFXT class, IGR J17544—2619 (whose data we have presented here and in Sidoli et al. 2009a, b, Romano et al. 2010a), and XTE J1739—302 (Sidoli et al. 2009a).

Although no statistically significant pulsations were found in the present data, AX J1841.0—0536 is one of the 4 SFXTs with known pulse period (Bamba et al. 2001), \(P_{\text{spin}} = 4.7394 \pm 0.0008\) s, the others being IGR J11215—5952 (186.78\pm0.3 s, Swank et al. 2007), IGR J16465—4507 (228\pm6 s, Lutovinov et al. 2005), and IGR J18483—0311 (21.0526\pm0.0005 s, Sguera et al. 2007). While lacking the detection of cyclotron lines, which would yield a direct measurement of the magnetic field \(B\) of the neutron star, an indirect estimate can be obtained by considering the high-ecut fit to the broad-band spectrum of AX J1841.0—0536 in outburst. Our value of the high energy cutoff \(E_c < 16\) keV, although loosely constrained, yields a \(B \lesssim 3 \times 10^{12}\) G (Coburn et al. 2002).

This value for \(B\), which is indeed similar to the one derived for...
the prototype of the SFXT class IGR J17544—2619, is inconsistent with a magnetar nature of AX J1841.0—0536.

In conclusion, we have shown how AX J1841.0—0536 nicely fits in the SFXT class, based on the observed properties of AX J1841.0—0536 during the 2010 June 5 outburst: a large dynamical range in X-ray luminosity, the similarity of the light curve length and shape to those of the prototype of the class IGR J17544—2619, and the X-ray broad-band spectrum, which we show here for the first time down to 0.3 keV, thus constraining both the absorption and the cutoff energy.

ACKNOWLEDGMENTS

We thank the Swift team duty scientists and science planners and the remainder of the Swift XRT and BAT teams, S. Barthelmy in particular, for their invaluable help and support.
