REGULAR VARIATION OF A RANDOM LENGTH SEQUENCE OF RANDOM VARIABLES AND APPLICATION TO RISK ASSESSMENT

C. TILLIER AND O. WINTENBERGER

Abstract. When assessing risks on a finite-time horizon, the problem can often be reduced to the study of a random sequence $C(N) = (C_1, \ldots, C_N)$ of random length $N$, where $C(N)$ comes from the product of a matrix $A(N)$ of random size $N \times N$ and a random sequence $X(N)$ of random length $N$. Our aim is to build a regular variation framework for such random sequences of random length, to study their spectral properties and, subsequently, to develop risk measures. In several applications, many risk indicators can be expressed from the asymptotic behavior of $\|C(N)\|$, for some norm $\| \cdot \|$. We propose a generalization of Breiman Lemma that gives way to an asymptotic equivalent to $\|C(N)\|$ and provides risk indicators such as the ruin probability and the tail index for Shot Noise Processes on a finite-time horizon. Lastly, we apply our final result to a model used in dietary risk assessment and in non-life insurance mathematics to illustrate the applicability of our method.

1. Introduction

Risk analyses play a leading role within fields such as dietary risk, hydrology, nuclear security, finance and insurance. Moreover, risk analysis is present in the applications of various probability tools and statistical methods. We see a significant impact on the scientific literature and on public institutions (see [7], [1], [12] or [16]).

In insurance, risk theory is useful for getting information regarding the amount of aggregate claims that an insurance company is faced with. By doing so, one may implement solvency measures to avoid bankruptcy; see [22] for a survey of non-life insurance mathematics. To further illustrate the importance of risk analysis, we turn to the field of dietary risk. Here, toxicologists determine contamination levels which could later be used by mathematicians to build risk indicators. For example, in [6], authors proposed a dynamic dietary risk model, which takes into account both the elimination and the accumulation of a contaminant in the human body; see [13], [14], and [7] for a survey on dietary risk assessment.

Besides, risk theory typically deals with the occurrences of rare events which are functions of heavy-tailed random variables, for example, sums or products of regularly varying random variables; see [18] and [21] for an exhaustive survey on regular variation theory. Non-life insurance mathematics and dietary risk management both deal with a particular kind of Shot Noise Processes $\{S(t)\}_{t>0}$, defined as

$$S(t) = \sum_{n=0}^{N(t)} X_i h(t, T_i), \quad t > 0,$$

where $(X_i)_{i \geq 0}$ are independent and identically random variables, $h$ is a measurable function and $(N(t))_{t>0}$ is a renewal process; see Section 4 for details. In this context, a famous risk indicator is the ruin probability on a finite-time horizon that is the probability that the supremum of the process $S$ exceeds a threshold on a time window $[0, T]$, for a given $T > 0$. It is straightforward that maxima necessarily occur on the embedded chain and it is enough to study the discrete-time random sequence $S(N(T)) := (S(T_1), S(T_2), \ldots, S(T_{N(T)}))$, which is of random length $N(T)$. Then, instead of

Key words and phrases. Ruin theory, multivariate regular variation, risk indicators, Breiman Lemma, asymptotic properties, stochastic processes, extremes, rare events.
dealing with the extremal behavior of \( \{S(t)\}_{t \leq T} \), we only need to understand the extremal behavior of \( \|S(N(T))\|_\infty \).

We go further and point out that many risk measures in non-life insurance mathematics and in dietary risk assessment can be analyzed from the tail behavior of \( \|C(N)\| \) where \( C(N) = (C_1, \ldots, C_N) \) is a random sequence of random length \( N \) and \( \| \cdot \| \) is a norm such that

\[
\| \cdot \|_\infty \leq \| \cdot \| \leq \| \cdot \|_1.
\]

Thus we consider discrete-time processes \( C(N) = (C_1, \ldots, C_N) \) where for all \( 1 \leq i \leq N, C_i \in \mathbb{R}^+ \) and \( N \) is an integer-valued random variable \( (r.v.) \), independent of the \( C_i \)'s. We are interesting in the case when the \( C_i \)'s are regularly varying random variables. We restrict ourselves to the process \( C(N) \) which can be written in the form

\[
C(N) = A(N)X(N),
\]

where \( X(N) = (X_1, \ldots, X_N)' \) is a random vector with identically distributed marginals which are not necessarily independent and \( A(N) \) is a random matrix of random size \( N \times N \) independent of the entries \( X_i \) of the vector \( X(N) \) and of \( N \). However, \( X(N) \) and \( A(N) \) are still dependent through \( N \) that determines their dimensions. Notice that \( C(N) \) covers a wide family of processes with possibly dependent \((X_i)_{i \geq 0}\).

Our main objectives are: to define regular variation properties for a random length sequence of random variables and to study the spectral properties in order to develop risk measures. As it will become clear later, the randomness of the size \( N \) of the vector \( C(N) \) makes it difficult to use the common definition of multivariate regular variation in terms of vague convergence; see [17]. Indeed, to handle regular variation of a random sequence of random length, we need to define a regular variation framework for an infinite-dimensional space of sequences defined on \((\mathbb{R}^+)^N\). We tackle the problem using the notion of \( M \)-convergence, introduced recently in [20]. A main difference with the finite-dimensional case is that the choice of the norm matters as it determines the infinite-dimensional space to consider; see [4], [3], [25] and [26] for a comprehensive review of finite-dimensional multivariate regular variation theory.

The key point of our approach is the use of a norm satisfying [2] that allows to build regular variation via polar coordinates. This approach combined with an extension of Breiman Lemma leads to characterize the regular variation properties of \( C(N) \); see [19] for the statement and the proof of Breiman Lemma. According to the choice of the norm, it characterizes several risk indicators for a large family of processes.

For a particular class of Shot Noise Processes, we recover the result of [19] regarding the tail behavior when \( N \) is a Poisson process and when the \((X_i)_{i \geq 0}\) are asymptically independent and identically distributed. We give also the ruin probability for shot noise processes defined as [1] when the \((X_i)_{i \geq 0}\) are not necessarily independent. Moreover, we shall supplement the information missing by these two indicators by suggesting new ones; see Section 4 for details. We first turn our interest to the Expected Severity, a widely-used risk indicator in insurance. It is an alternative to Value-at-Risk that is more sensitive to the losses in the tail of the distribution. Then, we shall introduce an indicator called Integrated Expected Severity which supplies information on the total losses themselves. Lastly, our focus will shift to the Expected Time Over a Threshold, which corresponds to the average time spent by the process above a given threshold.

The paper is constructed as follows: firstly, we specify the framework and describe the assumptions on the model. In Section 3, we define regular variation for a random length sequence of random variables, followed by an extension of Breiman Lemma. Next, we attempt to apply and develop risk indicators for a particular class of stochastic processes: the Shot Noise Processes. We also apply our final result to a model used in dietary risk assessment called Kinetic Dietary Exposure Model introduced in [6]. Finally, Section 5 is devoted to proving the main results of this paper.
2. Framework and assumptions

2.1. Regular variation in \( c_{\|\|} \). In order to provide an extension of Breiman Lemma for the norm of a sequence \( C(N) = (C_1, \ldots, C_N) \) defined as in (3), we define regular variation for any vector \( X(N) = (X_1, X_2, \ldots, X_N, 0, \ldots) \) when \( N \) is a strictly positive random integer. We denote by \( c_{00} \) the set of sequences with a finite number of non-zero components. To build a regular variation framework on this space seems to be very natural for our purpose but we cannot do it since \( c_{00} \) is not complete. Indeed, it is not closed in \((l_\infty, \| \cdot \|_\infty)\). For example, consider the sequence of \( c_{00} \) with elements \( u_i = (1, 1/2, 1/3, \ldots, 1/i, 0, 0, \ldots), i \in \mathbb{N} \). Its limit as \( i \to \infty \) is not an element of \( c_{00} \). Therefore, we will choose the completion of \( c_{00} \) in \( l_\infty \) space denoted by \( c_{\|\|} \). In the rest of the paper, we write \( \| \cdot \| \) when the norm satisfies (2).

Definition 1. The space \( c_{\|\|} \) is the completion of \( c_{00} \) in \((\mathbb{R}^+)^\mathbb{N}\) equipped with the convergence in the sequential norm \( \| \cdot \| \).

For example, \( c_{\|\|,\infty} = c_0 \), the space of sequences whose limit is 0:

\[
e_0 := \left\{ u = (u_1, u_2, \ldots) \in (\mathbb{R}^+)^\mathbb{N} : \lim_{i \to +\infty} u_i = 0 \right\}.
\]

Furthermore, \( c_{\|\|} = \ell^1(\mathbb{R}^+) \), the space of sequences such that \( \sum_{i \geq 0} u_i < \infty \). In the following, we equip \( c_{\|\|} \) with the canonical distance \( d \) generated by the norm such that for any sequence \( X, Y \in c_{\|\|} \),

\[d(X, Y) = \|X - Y\| \quad \text{and we denote by} \quad \mathbf{0} = (0, 0, \ldots) \quad \text{the null element in} \quad c_{\|\|} \quad \text{.}
\]

Besides, for all \( j \geq 1 \), we denote \( e_j = (0, \ldots, 0, 1, 0, \ldots) \in c_{\|\|} \) the canonical basis of \( c_{\|\|} \) and we denote by \( S(\infty) \), the unit sphere over \( c_{\|\|} \) defined as \( S(\infty) = \{ X \in c_{\|\|} : \|X\| = 1 \} \). As \( c_{\|\|} \) is a Banach space, the notion of weak convergence holds on \( c_{\|\|} \) and one can also define regular variation as in (17).

Definition 2. A sequence \( X = (X_1, X_2, \ldots) \in c_{\|\|} \) is regularly varying if there exists a non-degenerate measure \( \mu \) such that

\[
\mu_x(\cdot) = \frac{\mathbb{P}(\text{e}^{-1}X \in \cdot)}{\mathbb{P}(\|X\| > x)} \xrightarrow{x \to \infty} \mu(\cdot),
\]

where \( \xrightarrow{\nu} \) refers to the vague convergence on the Borel \( \sigma \)-field of \( c_{\|\|} \setminus \{ \mathbf{0} \} \).

Here we want to avoid the approach using the vague convergence because it implies to find compact sets which may be complicated in several cases, especially in our infinite-dimensional framework. We use instead the "\( M \)-convergence" as introduced by [20], which instead of working with compact sets deals with special "regions" that are bounded away (BA) from the cone \( C \) we choose to remove. These BA sets will replace the "relatively compact sets" generating vague convergence.

We use the same notation as in [20], consider the unit sphere \( S(\infty) \) over \( c_{\|\|} \) and we take \( S = c_{\|\|} \). We choose to remove \( C = \{ \mathbf{0} \} \) which is a closed space in \( c_{\|\|} \) and in particular a cone. Then \( S_C = S \setminus C = c_{\|\|} \setminus \{ \mathbf{0} \} \) is an open set and still a cone. Similarly, we take \( S' = [0, \infty) \times S(\infty) \) and we remove \( C' = \{0\} \times S(\infty) \) which is closed in \([0, \infty) \times S(\infty)\) too. Moreover, for any \( X \in c_{\|\|} \), we choose the standard scaling function \( g : (\lambda, X) \rightarrow \lambda X := (\lambda X_1, \lambda X_2, \ldots), \lambda > 0, \) which is well suited for polar coordinate transformations. For \( S' \), we choose the scaling function \( (\lambda, (r, W)) \rightarrow (\lambda r, W) \) in order to make \( \{0\} \times S(\infty) \) a cone. Let \( h \) be the polar transformation such that \( h : c_{\|\|} \setminus \{ \mathbf{0} \} \rightarrow [0, \infty) \times S(\infty) \) and for all \( X \in c_{\|\|} \setminus \{ \mathbf{0} \} \),

\[
h : X \rightarrow (\|X\|, ||X||^{-1}X).
\]

As \( c_{\|\|} \) is a separable Banach space, we can apply [20] to define regular variation on this space from the \( M \)-convergence. Precisely, condition (4.2) is satisfied and Corollary 4.4 in [20] holds. Combining with Theorem 3.1 in [20] which ensures the homogeneity property of the limit measure \( \mu \) such that \( \mu(A) = \lambda^{-\alpha} \mu(A) \), for some \( \alpha > 0 \), \( \lambda > 0 \) and \( A \in c_{\|\|} \setminus \{ \mathbf{0} \} \), it leads to the following characterization of regular variation in \( c_{\|\|} \).
Proposition 3. A sequence of random elements \( X = (X_1, X_2, \ldots) \) is regularly varying if and only if the spectral measure of \( X \) is regularly varying and

\[
\mathcal{L} \left( \|X\|^{-1}X \mid \|X\| > x \right) \xrightarrow{x \to \infty} \mathcal{L}(\Theta),
\]

for some random element \( \Theta \in S(\infty) \) and \( \mathcal{L}(\Theta) = P(\Theta \in \cdot) \) is the spectral measure of \( X \).

It means that the regular variation of \( X \) is completely characterized by the tail index \( \alpha \) of \( \|X\| \) and the spectral measure of \( X \).

2.2. Assumptions. In order to get the spectral measure of any random sequence \( C(N) \) of random length \( N \) defined as in (3), we require the following conditions:

(H0) **Length:** \( N \) is a positive integer-valued r.v. such that \( E[N] > 0 \) and admits moments of order \( 2 + \alpha + \epsilon, \epsilon > 0 \).

(H0') **Poisson counting process:** \( N \) is an inhomogeneous Poisson Process with intensity function \( \lambda(\cdot) \) and cumulative intensity function \( m(\cdot) \).

(H1) **Regular variation:** The \( (X_i)_{i \geq 0} \) are identically distributed (i.i.d.) with common mean \( \gamma \) and cumulative distribution function \( c.d.f. \) \( F_X \), such that the survival function \( \overline{F}_X = 1 - F_X \) is regularly varying with index \( \alpha > 0 \), denoted by \( X \in RV_{-\alpha} \).

(H2) **Uniform asymptotic independence:** We assume a uniform bivariate upper tail independence condition: for all \( i, j \geq 1 \),

\[
\sup_{i \neq j} \left| \frac{P(X_i > x, X_j > x)}{P(X_1 > x)} \right| \xrightarrow{x \to \infty} 0.
\]

(H3) **Regularity of the norm:** The norm \( \|\cdot\| \) satisfies \( \|\cdot\|_\infty \leq \|\cdot\| \leq \|\cdot\|_1 \).

(H4) **Tail condition on the matrix \( A(N) \):** The random entries \( (a_{i,j}) \) of \( A(N) \) are independent of the \( (X_i) \). Moreover, there exists some \( \epsilon > 0 \) such that

\[
E[\|A(N)\|^{\alpha + \epsilon} N^{1 + \alpha + \epsilon}] < \infty,
\]

where \( \|\cdot\| \) also denotes the corresponding induced norm on the space of \( N \)-by-\( N \) matrices.

(H5) **The matrix \( A(N) \) is not null.**

Let us discuss the assumptions. The condition (H1) implies that the regular variation of the sequence \( C(N) = (C_1, \ldots, C_N) \) defined as in (3) comes from the regular variation of the sequence \( X(N) \) and (H2) means in addition that the probability of two components of the sequence \( X(N) \) exceeding a high threshold goes to 0. Combining (H1) and (H2), it appears that the regular variation of the sequence \( C(N) \) is mostly due to the regular variation of one of the component of \( X(N) \). Note that if the \( X_i \)'s are exchangeable and asymptotically independent, then (H2) holds. An example of a time series satisfying (H2) is a stochastic volatility model defined by

\[X_t = \sigma_t \epsilon_t, \quad t \in \mathbb{Z},\]

where the innovations \( \epsilon_t \) are standardized positive i.i.d. r.v.'s such that \( P(\epsilon_0 \neq 0) > 0 \) and \( E(\epsilon_t^{1 + \delta}) \) holds for some \( \delta > 0 \). The volatility \( \sigma_t \) satisfies the equation

\[\log(\sigma_t) = \phi \log(\sigma_{t-1}) + \xi_t, \quad t \in \mathbb{Z},\]

with \( \phi \in (0, 1) \), the innovations \( (\xi_t)_{t \in \mathbb{Z}} \) are i.i.d. r.v.'s independent of \( (\epsilon_t)_{t \in \mathbb{Z}} \) such that \( E(\zeta_0^2) < \infty \) and \( P(\zeta_t > x) \sim Kx^{-\alpha}e^{-x} \) when \( x \to \infty \) for some positive constants \( K \) and \( \alpha \neq 1 \). This is a particular case of stochastic volatility models with Gamma-Type Log-Volatility when the log-volatility is a AR(1) model. One can check that \( \sigma_t \) and \( X_t \) are regularly varying with index \( \alpha = 1 \).

Moreover, \( \log(\sigma_0), \log(\sigma_h) \) is asymptotically independent as well as \( (\sigma_0, \sigma_h) \) and \( (X_0, X_h) \) for any strictly positive \( h \); see (4) for details.

Besides, (H3) implies \( \ell^1(\mathbb{R}^+) \subseteq c_0 \subseteq c_0 \) and holds for any \( \ell^p \) norm for \( 1 \leq p \leq \infty \). This condition is always assumed in the paper, even if many conditions could be weakened if we only considered the norm \( \|\cdot\|_\infty \).

But our aim is to develop a method which can be applied for a broad class of processes.
and norms. Finally, (H4) requires more finite moments on \( N \) than (H0). This condition can be viewed as an extension of the moment condition of the Breiman’s lemma. It is required to estimate the tail of \( \|C(N)\| = \|A(N)X(N)\| \) from the one of \( \|X(N)\| \) and it is not restrictive in practice when \( N \) satisfies (H0’).

**Lemma 4.** Assume that (H3) holds and that \( A(N) = (a_{i,j})_{1 \leq i,j \leq N} \) has i.d components satisfying \( \mathbb{E}[|a_{1,1}|^p] < \infty \) for some \( p > \alpha \vee 1 \). If \( \mathbb{E}[N^{2p+1}] < \infty \) then (H4) holds.

**Proof.** From (H3) and convexity, we have

\[
\mathbb{E} \left[ \|A(N)\|^p N^{p+1} \right] \leq \sum_{n=1}^{\infty} \mathbb{E} \left[ \|A(N)\|^p N^{p+1} 1_{N=n} \right]
\]

\[
\leq \sum_{n=1}^{\infty} \mathbb{E} \left[ \left( \sup_{1 \leq j \leq n} \sum_{i=1}^{n} |a_{i,j}| \right)^p n^{p+1} \mathbb{P}(N = n) \right]
\]

\[
\leq \sum_{n=1}^{\infty} n \mathbb{E} \left[ \left( \sum_{i=1}^{n} |a_{i,1}| \right)^p \right] n^{p+1} \mathbb{P}(N = n)
\]

\[
\leq \sum_{n=1}^{\infty} n^{p-1} \mathbb{E}[|a_{1,1}|^p] n^{p+2} \mathbb{P}(N = n)
\]

\[
\leq \mathbb{E}[|a_{1,1}|^p] \sum_{n=1}^{\infty} n^{2p+1} \mathbb{P}(N = n) < \infty
\]

and then (H4) holds. \( \square \)

3. Regular variation of random sequences of random length

3.1. Regular variation properties in \( c_{\|\cdot\|} \) under (H0). We focus in providing regular variation properties for a sequence \( X(N) = (X_1, X_2, \ldots, X_N, 0, \ldots) \) under (H0), written \( X(N) = (X_1, X_2, \ldots, X_N) \) for short in the sequel. We write \( \mathbf{0} \) the null element in \( c_{\|\cdot\|} \). The sequence \( X(N) \) can be seen as an element of \( c_{\|\cdot\|} \) whose the number of non-null elements is driven by the random variable \( N \).

**Proposition 5.** A sequence of random elements \( X(N) = (X_1, X_2, \ldots, X_N) \in c_{\|\cdot\|} \setminus \{\mathbf{0}\} \) for \( N \) satisfying (H0) is regularly varying if the random variable \( \|X(N)\| \) is regularly varying and

\[
\mathcal{L} \left( (\|X(N)\|^{-1} X(N) \mid \|X(N)\| > x) \right) \xrightarrow{x \to \infty} \mathcal{L}(\Theta(N)),
\]

for some random element \( \Theta(N) \in S(\infty) \). The distribution of \( \Theta(N) \) is the spectral measure of \( X(N) \).

**Proof.** The random variable \( N \) is necessarily not null thanks to (H0). Then the proof is straightforward from Proposition 9. \( \square \)

Notice that \( \Theta(N) \in S(\infty) \) is an infinite sequence \( \Theta(N) = (\Theta_1(N), \Theta_2(N), \ldots) \). The following proposition is relevant for the results of this paper. It is a first example of such regularly random vectors of random length under (H3). Besides, it is an extension of Lemma A6 in [30].

**Proposition 6.** Let \( X(N) = (X_1, \ldots, X_N) \in c_{\|\cdot\|} \) such that (H0)-(H3) hold. Then we have

\[
\lim_{x \to \infty} \frac{\mathbb{P}(\|X(N)\| > x)}{\mathbb{P}(X_1 > x)} = \mathbb{E}[N] > 0.
\]

**Proof.** See Section 5. \( \square \)
Here the moment condition in (H0) is required to handle the \( \| \cdot \|_1 \) case. Releasing the assumption (H0), it is easy to draw an i.i.d. sequence of random length which is regularly varying in \( c_{\| \cdot \|} \) but not in \( c_{\| \cdot \|_\infty} \). For instance, for the \( \| \cdot \|_\infty \) case, the result is true under the integrability of \( N \) only but this assumption is not sufficient to ensure the convergence for the \( \| \cdot \|_1 \) case. Note also that (H3) is required since the convergence might not hold for some norms that do not satisfy (H3). From this proposition, a characterization of the spectral measure of \( X(N) \) is possible.

**Proposition 7.** If (H0)-(H3) hold then \( X(N) = (X_1, \ldots, X_N) \in c_{\| \cdot \|} \setminus \{0\} \) is regularly varying in the sense of Proposition 6 and its spectral measure is characterized by

\[
P(\Theta(N) = e_j) = \frac{P(N \geq j)}{E[N]}, \quad j \geq 1.
\]

**Proof.** See Section 5.

The spectral measure \( \Theta(N) \) of \( X(N) \) belongs to \( S(\infty) \), the unit sphere on the infinite-dimensional space \( c_{\| \cdot \|} \). We cannot draw straightforwardly the parallel between regular variation in \( \mathbb{R}^n \) and in \( c_{\| \cdot \|} \) and \( \Theta(N) \) needs to be handle carefully. We have not achieved to find a way to define properly the distribution of \( \Theta(N) \) given that \( N = n \). Following arguments in [20] to handle regular variation of the infinite-dimensional space \( \mathbb{R}^\infty \) from regular variation of the finite-dimensional space \( \mathbb{R}^p \), \( p > 0 \), the natural choice would have been to consider the projection operator \( \text{Proj}_n : c_{\| \cdot \|} \to \mathbb{R}^n \) defined as 

\[
\text{Proj}_n(X) = (X_1, X_2, \ldots, X_n) = (X_1, X_2, \ldots, X_n)
\]

and to define the distribution of \( \Theta(N) \) given \( N = n \) as \( \mathcal{L}(\Theta(N)|N = n) = \mathcal{L}(\text{Proj}_n(\Theta(N))) \). Then, for all \( j \leq n \), we would have had

\[
P(\Theta(N) = e_j|N = n) = \frac{\sum_{j=1}^{n} P(\Theta(N) = e_j)}{\sum_{j=1}^{n} P(N \geq j)} = \frac{P(N \geq j)}{\sum_{j=1}^{n} P(N \geq j)},
\]

which is not coherent with the distribution of \( \Theta(N) \) provided in Proposition 6 and this representation does not work. This provides further evidence that \( \Theta(N) \) cannot admit the representation \( (\Theta_1(N), \ldots, \Theta_N(N)) \) and must be considered as an infinite-dimensional random element. Nonetheless, note that \( \sum_{j=1}^{\infty} P(\Theta(N) = e_j) = 1 \) and then \( \Theta(N) = \bigcup_{j=1}^{\infty} e_j \) almost surely, thus we fully characterized the spectral measure of \( X(N) \) in Proposition 7.

**Remark 8.** When \( N = n \) for a fixed \( n \geq 1 \), it follows that for all \( 1 \leq j \leq n \), \( P(\Theta(n) = e_j) = n^{-1} \).

3.2. Generalization to the matrix product. We generalize this approach to sequences in \( c_{\| \cdot \|} \) defined from the product of \( X(N) \) by a random matrix \( A(N) = (a_{ij})_{1 \leq i \leq j \leq N} \) of random size \( N \times N \). We denote this vector \( C(N) = A(N)X(N) \), which is of length \( n \). We keep the previous notation and we denote by \( A_k(N) \) the \( k \)-th column of the matrix \( A(N) \). Here and in what follows, we work under the assumptions (H3) and (H4). Notice that (H3) implies that the canonical basis of \( c_{\| \cdot \|} \) denoted by \( (e_i)_{i \geq 1} \) is standardized, i.e. for all \( i \geq 1 \), \( \|e_i\| = 1 \).

Note that on \( N = n \), \( A(n) \) and \( X(n) \) are independent. Then we directly deduce from Remark 8 and the multivariate Breiman’s lemma (see Proposition 5.1 in [4]) the following useful proposition.

**Proposition 9.** Let \( A(N) \) and \( X(N) \) be defined as above and assume (H0)-(H3). Then, for any \( n \geq 1 \), we have

\[
P(\|x^{-1}C(n)\| > x)/P(X_1 > x) \xrightarrow{x \to \infty} E \left[ \sum_{k=1}^{n} \|A_k(n)\|^\alpha \right].
\]

Moreover \( C(n) \) is regularly varying under (H5).

**Proof.** From Proposition 5.1 in [4], we have

\[
P(x^{-1}A(n)X(n) \in \cdot)/P(\|X(n)\| > x) \xrightarrow{x \to \infty} E[\mu \circ A(n)^{-1}(\cdot)]
\]
with $\mu$ a radon measure defined by
\[ P(x^{-1}X(n) \in \cdot)/P(\|X(n)\| > x) \xrightarrow{x \to \infty} \mu(\cdot). \]

Then,
\[ P(\|x^{-1}A(n)X(n)\| \in \cdot)/P(\|X(n)\| > x) \xrightarrow{x \to \infty} \mathbb{E}[\mu \circ A(n)^{-1}(\cdot)]. \]

By homogeneity of $\mu$, it follows that
\[ P(\|A(n)X(n)\| > x)/P(\|X(n)\| > x) \xrightarrow{x \to \infty} \mathbb{E}[\mu(\{x : \|A(n)x\| > 1\})] = \mathbb{E}[\|A(n)\Theta(n)\|^\alpha]. \]

From Remark \[8\] $\Theta(n) = \bigcup_{i \leq n} e_i$ and $P(\Theta(n) = e_i) = n^{-1}$ for all $i \leq n$ which leads to
\[ \mathbb{E}[\|A(n)\Theta(n)\|^\alpha] = n^{-1} \mathbb{E}\left[ \sum_{k=1}^n \|A_k(n)\|^\alpha \right], \]

Then, from Lemma \[27\] we have
\[ P(\|A(n)X(n)\| > x)/P(X_1 > x) \xrightarrow{x \to \infty} \mathbb{E}\sum_{k=1}^n \|A_k(n)\|^\alpha, \]

which concludes the proof. \[\square\]

This proposition plays a leading role in the proof of the following theorems, which generalize the Breiman’s lemma to random length sequences of r.v.’s asymptotically independent and identically distributed.

**Theorem 10.** Let (H0)-(H4) hold and $C(N) = A(N)X(N)$, then we have
\[ \lim_{x \to \infty} \frac{P(\|C(N)\| > x)}{P(X_1 > x)} = \mathbb{E}\left[ \sum_{k=1}^N \|A_k(n)\|^\alpha \right]. \]

The proof is postponed to Section 5. Notice that Theorem \[10\] holds if $A(N)$ does not necessarily satisfy (H5) and then we allow that $P(\|C(N)\| > x)/P(X_1 > x) \to 0$ when $x$ goes to infinity; see Section 5 for details. Under the additional assumption (H5), we are now ready to prove that $C(N)$ is regularly varying.

**Theorem 11.** If (H0)-(H5) hold, $C(N) = A(N)X(N)$ is regularly varying and its spectral measure is given by
\[ P(\|C(N)\|^{-1}C(N) \in \cdot \mid \|C(N)\| > x) \xrightarrow{x \to \infty} \frac{\mathbb{E}\sum_{k=1}^N \|A_k(n)\|^\alpha \mathbb{I}_{\{k \leq N\}}}{\mathbb{E}\sum_{k=1}^N \|A_k(n)\|^\alpha}. \]

The proof is postponed to Section 5. Although the characterization is common for any norm such that (H3) holds, the result essentially depends on the choice of the norm. Despite this remark, it is noteworthy that the spectral measure can be described in a unified way even if it belongs to different spaces, regarding the choice of the norm.

In the sequel, we assume that (H0)-(H5) hold. Following \[4\], for all $i \leq N$, we have
\[ \lim_{x \to \infty} \lim_{\epsilon \to 0} P(\|C_i(N)\| > x \epsilon \mid \|C(N)\| > x) = \mathbb{E}[\Theta_i(N)^\alpha]. \]

From Theorem \[11\] we have
\[ \mathbb{E}[\Theta_i^\alpha] = \frac{\mathbb{E}\left[ \sum_{k} |A_k(n)|^\alpha \mathbb{I}_{\{k \leq N\}} \right]}{\mathbb{E}\left[ \sum_k |A_k(n)|^\alpha \right]} \cdot \frac{\mathbb{E}\left[ \sum_{k} |a_{i,k}|^\alpha \mathbb{I}_{\{i \leq N\}} \right]}{\mathbb{E}\left[ \sum_{k} |A_k(n)|^\alpha \right]} = \frac{\mathbb{E}\left[ \sum_{k} |a_{i,k}|^\alpha \mathbb{I}_{\{i \leq N\}} \right]}{\mathbb{E}\left[ \sum_{k} |A_k(n)|^\alpha \right]}.
Let us consider the asymptotically independent case when \( a_{k,i} = \mathbb{I}_{\{i=k\}} \) then,

\[
\mathbb{E}[|\Theta_1(N)|^\alpha] = \frac{\mathbb{E}\left[\sum_{k=1}^{N} \mathbb{I}_{\{i=k\}}\right]}{\mathbb{E}[N]} = \frac{\mathbb{P}(N \geq i)}{\mathbb{E}(N)}.
\]

It is a mean constraint on the spectral measure. To be precise, if the margins of the random vector are identically distributed, then necessarily \( \mathbb{E}[|\Theta_1(N)|^\alpha] = \mathbb{P}(N \geq i)/\mathbb{E}(N), i \geq 1. \) We recover the mean constraint \( \mathbb{E}[|\Theta_1(n)|^\alpha] = n^{-1}, 1 \leq i \leq n \) when \( n \) is fixed; see [15].

4. Applications

This section is devoted to calculating the constant \( \sum_{k=1}^{N} \|A_k(N)\|^\alpha \) for various examples. To obtain explicit results, we assume in this part that \( N \) is defined as in (H0') which implies in particular that the moment condition (H4) holds. The result is derived thanks to the order statistics property of a Poisson process (see [22], Section 2.1.6). The computation of the constant \( \sum_{k=1}^{N} \|A_k(N)\|^\alpha \) for different norms and different matrices \( A(N) \) permits to develop various risk measures.

As mentioned before, \( C(N) \) covers a wide family of processes. We deal here with an example of a Shot Noise Process (SNP). SNP were first introduced in the 20’s to study the fluctuations of current in vacuum tubes and used in an insurance context from the second half of the twentieth century; see [30] and [28] for more details on the SNP theory. We restrict ourselves to the study of particular SNP’s defined by

\[
Y(t) = \sum_{i=1}^{N(t)} X_i \times h_i(t, T_i), \quad \forall \ t \geq 0,
\]

where \((h_i)_{i \geq 0}\) are i.i.d. non-negative measurable random functions called "shock functions", which are independent of the shocks \((X_i)_{i \geq 0}\). The "shock instants" \((T_i)_{i \geq 0}\) are r.v.’s independent of \((X_i)_{i \geq 0}\) such that for all \( i \geq 0, T_i = \sum_{0 \leq k \leq i} \Delta T_k \), where \((\Delta T_k)_{k \geq 0}\) is an i.i.d. sequence of r.v.’s called "inter-arrivals". Under (H0'), the inter-arrivals are exponentially distributed. In this context, \( N(t) = \{\# i : T_i \leq t\} \) is a renewal process which counts the number of claims that occurred until time \( t \); see [22] for a survey on renewal theory. We assume that for all \( i \geq 0, t > 0 \) and \( \alpha > 0 \), there exists \( \epsilon > 0 \) such that \( \mathbb{E}[h_i^{\alpha+\epsilon}(t, T_i)] < \infty \).

In the sequel, we denote by \( F_X^+ \) the integrated tail distribution associated to the r.v. \( X \), which is defined for all \( y > 0 \) by

\[
F_X^+(y) = \frac{1}{\gamma} \int_y^{+\infty} \mathbb{P}_X(x)dx,
\]

with \( \gamma = \mathbb{E}(X) \). We write \( N(t) \) instead of \( N \) to stress the fact we are dealing with counting processes and therefore we study the process through time.

4.1. Asymptotic tail behavior of SNP’s. We first apply our method to determine the asymptotic behavior of a SNP defined as [4] as a corollary of our main result.

**Corollary 12.** Under (H0')-(H1)-(H2), assume that the random functions \( h_j(T, \cdot) \)’s are i.i.d., independent of the \( T_j \)’s and integrable of order \( p > \alpha \), then

\[
\lim_{x \to \infty} \frac{\mathbb{P}(Y(T) > x)}{\mathbb{P}(X_1 > x)} = m(T) \mathbb{E}[h_0^\alpha(T, V_0)],
\]

where \( V_0 \) admits the density \( \lambda(t)/m(T), 0 \leq t \leq T \).

This corollary plays a leading role to determine the risk indicators in Section 4.3. Besides, we recover the recent results of [30] and [19] on the tail of \( \{Y(T)\}_{T \geq 0} \).
Assume that the conditions of Corollary 12 hold. If Corollary 13 holds and we check that (H4) holds and we apply Theorem 10 in order to obtain
\[
\lim_{x \to \infty} \frac{P(Y(T) > x)}{P(X_1 > x)} = \mathbb{E} \left[ \sum_{k=1}^{N(T)} \|A_k(N(T))\|^\alpha \right].
\]

Note that for all \(k \leq N(T)\), \(\|A_k(N(T))\|^\alpha = h_k^\alpha(T,T_k).\) Let \(V_{(k)}^j\) be the \(k\)-th order statistic associated to the \(i.i.d.\) sequence \((V_0, V_1, \ldots)\) distributed as \(V_0\). From [22], Section 2.1.6, \((T_k \mid N(T)) \overset{d}{=} V_{(k)}^j\) and it follows that
\[
\mathbb{E} \left[ \sum_{k=1}^{N(T)} h_k^\alpha(T,T_k) \right] = \mathbb{E} \left[ \sum_{k=1}^{N(T)} h_k^\alpha(T,T_k) \mid N(T) \right] = \mathbb{E} \left[ \sum_{k=1}^{N(T)} h_k^\alpha(T,V_{(k)}^j) \mid N(T) \right] = \mathbb{E} \mathbb{E}[N(T)\mid\mathbb{E}[h_0^\alpha(T,V_0)],
\]

which is the desired result. \(\square\)

Notice that the asymptotic behavior of \(Y(T)\) as \(T \to \infty\) relies on the one of the shock function \(h_0\). One case corresponds to \(\mathbb{E}[N(T)\mid\mathbb{E}[h_0^\alpha(T,V_0)] \to C\) for some constant, then \(Y(\infty)\) may be well defined. Thus, the SNP may admit a stationary distribution \(Y(\infty) = \sum_{i \geq 1} X_i \times h_i(T,T_i)\) that is regularly varying similarly than \(X_1\). Another case corresponds to \(\mathbb{E}[N(T)\mid\mathbb{E}[h_0^\alpha(T,V_0)] \to \infty\) and then it is very likely that \(Y(\infty) = \infty\) a.s.. In the latter case, we have explosive shot noise processes.

4.2. Ruin probability. We are interesting in determining the finite-time ruin probability \(\psi\) of a SNP defined as in [4], which is the probability that \(Y(t)\) exceeds some given threshold \(x \in \mathbb{R}^+\) on a period \([0, T]\), \(i.e.\)
\[
\psi(x, T) = \mathbb{P}\left( \sup_{0 \leq t \leq T} Y(t) > x \right), \quad T > 0.
\]

Corollary 13. Assume that the conditions of Corollary 12 hold. If \(h_j(\cdot, T)\) is a non-increasing function for any \(T > 0\), then,
\[
\lim_{x \to \infty} \frac{\psi(x, T)}{P(X_1 > x)} = m(T)\mathbb{E}[h_0^\alpha(V_0,V_0)].
\]

Notice that if \(h_j(\cdot, T)\) is a non-decreasing function for any \(T > 0\), then the maximum of the SNP is achieved at time \(T\) and so the ruin probability can be computed thanks to Corollary 12. An intermediate example is when the random shock function \(h_0\) can be either increasing and decreasing; see Section 4.3.

Proof of Corollary 13. Let \(T\) be a strictly positive constant. Note that in this setup, the maximum of the process \(\{Y(T)\}_{T \geq 0}\) is necessarily reached on its embedded chain \(\{Y(T_k)\}_{k \geq 0}\). Then, it is equivalent to the study the tail of \(\max_{1 \leq k \leq N(T)} \sum_{j=1}^k X_j h_j(T_k,T_j)\). To do so, let \(C(N(T)) = A(N(T))X(N(T))\) with \(A(N(T))\), the lower triangular matrix such that \(a_{k,j} = h_j(T_k,T_j)\) for \(1 \leq j \leq k\) and \(a_{k,j} = 0\) for
\[ k + 1 \leq j \leq N. \] Now, observe that \[ \max_{1 \leq k \leq N(T)} \sum_{j=1}^{k} X_j h_j(T_k, T_j) = \|C(N(T))\|_\infty. \] We check that (H4) holds thanks to Lemma 3 and from Theorem 11, we have

\[
\lim_{x \to \infty} \frac{\|C(N(T))\|_\infty}{P(X_1 > x)} = \mathbb{E} \left[ \sum_{k=1}^{N(T)} \|A_k(N(T))\|_\infty \right].
\]

Conditionally on \( N(T) \), we have \( A_j(N(T)) = (0, \ldots, 0, h_j(V_{(j)}, V_{(j)}), \ldots, h_j(V_{(N(T))}, V_{(j)}))' \). Then, \( \|A_j(N(T))\|_\infty = h_j^0(V_{(j)}, V_{(j)}) \) and with similar arguments than in the previous corollary, it follows that

\[
\mathbb{E} \left[ \sum_{k=1}^{N(T)} \|A_k(N)\|_\infty \right] = \mathbb{E} [N(T) \times \mathbb{E} [h_0^0(V_0, V_0)]]
\]

which concludes the proof. \( \square \)

**Remark 14.** If for \( T > 0, h_0(T, T) = c \) with \( c > 0 \), then Corollary 13 extends to any counting process \( N \) providing \( \psi(x, T) \sim e^c \mathbb{E}[N(T)]P(X_1 > x) \) as \( x \to \infty \). Besides, in such case where \( h_0(T, T) \) is constant, a sandwich argument yields also the desired result. Indeed, we have

\[
P \left( c \max_{i=1, \ldots, N(T)} X_i > x \right) \leq P \left( \max_{i=1, \ldots, N(T)} \left\{ \sum_{k=1}^{i} X_i h_i(T, T_i) \right\} > x \right) \leq P \left( c \sum_{i=1}^{N(T)} X_i > x \right).
\]

So Proposition 6 can be directly used to find again that

\[
\psi(x, T) \sim e^c \mathbb{E}[N(T)]P(X_1 > x).
\]

**Remark 15.** We obtain an asymptotic relation between the tail behavior and the ruin probability of a process defined as in 44. Precisely, we have

\[
P(Y(T) > x) \sim \frac{\mathbb{E}[h_0^0(T, V_0)]}{\mathbb{E}[h_0^0(V_0, V_0)]} \psi(x, T)
\]

when \( h_j(\cdot, T) \) is a non-increasing function for any \( T \) and

\[
P(Y(T) > x) \sim \psi(x, T)
\]

when \( h_j(\cdot, T) \) is a non-decreasing function.

### 4.3. Other risk indicators

We propose in this part three indicators to supplement the information given by the ruin probability and the tail behavior. The ruin probability permits to know if the process has exceeded the threshold but provides no information about the exceedences themselves or about the duration of the exceedences.

To fill the gap, we first bear our interest on the Expected Severity. Then, we present an indicator called Integrated Expected Severity, which provides information on the total of the exceedences. Finally, we are interested in the Expected Time Over a Threshold which corresponds to the average time spent by the process over a threshold. We keep the previous notation and features on the process defined as 44.

#### 4.3.1. The Expected Severity and the Integrated Expected Severity

Let us first begin with the Expected Severity. By definition, the Expected Severity for a given threshold \( x \), written \( ES(x) \), is the quantity dealing with the mean of the excesses knowing that the process has already reached the reference threshold \( x \), defined for all \( T > 0 \) by \( \mathbb{E}[(Y(T) - x)_+] \), where \( [\cdot]_+ \) is the positive part function.

**Proposition 16.** Assume that the conditions of Corollary 13 hold. For any \( T > 0 \), the expected severity of a process defined as 44 is given by

\[
ES(x) \sim \gamma m(T)\mathbb{E}[h_0^0(T, V_0)] \frac{F_X'(x)}{x}.
\]
Proof. By definition,
\[
E[Y(T) - x] = E\left[\sum_{i=1}^{N(T)} X_i h_i(T, T_i) - x\right] = \int_x^{+\infty} P\left(\sum_{i=1}^{N(T)} X_i h_i(T, T_i) > y\right) dy.
\]
From Corollary 12 it follows that
\[
ES(x) \sim \int_x^{+\infty} E[N(T)] E[h_0^0(T, V_0)] P(X > y) dy
\]
and the desired result follows.

Proposition 17. Assume that the conditions of Corollary 12 hold. The Integrated Expected Severity for a process defined as (4) for large values of \( x \) is given by
\[
IES(x) \sim \int_0^T E[Y(t) - x] dt.
\]
Proof. By definition,
\[
IES(x) = \int_0^T E[Y(t) - x] dt.
\]
From the previous Proposition, we directly obtain the result.

4.3.2. The Expected Time Over a Threshold. The Expected Time Over a reference threshold \( x \), written \( ETOT(x) \), provides information about how long does the process stay, in average, above a threshold \( x \), knowing that it has already reached it. It is defined for all \( x > 0 \) by
\[
ETOT(x) = E\left[\int_0^T 1_{\{Y(t) \in [x, \infty]\}} dt \mid \max_{0 \leq t \leq T} Y(t) > x\right].
\]

Proposition 18. Assume that the conditions of Corollary 12 hold. For large values of \( x \), the \( ETOT(x) \) for the process defined as (4) is given by
\[
ETOT(x) \sim \frac{\int_0^T m(t) E[h_0^0(t, V_0)] dt}{m(T) E[h_0^0(V_0, V_0)]}.
\]
Proof. By definition,
\[
ETOT(x) = \frac{E\left[\int_0^T 1_{\{Y(t) \in [x, \infty]\}} dt\right]}{\psi(x, T)}.
\]
Let \( A(N(t)) \) be the diagonal matrix such that for all \( 1 \leq j \leq N(t), a_{jj} = h_j(t, T_j). \) Note that
\[
\int_0^T E[1_{\{Y(t) > x\}}] dt = \int_0^T P(Y(t) > x) dt = \int_0^T P(\|C(N(t))\|_1 > x) dt.
\]
Plug-in Corollary 12 in the previous expression concludes the proof.
Remark 19 (The extremal index for shot noise processes). Under the previous assumptions, we define the extremal index \( \theta \in [0, \infty] \) as the inverse of \( \lim_{T \to \infty} \lim_{x \to \infty} \frac{\int_0^T m(t)E[h_0^\alpha(t, V_0)]dt}{m(T)E[h_0^\alpha(V_0, V_0)]} \to \frac{1}{\theta} \).

It can be seen as a continuous version of the extremal index for discrete time-series; see [27]. To be precise, it measures the clustering tendency of high threshold exceedences and how the extreme values cluster together. In this context, \( \theta \) does not still belong to \([0, 1]\) but to \([0, \infty]\). Notwithstanding, the inverse of the extremal index \( \theta^{-1} \) indicates somehow, how long (in mean) an extremal event will occur, due to the dependency structure of the data. For instance \( \theta = 0 \) for a random walk such that \( h_i = 1 \) and extremal events may long forever. At the opposite, in the asymptotic independent case \( h_i(t, v) = 1_{\{t=v\}} \), then \( \theta = +\infty \) and extremal events occur instantaneous only.

4.4. Application in dietary risk assessment and in non-life insurance mathematics. The shot noise process defined as in [4] intervenes in many applications in which sudden jumps occur such as in insurance to model the amount of aggregate claims that an insurer has to cope with; see [2] and [12] and [22].

In dietary risk assessment and non-life insurance, we typically consider deterministic shock functions defined for all \( 0 \leq x \leq t \) by \( h(t, x) = e^{-\omega(t-x)} \), with a shape parameter \( \omega > 0 \); see [6], [7] and [22] for more details. We call this model Exp-SNP for Exponential Shot Noise Process.

In [6], authors suggested a model, called Kinetic Dietary Exposure Model (KDEM), to represent the evolution of a contaminant in the human body. Their model is a discrete-time risk process which can be expressed from a Exp-SNP on the shock instants; see Remark 21. In this context, shocks are regularly varying distributed intakes which arise according to \( N(T) \) and \( \omega \) is an elimination parameter.

We consider below an extension of the KDEM process. The main novelty is as follows: we are interested in the case when the \( \omega = \omega_i \in \Omega \) are i.i.d. r.v.'s and may take negative values satisfying the Cramer's condition \( \mathbb{E}[\exp(p\omega_-T)] < \infty \) for some \( p > \alpha \) and \( \omega_- = \max(-\omega, 0) \). Then, the model is defined by

\[
Y(t) = \sum_{i=1}^{N(t)} X_i e^{-\omega_i(t-T_i)}, \quad \forall \ t \geq 0.
\]

(5)

Here again, we can assume the the \( (X_i)_{i \geq 1} \) are asymptotically independent and identically regularly varying random variables. In dietary risk assessment, it makes sense to consider such random elimination parameter to take into account interactions between different human organs. Thus, \( \omega \) can be seen as a "inhibitor factor", for positive values of \( \omega \), or contrariwise, a "catalytic factor" for negative values of \( \omega \). In insurance, these Exp-SNP are often used and the parameter \( \omega_i = \omega \) can be seen as an accumulation (resp. discount) factor when \( \omega \) is a strictly negative (resp. positive) constant. Here the model is such that usually a discount factor applies on the risk except in some cases when it is the opposite and there is accumulation of the risk.

Assuming an homogeneous Poisson process on the distribution of claims instants such that \( \lambda(s) = \lambda \) for all \( 0 < s \leq t \), we obtain explicit formula for all the risk measures. Precisely,

Corollary 20. Let \( Y(t) \) follow the KDEM defined in [6] with random elimination parameter \( \omega \) such that \((H0')- (H1)-(H2)\) hold. Then we have \( \theta = \alpha \frac{\mathbb{E}[^2\omega]}{\mathbb{E}[\omega]} \) for \( \omega > 0 \) a.s., \( \theta = \alpha \omega_-\) if \( \mathbb{P}(\omega < 0) > 0 \).
and \( \omega \) constant, and for each risk indicator

\[
\mathbb{P}(Y(T) > x) \xrightarrow{x \to \infty} \lambda \mathbb{E}\Omega \left[ \frac{1 - e^{-\alpha \omega T}}{\omega \alpha} \right] F_X(x),
\]

\[
\psi(x, T) \xrightarrow{x \to \infty} \lambda \left( T \mathbb{P}(\omega > 0) + \mathbb{E} \left[ \frac{1 - e^{-\alpha \omega T}}{\omega \alpha} \mathbb{I}_{\{\omega \leq 0\}} \right] \right) F_X(x),
\]

\[
ETOT(x) \xrightarrow{x \to \infty} \frac{T \mathbb{P}(\omega > 0) + \mathbb{E} \left[ \frac{1 - e^{-\alpha \omega T}}{\omega \alpha} \mathbb{I}_{\{\omega \leq 0\}} \right]}{(\omega \alpha)^2},
\]

\[
IES(x) \xrightarrow{x \to \infty} \lambda \gamma \mathbb{E}\Omega \left[ \frac{(\omega \alpha T + e^{-\omega T\alpha} - 1)}{(\omega \alpha)^2} \right] F_X(x).
\]

Note that we obtained an explicit and understandable formulae for the extremal index. In dietary risk assessment, the elimination parameter \( \omega \) is most of the time chosen as a positive constant. Then, when \( x \) is large, \( \theta = \alpha \omega \) and one can estimate the tail index \( \alpha \) with usual statistical methods like the Hill estimator. As mentioned before, it could make sense that the elimination parameter may vary being random and may take negative values. Nonetheless, estimate its first and second moments seems to be a more difficult task and is left for further investigations.

**Proof.** Note that the only difficulty is the computation of the ruin probability. Indeed, it is enough to take the expectation regarding \( \omega \) and to apply formula given above to get the others risk indicators.

Remind that the ruin probability deals with the maxima of \( S \) which necessarily arise either on the skeleton, *i.e.* on the claims instants \( T_i \)'s or between \( T \) and the last intake instant \( T_{N(T)} \). Then, we have

\[
\psi(x, T) = \max \left\{ \max_{1 \leq k \leq N(T)} \sum_{i=1}^{k} e^{-\omega_i(T_k - T_i)} X_i, \sum_{i=1}^{N(T)} e^{-\omega_i(T - T_i)} X_i \right\}.
\]

Note that,

\[
\sum_{k=1}^{N(T)} ||A_k(N(T))||_{\infty}^\alpha = \sum_{k=1}^{N(T)} \max_j \left\{ e^{-\omega_j(T - T_k)} e^{-\omega_k(T - T_j)} \right\}^\alpha.
\]

We obtain

\[
\mathbb{E} \left[ \sum_{k=1}^{N(T)} ||A_k(N(T))||_{\infty}^\alpha \right] = \mathbb{E} \left[ \sum_{k=1}^{N(T)} \mathbb{I}_{\{\omega_k > 0\}} + e^{-\omega_k(T - T_k)} \mathbb{I}_{\{\omega_k \leq 0\}} \right]^\alpha
\]

\[
= \mathbb{E} \left[ \sum_{k=1}^{N(T)} \mathbb{P}(\omega_k > 0) + e^{-\alpha \omega(T - V_k)} \mathbb{I}_{\{\omega_k \leq 0\}} \right]
\]

\[
= \mathbb{E} [N(T)] \mathbb{P}(\omega_1 > 0) + \mathbb{E} \left[ e^{-\alpha \omega_1 T} \left( \int_0^T e^{-\alpha \omega_1 t} dt \right) \mathbb{I}_{\{\omega_1 \leq 0\}} \right]
\]

\[
= \mathbb{E} [N(T)] \mathbb{P}(\omega_1 > 0) + \mathbb{E} \left[ \frac{1 - e^{-\alpha \omega_1 T}}{\alpha \omega_1 T} \mathbb{I}_{\{\omega_1 \leq 0\}} \right].
\]

The desired result follows.

\[ \square \]

Note that we can also deal with strictly concave functions \( h_j(\cdot, T) \) by considering the new arrival times corresponding to the delayed maxima. However, the associated counting process is no longer a Poisson process and the constants are in general less explicit.
Remark 21. Note that for the Exp-SNP with constant $\omega$, the asymptotic ruin equivalent $\psi^*(x, T) \sim \lambda T \mathbb{F}(x)$ does not depend on the distribution of $\omega$. We have
\[
\lim_{x \to \infty} \frac{\psi(x, T)}{\psi^*(x, T)} = \mathbb{P}(\omega > 0) + \mathbb{E} \left[ \frac{1 - e^{-\alpha \omega T}}{T \omega} \mathbb{1}_{\{\omega \leq 0\}} \right] \geq \frac{1 + \mathbb{E}[e^{-\alpha \omega T}]}{2}.
\]
Notice that the original KDEM with r.v. $\omega$ has been defined in [6] by the recursive equation
\[
Y_{T_{j+1}} = \exp(-\omega_{j+1} \Delta T_{j+1}) Y_{T_j} + X_{T_{j+1}}, \quad j \geq 0,
\]
with $\Delta T_{j+1} = T_{j+1} - T_j$. This model is equivalent to KDEM with rate 1 and with inter-arrivals $\omega_{j+1} \Delta T_{j+1}$. This process converges to a stationary solution under $\mathbb{E}[\omega] > 0$ that is assumed from now, see [9]. Applying Remark 14 we obtain the ruin probability for that model
\[
\lim_{x \to \infty} \tilde{\psi}(x, t) = \mathbb{P}(X_1 > x) = \lambda T \mathbb{E}[\omega].
\]

Remark 22. Let us denote for all $n \in \mathbb{N}$, $Y_{T_{n+1}} = Y_{n+1}$, the chain on jump instants. Then, the embedded chain of the KDEM process with a constant elimination parameter is defined by
\[
Y_{n+1} = e^{-\omega \Delta T_{n+1}} Y_n + X_{n+1}.
\]
Then, thanks to [24], it follows that
\[
\theta = 1 - \mathbb{E}[e^{-\alpha \omega \Delta T}].
\]
If $\Delta T$ is exponentially distributed with rate $\lambda$,
\[
\mathbb{E}[e^{-\alpha \omega \Delta T}] = \frac{\lambda}{\lambda + \alpha \omega},
\]
and we have
\[
\theta = \frac{\alpha \omega}{\lambda + \alpha \omega}.
\]
Remark that the result differs from ours. A coefficient $1/(\lambda + \alpha \omega)$ appears and no interpretation or comparison between the extremal index for discrete-time series and its continuous equivalent is possible. However, the inverse of extremal index for discrete-time series gives, in average, the number of extremes by cluster. Then, the cluster are roughly of size $(1 + \lambda^{-1} \alpha \omega)/\alpha \omega$. When $\lambda \to \infty$, which corresponds to expand time to move from discrete to continuous setting, it converges to $\alpha \omega$ and we recover our result regarding the continuous version.

To conclude, in many configurations, under (H0'), we can explicitly derive the constant $\sum_{k=1}^{N} \|A_k(N)\|_1$, especially with respect to $\| \cdot \|_1$ and $\| \cdot \|_\infty$ which provide interesting equivalents to obtain risk indicators. We used it to compute the tail process, the ruin probability, the ETOT and the IES but our result can be applied on many other risk measures like Gerber-Shiu measures. In this paper, we have proposed to focus on SNP because it plays a leading role in risk theory but note that modifying the matrix $A(N)$, our method can be applied on several others stochastic processes. Finally, note that we can extend the previous results when $N$ is not a Poisson process but admits some finite moments so that Lemma [4] holds.

5. Proofs of the main results

5.1. Preliminaries. We begin by providing some useful properties to prove Propositions [8] and [9] and Theorems [10] and [11].

Remark 23. Results presented throughout the paper remain valid for any norm $\| \cdot \|$ such that (H3) holds. For any $n \in \mathbb{N}$, and $x > 0$, we have
\[
\mathbb{P}(\|X(n)\|_\infty > x) \leq \mathbb{P}(\|X(n)\| > x) \leq \mathbb{P}(\|X(n)\|_1 > x).
\]
We will use several times the following result known as Potter’s bound.
Lemma 26. Let $\mathcal{F} \in \text{RV}_{-a}$. Under (H0), there exists $\epsilon > 0$ such that $\mathbb{E}[N^{a+\epsilon+1}] < \infty$ and there exist $x_0 > 0$, $c > 1$ such that for all $y \geq x \geq x_0$, we have
\[
c^{-1}(y/x)^{-\alpha-\epsilon} \leq \frac{\mathcal{F}(y)}{\mathcal{F}(x)} \leq c(y/x)^{-\alpha+\epsilon}.
\]

Proof. See [20]. □

Let us provide a technical lemma useful in the proofs:

Lemma 25. Let $X(n) = (X_1, X_2, \ldots, X_n)$ be a sequence such that (H1)-(H2) hold. Let $f$ and $g$ be strictly positive functions such that for all $n \in \mathbb{N}^*$, $f(n) \leq g(n) \leq 1$. Then, for any fixed $n \geq 1$ and $\epsilon > 0$, there exists $b(x) \to 0$ such that
\[
\sum_{i=1, i \neq j}^{n} \frac{\mathbb{P}(X_i > f(n)x, X_j > g(n)x)}{\mathbb{P}(X_j > x)} \leq f(n)^{-\alpha+\epsilon}n^2b(x).
\]

Proof. Let $1 \leq i \neq j \leq n$, with $j \geq 1$ and $n \in \mathbb{N}^*$. Then, using Potter’s bound, for $x$ sufficiently large
\[
\sum_{i=1, i \neq j}^{n} \frac{\mathbb{P}(X_i > f(n)x, X_j > g(n)x)}{\mathbb{P}(X_j > x)} \leq \sum_{i=1, i \neq j}^{n} \frac{\mathbb{P}(X_i > f(n)x, X_j > f(n)x)}{\mathbb{P}(X_j > f(n)x)}
\]
\[
\leq c \sum_{i=1, i \neq j}^{n} f(n)^{-\alpha+\epsilon} \frac{\mathbb{P}(X_i > f(n)x, X_j > f(n)x)}{\mathbb{P}(X_j > f(n)x)}
\]
\[
\leq c f(n)^{-\alpha+\epsilon} \left( \sup_{i,j} \frac{\mathbb{P}(X_i > f(n)x, X_j > f(n)x)}{\mathbb{P}(X_j > f(n)x)} \right) \left( \sup_{i,j} \frac{\mathbb{P}(X_i > f(n)x)}{\mathbb{P}(X_j > f(n)x)} \right)
\]

which combined with (H2) concludes the proof. □

The following lemma plays a leading role in the sequel. It can be seen as an uniform integrability condition which allows in the main body of Propositions 6 and 7 to integrate with respect to $N$; see [5], Section 3.

Lemma 26. Let $N$ be a random length satisfying (H0). Let $X = (X_1, X_2, \ldots) \in \mathbb{R}^{\infty}$ be a sequence such that (H1)-(H2) hold. Let $A = (a_{i,j})_{i,j \geq 1}$ be the double indexed sequence of the coefficients satisfying (H4) and define $\mathbb{E}_{A}[\cdot]$ (respectively $\mathbb{P}_{X}[\cdot]$) the expectation (resp. the probability) with respect to $A$ (resp. $X$). Then, for any fixed $n_0 \in \mathbb{N}^*$ and for any norm $\| \cdot \|$ such that (H3) holds, we have the following statement:
\[
\lim_{n_0 \to \infty} \sup_{x > 0} \left( \mathbb{E}_{A} \left[ \sum_{n=n_0+1}^{\infty} \mathbb{P}(N = n) \frac{\mathbb{P}(\|A(n)X(n)\| > x)}{\mathbb{P}(X_1 > x)} \right] \right) = 0.
\]

Proof. Note first that
\[
I(x) = \sup_{x > 0} \left( \mathbb{E}_{A} \left[ \sum_{n=n_0+1}^{\infty} \mathbb{P}(N = n) \frac{\mathbb{P}(\|A(n)\| \|X(n)\| > x)}{\mathbb{P}(X_1 > x)} \right] \right)
\]
\[
\leq \mathbb{E}_{A} \left[ \sup_{x > 0} \left( \sum_{n=n_0+1}^{\infty} \mathbb{P}(N = n) \frac{\mathbb{P}(\|A(n)\| \vee 1 \|X(n)\| > x)}{\mathbb{P}(X_1 > x)} \right) \right]
\]
where \((a \lor b) = \max(a, b)\) for any \(a, b \in \mathbb{R}^+\). For a fixed \(x_0 > 0\) defined as in Proposition 24, denoting \(y = x_0(\|A(n)\| \lor 1)\), we have

\[
I(x) \leq \mathbb{E}_A \left[ \sup_{x > 0} \left( \sum_{n=n_0+1}^{\infty} \mathbb{P}(N = n) \frac{\mathbb{P}(\|A(n)\| \lor 1) |X(n)| > x)}{\mathbb{P}(X_1 > x)} \right) \right] + \mathbb{E}_A \left[ \sup_{x > 0} \left( \sum_{n > x/y \lor n_0}^{\infty} \mathbb{P}(N = n) \frac{\mathbb{P}(\|A(n)\| \lor 1) |X(n)| > x)}{\mathbb{P}(X_1 > x)} \right) \right]
\]

\[
\leq \mathbb{E}_A \left[ \sup_{x > ny} \left( \sum_{n=n_0+1}^{\infty} \mathbb{P}(N = n) \frac{\mathbb{P}(\|A(n)\| \lor 1) |X(n)| > x)}{\mathbb{P}(X_1 > x)} \right) \right] + \mathbb{E}_A \left[ \sup_{x > 0} \left( \mathbb{P}(N > (x/y \lor n_0)) \frac{\mathbb{P}(X_1 > x)}{\mathbb{P}(X_1 > x)} \right) \right]
\]

\[
\leq I_1(x) + I_2(x).
\]

Let us first investigate \(I_1(x)\). For every fixed \(x > 0\) and \(n > 0\), we have

\[
\mathbb{E}_A [\mathbb{P}(\|A(n)\| \lor 1) |X(n)| > x)] \leq \mathbb{E}_A [\mathbb{P}(\|X(n)\|_1 > x/(\|A(n)\| \lor 1))]
\]

\[
\leq \mathbb{E}_A \left[ \sum_{i=1}^{n} \mathbb{P}_{X_1}(X_i > x/n(\|A(n)\| \lor 1)) \right]
\]

\[
= n\mathbb{E}_A [\mathbb{P}_{X_1}(X_1 > x/n(\|A(n)\| \lor 1))].
\]

Then,

\[
I_1(x) \leq \mathbb{E}_A \left[ \sup_{x > ny} \left( \sum_{n=n_0+1}^{\infty} n\mathbb{P}(N = n) \frac{\mathbb{P}_{X_1}(X_1 > x/n(\|A(n)\| \lor 1))}{\mathbb{P}(X_1 > x)} \right) \right].
\]

Using the Potter’s bound, there exists \(c > 1\) independent of \(y \geq 1\) such that

\[
\sup_{x \geq ny} \frac{\mathbb{P}_{X_1}(X_1 > x/n(\|A(n)\| \lor 1))}{\mathbb{P}(X_1 > x)} \leq cn^{\alpha + \varepsilon}(\|A(n)\|^{\alpha + \varepsilon} \lor 1).
\]

It follows from (H4) that

\[
I_1(x) \leq c \sum_{n=n_0+1}^{\infty} \mathbb{P}(N = n) n^{\alpha + 1 + \varepsilon} \mathbb{E} \left[ (\|A(N)\|^{\alpha + \varepsilon} \lor 1)|N = n| \right] \rightarrow 0.
\]

We focus now on \(I_2(x)\). From Markov inequality, for any \(x > 0\) and any \(\varepsilon > 0\), under (H0), there exists a constant \(c > 0\) such that

\[
\mathbb{E}_A[\mathbb{P}(N > (x/y \lor n_0))] \leq \mathbb{E}_A \left[ \frac{\mathbb{E}[N^{\alpha + \varepsilon}]}{(x/y \lor n_0)^{\alpha + \varepsilon}} \right] \leq c\mathbb{E}_A \left[ \frac{1}{(x/y \lor n_0)^{\alpha + \varepsilon}} \right].
\]
Moreover, we have
\[
E_{\mathcal{A}} \left[ \sup_{x \leq n_0} \frac{\mathbb{P}(N > (x/y \vee n_0))}{\mathbb{P}(X_1 > x)} \right] \leq c \left( E_{\mathcal{A}} \left[ \sup_{x \leq n_0} \frac{(x/y \vee n_0)^{-\alpha - \epsilon}}{\mathbb{P}(X_1 > x)} \right] + E_{\mathcal{A}} \left[ \sup_{x \geq n_0} \frac{(x/y \vee n_0)^{-\alpha - \epsilon}}{\mathbb{P}(X_1 > x)} \right] \right)
\]
\[
\leq c \left( E_{\mathcal{A}} \left[ n_0^{-\alpha - \epsilon} \mathbb{P}(X_1 > n_0) \right] + E_{\mathcal{A}} \left[ \sup_{x \geq n_0} \frac{(y/x)^{\alpha + \epsilon}}{\mathbb{P}(X_1 > x)} \right] \right)
\]
Notice that that from (H4) the moments of order \(\alpha + \epsilon\) of \(\|A\|\) are finite and so \(E[y^{\alpha+\epsilon}] < \infty\). We use again the Potter’s bound and, for a possibly different constant \(c > 0\) (independent of \(y > 1\)) and \(n_0\) sufficiently large, we obtain
\[
I_2(x) \leq cE_{\mathcal{A}} \left[ y^{\alpha + \epsilon} \right] \left( \frac{n_0^{\alpha + \epsilon}}{\mathbb{P}(X_1 > n_0)} + \sup_{x \geq n_0} \frac{x^{-\alpha - \epsilon}}{\mathbb{P}(X_1 > x)} \right) \xrightarrow{n_0 \to \infty} 0.
\]
We finally obtain
\[
\lim_{n_0 \to \infty} I(x) = 0
\]
which concludes the proof. \(\square\)

5.2. Proof of Proposition 6

We first state a lemma which can be seen as a generalization of a well-known property for i.i.d. regularly varying r.v.’s with respect to the infinite norm \(\| \cdot \|_{\infty}\), which means that the maximum of a sequence satisfying (H1) is reached just by one coordinate. Note the crucial role of the uniform asymptotic independence condition (H2) in the sequel.

**Lemma 27.** Let \(X(n) = (X_1, X_2, \ldots, X_n)\) be a sequence of r.v.’s such that (H1)-(H2) hold and \(\| \cdot \|\) satisfies (H3). Then,
\[
\lim_{x \to \infty} \frac{\mathbb{P}(\|X(n)\| > x)}{n\mathbb{P}(X_1 > x)} = 1,
\]
for any fixed \(n \geq 1\).

**Proof.** We proceed by upper and lower bounding the quantity
\[
A(x) = \frac{\mathbb{P}(\|X(n)\| > x) - n\mathbb{P}(X_1 > x)}{n\mathbb{P}(X_1 > x)}.
\]
From Remark 23 under (H3), it is enough to investigate the lower (respectively the upper) bound with respect to \(\| \cdot \|_{\infty}\) (resp. \(\| \cdot \|_1\)). For the lower bound, using the Bonferroni bound, for any fixed \(n \geq 1\) and \(x > 0\), we have
\[
\mathbb{P}(\|X(n)\|_{\infty} > x) = \mathbb{P} \left( \bigcup_{i=1}^{n} X_i > x \right) \geq n\mathbb{P}(X_1 > x) - \sum_{i=1, i \neq j}^{n} \mathbb{P}(X_i > x, X_j > x).
\]
Then, from Lemma 25 and Remark 23 it follows that
\[
A(x) \geq - \sum_{i=1, i \neq j}^{n} \frac{\mathbb{P}(X_i > x, X_j > x)}{\mathbb{P}(X_j > x)} \xrightarrow{x \to \infty} 0.
\]
For the upper bound, let us consider \(\varepsilon\) such that \(\frac{1}{2} < \varepsilon < 1\). Then, for all \(x > 0\) and \(n \geq 1\),
\[
\mathbb{P}(\|X(n)\|_1 > x) = \mathbb{P} \left( \sum_{i=1}^{n} X_i > x \right) \leq \mathbb{P} \left( \bigcup_{i=1}^{n} X_i > \varepsilon x \right) + \mathbb{P} \left( \sum_{i=1}^{n} X_i > x, \bigcap_{j=1}^{n} \{X_j \leq \varepsilon x\} \right) = A_1(\varepsilon, x) + A_2(\varepsilon, x).
\]
Using an union bound again and (H1), we obtain
\[
\limsup_{x \to \infty} \frac{A_1(\varepsilon, x)}{\sum_{i=1}^{n} \mathbb{P}(X_i > x)} \leq \limsup_{x \to \infty} \frac{\sum_{i=1}^{n} \mathbb{P}(X_i > \varepsilon x)}{\sum_{i=1}^{n} \mathbb{P}(X_i > x)} = \varepsilon^{-\alpha}.
\]
Letting \(\varepsilon \to 1^-\), we obtain
\[
\limsup_{x \to \infty} \frac{A_1(\varepsilon, x)}{\sum_{i=1}^{n} \mathbb{P}(X_i > x)} \leq 1
\]
which implies that
\[
\limsup_{x \to \infty} \mathbb{P} (\|X(n)||_1 > x) - \sum_{i=1}^{n} \mathbb{P}(X_i > x) \leq \limsup_{\varepsilon \to 1^-} \limsup_{x \to \infty} A_2(\varepsilon, x).
\]
On the other hand, we have
\[
A_2(\varepsilon, x) = \mathbb{P} \left( \sum_{i=1}^{n} X_i > x, \bigcap_{j=1}^{n} (X_j \leq \varepsilon x), \max_{1 \leq k \leq n} X_k > \frac{x}{n} \right)
\]
\[
\leq \mathbb{P} \left( \sum_{i=1}^{n} X_i > x, X_k \leq \varepsilon x, X_k > \frac{x}{n} \right)
\]
\[
\leq \sum_{k=1}^{n} \mathbb{P} \left( \sum_{i=1}^{n} X_i > (1 - \varepsilon)x, X_k > \frac{x}{n} \right)
\]
\[
\leq \sum_{k=1}^{n} \sum_{i=1, i \neq k}^{n} \mathbb{P} \left( X_i > \frac{(1 - \varepsilon)x}{n - 1}, X_k > \frac{x}{n} \right).
\]
Besides, applying Lemma 25 with \(f(n) = \frac{1 - \varepsilon}{n - 1}\) and \(g(n) = \frac{x}{n}\) we obtain
\[
\limsup_{x \to \infty} A(x) \leq \limsup_{x \to \infty} \frac{A_2(\varepsilon, x)}{\sum_{i=1}^{n} \mathbb{P}(X_i > x)} \leq \limsup_{x \to \infty} \frac{\sum_{k=1}^{n} \sum_{i=1, i \neq k}^{n} \mathbb{P} \left( X_i > \frac{(1 - \varepsilon)x}{n - 1}, X_k > \frac{x}{n} \right)}{\sum_{i=1}^{n} \mathbb{P}(X_i > x)}
\]
\[
\leq \limsup_{x \to \infty} \sum_{k=1}^{n} \sum_{i=1, i \neq k}^{n} \frac{\mathbb{P} \left( X_i > \frac{(1 - \varepsilon)x}{n - 1}, X_k > \frac{x}{n} \right)}{\mathbb{P}(X_k > x)}
\]
\[
= 0.
\]
Collecting the bounds and using a sandwich argument leads to
\[
\lim_{x \to \infty} A(x) = 0
\]
for any fixed \(n \in \mathbb{N}^*\), which concludes the proof. \(\square\)

**Proof of Proposition 6.** From Lemma 25, for every fixed \(n_0 > 0\), we have
\[
\sum_{n=1}^{n_0} \mathbb{P}(N = n) \frac{\mathbb{P}(\|X(n)||_1 > x)}{\mathbb{P}(X_1 > x)} \to \lim_{x \to \infty} \sum_{n=1}^{n_0} n \mathbb{P}(N = n).
\]
Besides, under \((\text{H0})-(\text{H3})\), taking \(A(n) = I_n\), with \(I_n\) the identity matrix of size \(n \times n\), the assumptions of Lemma 26 hold. Then, from Remark 23

\[
\lim_{n_0 \to \infty} \sup_{x > 0} \sum_{n = n_0 + 1}^{\infty} \mathbb{P}(N = n) \frac{\mathbb{P}(\|X(n)\| > x)}{\mathbb{P}(X_1 > x)} = 0,
\]

for any norm \(\| \cdot \|\) such that \((\text{H3})\) holds which insures the uniform integrability with respect to \(N\). Letting \(n_0 \to \infty\) in the first expression concludes the proof. \(\square\)

5.3. Proof of Proposition 27 Let \(X(n) = (X_1, \ldots, X_n)\) be a sequence such that \((\text{H1})-(\text{H2})\) hold and let \(\| \cdot \|\) satisfying \((\text{H3})\). We need the following characterization.

\[(6) \quad \mathcal{L} \left( \frac{X(n)}{\|X(n)\|} \mid \|X(n)\| > x \right) \xrightarrow{x \to \infty} \mathcal{L}(\Theta(n)),\]

with \(\Theta(n)\) which does not depend on the choice of the norm \(\| \cdot \|\). Specifically \(\mathbb{P}(\Theta(n) = e_j) = n^{-1}\) which is consistent with Remark 8. We did not find a proper reference of this simple result and its proof follows: by asymptotical independence, the support of the spectral measure is concentrated on the canonical basis \(\mathbb{U}_n\) and the measure is fully characterized by the probability \(p_j = \mathbb{P}(\Theta(n) = e_j) = \mathbb{P}(Y_j(n) \geq 1)\) where \(Y_j(n) = \Theta_j(n)Y(n)\), \(1 \leq j \leq n\). By definition of \(\Theta(n)\), we also have \(\mathbb{P}(Y_j(n) \geq 1) = \lim_{x \to \infty} \mathbb{P}(X_j(n) \geq x \mid \|X(n)\| \geq x) = n^{-1}\) from Lemma 27.

Now, let \(X(N) = (X_1, \ldots, X_N)\) be a sequence such that \((\text{H0})-(\text{H2})\) hold. We first need to prove that for any norm \(\| \cdot \|\) satisfying \((\text{H3})\),

\[
\lim_{x \to \infty} \mathbb{P} \left( \left\| \frac{X(n)}{\|X(n)\|} - \Theta(n) \right\| > \epsilon \mid \|X(n)\| > x \right) = 0.
\]

From 19, the Skorohod’s representation theorem and Lemma 27, it follows that for any fixed \(n \in \mathbb{N}^*,\) for any norm \(\| \cdot \|\) such that \((\text{H3})\) holds and for any \(\epsilon > 0\), we have

\[
\lim_{x \to \infty} \mathbb{P} \left( \left\| \frac{X(n)}{\|X(n)\|} - \Theta(n) \right\| > \epsilon \mid \|X(n)\| > x \right) = 0.
\]

Then,

\[
\lim_{x \to \infty} \mathbb{P} \left( \left\| \frac{X(n)}{\|X(n)\|} - \Theta(n) \right\| > \epsilon \mid \|X(n)\| > x \right) = 0.
\]

Moreover,

\[
\mathbb{P} \left( \left\| \frac{X(n)}{\|X(n)\|} - \Theta(n) \right\| > \epsilon \mid \|X(n)\| > x \right) \leq \frac{\mathbb{P}(\|X(n)\| > x)}{\mathbb{P}(X_1 > x)}\mathbb{P}(N = n) = 0.
\]

and the uniform integrability criteria holds, which leads to

\[
\lim_{x \to \infty} \sum_{n=1}^{\infty} \mathbb{P} \left( \left\| \frac{X(n)}{\|X(n)\|} - \Theta(n) \right\| > \epsilon \mid \|X(n)\| > x \right) \mathbb{P}(N = n) = 0.
\]

Finally, thanks to Proposition 24 we know that \(\|X(N)\|\) is regularly varying, and for any \(\epsilon > 0\) we have

\[
\mathbb{P} \left( \left\| \frac{X(N)}{\|X(N)\|} - \Theta(N) \right\| > \epsilon \mid \|X(N)\| > x \right) \xrightarrow{x \to \infty} 0.
\]
Theorem 11. From Theorem 10, if we assume (H5)

\[ \lim_{n \to \infty} P \left( \|X(N)\|^{-1}X(N) \in \cdot \mid \|X(N)\| > x \mid N = n \right) \mathbb{P}(N = n) \]

\[ = \lim_{n \to \infty} \sum_{n=1}^{\infty} \mathbb{P}(\|X(N)\| > x \mid N = n) \mathbb{P}(N = n) \]

\[ = \sum_{n=1}^{\infty} \mathbb{P}(\|X(n)\|^{-1}X(n) \in \cdot \mid X(n) > x) \mathbb{P}(N = n) \]

\[ = \sum_{n=1}^{\infty} \mathbb{P}(\|X(n)\|^{-1}X(n) \in \cdot \mid X(n) > x) \mathbb{P}(N = n) / \mathbb{P}(X_1 > x) \]

Then, from what precedes and Lemma 27, we get for all \( j \geq 1 \)

\[ \mathbb{P}(\|X(N)\|^{-1}X(N) = e_j \mid \|X(N)\| > x) \sim \frac{\sum_{n=1}^{\infty} \mathbb{P}(N = n)}{\sum_{n=1}^{\infty} n \mathbb{P}(N = n)} \sim \frac{\mathbb{P}(N \geq j)}{\mathbb{E}[N]}, \]

and the desired result follows.

5.4. Proof of Theorem 10 From Proposition 9, for any fixed \( n_0 \), we have

\[ \sum_{n=1}^{n_0} \frac{\mathbb{P}(\|C(n)\| > x) \mathbb{P}(N = n)}{\mathbb{P}(X_1 > x)} \xrightarrow{x \to \infty} \sum_{n=1}^{n_0} a \sum_{k=1}^{n} \|A_k(n)\|^\alpha \mathbb{P}(N = n). \]

From Lemma 26 the uniform integrability of \( \mathbb{P}(\|C(n)\| > x)/\mathbb{P}(X_1 > x) \) with respect to \( N \) holds, one can let \( n_0 \) tends to \( +\infty \) above which concludes the proof.

5.5. Proof of Theorem 11. Let us use a similar but slightly but more evolved reasoning to prove Theorem 11. From Theorem 11 if we assume (H5), as the \( a_{i,j} \) are not all identically null we have

\[ \lim_{x \to \infty} \frac{\mathbb{P}(\|C(N)\| > x)}{\mathbb{P}(X_1 > x)} = \mathbb{E} \left[ \sum_{j=1}^{N} \|A_j(N)\|^\alpha \right] > 0, \]

and then \( \|C(N)\| \) is regularly varying. It remains to prove the existence of the spectral measure. From Proposition 8 we have

\[ P_{x,n}(\cdot) = \frac{\mathbb{P}(\|C(N)\|^{-1}C(N) \in \cdot \mid C(N) > x, N = n)}{\mathbb{P}(\|C(N)\| > x, N = n)} \]

\[ = \frac{\mathbb{P}(\|C(n)\|^{-1}C(n) \in \cdot \mid C(n) > x, N = n)}{\mathbb{P}(\|C(n)\| > x, N = n)} \]

\[ = \frac{\mathbb{P}(\|C(n)\|^{-1}C(n) \in \cdot \mid C(n) > x) \mathbb{P}(X_1 > x)}{\mathbb{P}(\|C(n)\| > x)}. \]

Consider \( n \) sufficiently large such that \( \mathbb{E}[\|A(n)\Theta(n)\|^\alpha] > 0 \). Applying the regular varying properties stated in Proposition 9 we have

\[ \lim_{x \to \infty} \frac{\mathbb{P}(X_1 > x)}{\mathbb{P}(\|C(n)\| > x)} = \frac{1}{\mathbb{E}[\|A(n)\Theta(n)\|^\alpha n]}. \]
Then,
\[
\lim_{x \to \infty} P_{x,n}(\cdot) = \lim_{x \to \infty} \frac{P(\|A(n)X(n)\|^{-1}A(n)X(n) \in \cdot, \|A(n)X(n)\| > x)}{E[\|A(n)\Theta(n)\|^{\alpha}n] P(X_1 > x)}
\]
and, as \(X(n)\) is regularly varying we can apply the multivariate Breiman’s lemma to obtain
\[
\lim_{x \to \infty} P_{x,n}(\cdot) = \frac{E[\|A(n)\Theta(n)\|^{\alpha}n I_{\|A(n)\Theta(n)\|^{-1}A(n)\in \cdot}] n}{E[\sum_{k=1}^{\infty} \|A_k(n)\|^{\alpha} I_{\|A_k(n)\|^{-1}A_k(n)\in \cdot}] n}
\]
Now, for any norm \(\| \cdot \|\) such that \((H3)\) holds, we have
\[
P \left( \|C(n)\|^{-1}C(n) \in \cdot \mid \|C(n)\| > x \right) \leq \frac{P(\|C(n)\|_1 > x)}{P(X_1 > x)}
\]
and the uniform integrability condition of Lemma 2.6 is fulfilled which, combined with (7), leads to
\[
P \left( \|C(N)\|^{-1}C(N) \in \cdot \mid \|C(N)\| > x \right) \to_{x \to \infty} \frac{E \left[ \sum_{k=1}^{N} \|A_k(N)\|^{\alpha} I_{\|A_k(N)\|^{-1}A_k(n)\in \cdot} \right]}{E \left[ \sum_{k=1}^{N} \|A_k(N)\|^{\alpha} \right]}
\]
