Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
An easy pipeline for one-step purification of SARS-CoV-2 nucleocapsid protein from insect cell suspension culture

One-step purification
SARS-CoV-2

ABSTRACT

The COVID-19 pandemic has demanded a range of biotechnological products for detection of SARS-CoV-2 variants and evaluation of human seroconversion after infection or vaccination. In this work, we describe an easy pipeline for expression of SARS-CoV-2 nucleocapsid (N) protein in insect cells followed by its purification via affinity chromatography. The N gene was cloned into the genome of Autographa californica multiple nucleopolyhedrovirus (AcMNPV) via transposition and the resulting recombinant baculovirus was used for infection of lepidopteran Sf9 cells adapted to high-density suspension. Using Tris–HCl pH 8.0 buffer as mobile phase and eluting bound proteins with 175 mM imidazole as part of a three-step gradient, an average of 1 mg N protein could be purified from each 50 mg of total protein from clarified supernatant. Such protein amount allows the manufacturing of serological tests and the development of basic studies on cellular responses to SARS-CoV-2.

Gene expression systems based on baculoviruses generate high amounts of recombinant proteins in insect cells (Chambers et al., 2018). These systems also allow the introgression of large DNA fragments and have undergone various improvements along the years that have made molecular cloning easier (Possee et al., 2019). Baculoviruses contain a circular double-stranded DNA genome and two distinct infection forms: occlusion-derived virus (ODV) and budded virus (BV) (Harrison et al., 2018). While the ODV is responsible for primary infection and virions are embedded in a protein matrix of polyhedrin, forming an occlusion body (OB), the BVs are released from host cells and are responsible for spreading viruses in insect bodies systemically.

For in vitro expression of heterologous proteins, DNA from recombinant baculovirus produced in Escherichia coli (E.coli) by site-specific transposition are transfected in insect cells and the resulting budded virions are then used for infection of new culture batches and titration (Galleno and Sick, 1999). The polyhedrin (polh) promoter, which contains transcription elements for high expression rates, often regulates the expression of recombinant genes in baculovirus-based systems (Galleno and Sick, 1999; Possee and Howard, 1987). Commonly, the gene of interest substitutes the polh gene, which is non-essential for viral replication and results in the production of virus without OB. In summary, the cloning of recombinant baculoviruses and their transfection/infection in insect cell culture batches have been simplified and are straightforward procedures for heterologous protein expression. The main bottleneck, as observed for other expression systems, is to obtain pure and stable proteins.

The current coronavirus disease 2019 (COVID-19) pandemic, caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), has demanded several biotechnological products and services for detection, treatment, and prevention of virus infection and disease. Besides the molecular tools for virus detection such as the reverse-transcriptase quantitative polymerase chain reaction (RT-qPCR), serological techniques have been highly employed to evaluate the seroconversion of infected and immunized patients (Gong et al., 2021; Machado et al., 2020). Therefore, the production of SARS-CoV-2 antigens has become indispensable for manufacturing serological tests (e.g., enzyme-linked immunosorbent assay (ELISA)) or use in basic studies, aiming a better understanding of SARS-CoV-2 infection and host-triggered immune responses. In this work, we provide a straightforward protocol for one-step purification of SARS-CoV-2 nucleocapsid (N) protein expressed in insect cells using a recombinant baculovirus.

The SARS-CoV-2 N gene was amplified by RT-PCR using purified SARS-CoV-2 RNA from a nasopharyngeal swab sample kindly supplied by the Central Laboratory of Public Health in the Federal District, Brazil. The primers N-20F (5′-GGG GAC AAG TTT GTA CAA AAA AGC AGG CTT CAT GTC TGA TAA TGG ACC CCA AAA –3′) and N-20R (5′-...

Fig. 1. Sf9 cells infected with the recombinant baculovirus vAc-N-6xHis. (A) Mock and (B) infected cells. The inset in B zooms in cells presenting hypertrophied nucleus with amorphous mass accumulation.

For recovery of infectious baculoviruses, one microgram of vAc-N-6xHis DNA was transfected into lepidopteran (Spodoptera frugiperda) Sf9 cells (10⁶) grown in a six-well plate using FuGENE® HD Transfection Reagent (Promega, Madison, Wisconsin, U.S.A.) and following the manufacturer’s protocol. Sf9 cells were maintained in TC-100 medium (Vitrocell, Campinas, São Paulo, Brazil) supplemented with 10 % fetal bovine serum, 25 μg/mL amphotericin B, and 50 mg/L gentamycin sulfate. Cells were passaged twice a week and kept at 27 °C. Seven days post-transfection, the supernatant was collected and the recombinant virus was titrated as described elsewhere (Reilly et al., 1992). Then, Sf9 cells (1.5 × 10⁵) grown in 75 cm² flasks were infected at a multiplicity of infection (M.O.I.) of 1 to increase the virus titer as described in O’Reilly et al. (O’Reilly et al., 1992). Infected Sf9 cells presented typical cytopathic effects such as increasing nucleus size, loss of attachment, and irregular shapes (Fig. 1).

For protein production, anchored Sf9 cells were adapted to grow in suspension. Cells were cultured in 50 mL supplemented TC-100 medium (in 100-mL glass flasks) under constant shaking of 100 rpm in minitron incubator shaker (INFORS HT). They were passed every 3 days, maintaining a density between 0.5 and 4 × 10⁶ cells/mL. Before infection, cells were cultured in 100 mL supplemented TC-100 medium (in 250-mL glass flasks) at density varying between 1.5–2 × 10⁶ cells/mL and then infected at M.O.I of 10. After 72 h post-infection (h.p.i.), cells were harvested by centrifugation at 2455 × g.

Pellet from each flask was resuspended with one mL lysis buffer [2.5 mL of 20 mM Tris–HCl buffer, pH 8, with 500 mM NaCl and 1 mM phenylmethylsulfonyl fluoride (PMSF) protease inhibitor] and sonicated twice for 30 s at 25 % amplitude and then centrifuged at 10,000 x g for 30 min at 4 °C. Both soluble and insoluble fractions were submitted to sodium dodecyl sulfate–polyacrylamide gel electrophoresis (SDS-PAGE) followed by western blot. Mouse monoclonal anti-6xHis and alkaline-phosphatase (ALP)-conjugated goat anti-mouse, both from Abcam (Cambridge, U.K.), were used as primary and secondary antibodies for immunoblotting, respectively. In the end, N proteins accumulated substantially more in soluble fractions (Fig. 2). Therefore, insoluble fractions were not considered for chromatography to avoid further protein refolding steps.

For SDS-PAGE, a volume of 15 μL per sample in 4X protein loading buffer (0.25 M Tris–Cl, pH 6.8, 4% SDS, 20 % glycerol, 10 % 2-mercaptoethanol, and 0.02 % bromophenol blue) was heated (100 °C) for 5 min and run through a 12 % polyacrylamide gel. Proteins were visualized by Coomassie brilliant Blue R-250 staining. For Western blotting, proteins were transferred onto Immobilon-P transfer membrane (MilliporeSigma, Burlington, Massachusetts, U.S.A.) using a Trans-Blot Semi-Dry Transfer Cell (Bio-Rad, Hercules, California, U.S.A.). Membranes were then blocked in 1X PBS buffer (137 mM NaCl, 2.7 mM KCl, 10 mM Na₂HPO₄, 2 mM KH₂PO₄, pH 7.4) containing 3% bovine serum albumin for 16 h at 4 °C. Then, they were washed three times with 1X PBS Tween (0.05 %). Primary and secondary antibodies were incubated for one hour and washed three times with 1X PBS Tween (0.05 %) between incubations. Chromogenic substrate NBT-BCIP (Promega) was used for the detection of N protein according to the manufacturer’s protocol.
Following some published technical manuals, Na for SARS-CoV-2 N protein purification by affinity chromatography.

Dialysis Tubing 10,000 MWCO (TFS), and desalted against 1X PBS for 12

HisTrap HP column (GE Healthcare) was first equilibrated with 10 ml of
buffer A (500 mM of NaCl, 20 mM Tris-HCl buffer, pH 8.0) at 4 ml/min
flow-rate. About 6 ml of clarified supernatant was loaded to the system
superloop with a syringe and flowed through the column at 1 ml/min.

Unbound proteins were washed out of the column with 25 ml buffer A at
2 ml/min flow-rate. To elute bound proteins, 65 ml buffer B (buffer A
with 500 mM imidazole) flowed through the column as a three-step
gradient of 100 mM, 175 mM, and 500 mM imidazole concentrations
at 4 ml/min. Fractions of 2 ml were collected and submitted to SDS-
PAGE and Western blot. Pure recombinant SARS-CoV-2 N protein was
obtained in fractions of bound proteins that were eluted with 175 mM
imidazole (Fig. 3 A,B). These fractions were then pooled in SnakeSkin
superloop with a syringe and flowed through the column at 1 mL/min.

About 6 mL of clarified supernatant was loaded to the system

Fig. 3. Visualization of protein fractions for and after HisTrap chromatography. (A) Protein fractions loaded for SDS-PAGE. M protein marker, 1 soluble fraction (input), 2 unbound protein fraction (wash step), 3-7 bound protein fractions (eluted with 175 mM imidazole), (B) western blot of the same fractions using mouse monoclonal anti-6xHis as primary antibody. (C) western blot of fractions 1, 2 and 3 using rabbit monoclonal anti-SARS-CoV-2 N protein as primary antibody. Secondary antibodies were conjugated with alkaline phosphatase.

All purification runs were performed on AKTA lab-scale purification
system, model AKTA Pure (GE Healthcure, Chicago, Illinois, U.S.A.).
Data were collected and analyzed using UNICORN 6.3 software. A 5 ml
HisTrap HP column (GE Healthcure) was first equilibrated with 10 ml of
buffer A (500 mM of NaCl, 20 mM Tris-HCl buffer, pH 8.0) at 4 ml/min
flow-rate. About 6 ml of clarified supernatant was loaded to the system
superloop with a syringe and flowed through the column at 1 ml/min.

Unbound proteins were washed out of the column with 25 ml buffer A at
2 ml/min flow-rate. To elute bound proteins, 65 ml buffer B (buffer A
with 500 mM imidazole) flowed through the column as a three-step
gradient of 100 mM, 175 mM, and 500 mM imidazole concentrations
at 4 ml/min. Fractions of 2 ml were collected and submitted to SDS-
PAGE and Western blot. Pure recombinant SARS-CoV-2 N protein was
obtained in fractions of bound proteins that were eluted with 175 mM
imidazole (Fig. 3 A,B). These fractions were then pooled in SnakeSkin
Dialysis Tubing 10,000 MWCO (TFS), and desalted against 1X PBS for 12 h.
Protein concentration was measured with Quant-iT™ Protein assay kit
(Invitrogen) according to the manufacturer’s protocol. An average of 1
mg N protein was purified from 50 mg of total protein in clarified supernatant. The recombinant protein was also subjected to immunoblotting with rabbit monoclonal anti-SARS-CoV-2 N protein (TFS) and ALP-conjugated goat anti-rabbit (TFS) as primary and secondary antibodies, respectively (Fig. 3C).

Several strategies were explored without success in the first attempts for SARS-CoV-2 N protein purification by affinity chromatography. Following some published technical manuals, NaPO₄ pH 7.4 buffer, for example, was used as mobile phase (buffer A), and imidazole elution was programmed to occur as a linear gradient. These methods failed to produce pure fractions containing the N protein. The mobile phase was then changed to Tris–HCl pH 8.0 buffer and imidazole elution was set up to occur as a three-step gradient as described above. Changing the mobile phase increased the binding of proteins in the column and the imidazole step-gradient resulted in fractions containing pure N protein in a higher yield (Fig. 3).

Ease of scale-up by adapting cell growth to high-density suspension and less demanding culture conditions make insect cells more advantageous than mammalian cells for expression of certain animal or animal-infecting virus proteins. Therefore, baculovirus expression systems offer more advantages than other systems for combining robust protein expression with post-translational modifications that are more comparable to mammals (Tsai et al., 2020). Baculoviruses have been used for manufacturing viral vaccines based on subunits or virus-like particles (mimicking virions) against human and veterinary pathogenic viruses (Felberbaum, 2015). During the COVID-19 pandemic, baculoviruses have been used for expression of SARS-CoV-2 spike (S) protein versions as subunits for the development of supplies, and virus-like particles and baculoviral vector-based DNA as vaccine candidates (Chen et al., 2020; Li et al., 2020; Mi et al., 2021). None of these studies included the N gene, and public protocols for heterologous expression and purification of SARS-CoV-2 N protein seem to be restricted to E. coli (Djurekic et al., 2021; Garg et al., 2020; Li et al., 2021).

Although S protein mediates SARS-CoV-2 entry in host cells and is targeted by most known neutralizing antibodies, N protein plays important roles during virus infection and host response (Dai and Gao, 2021). In charge of genome packaging, N is the most abundant protein in coronaviruses and has been shown as a major target for humoral response during SARS-CoV-2 infection, and many T cells epitopes have been mapped to it (Oliveira et al., 2020; Sartoli and Perlman, 2020; Wu et al., 2021). As a result, this protein has been widely used for quantifying IgM and IgG from COVID-19 patients (Burbelo et al., 2020; Wu et al., 2021). N protein has also key functions during SARS-CoV-2 infectivity, such as suppressing RNA interference and inhibiting interferon signaling pathways in mammalian cells (Chen et al., 2020; Li et al., 2020; Mu et al., 2020; 2020a). In summary, expression and purification of N protein are relevant for studies on SARS-CoV-2 infectivity and pathogenicity in addition to the development of diagnostic supplies. Here, we present a protocol that can be easily scaled up and reproduced in laboratories that use baculovirus-based systems for expression of recombinant proteins.
