LAPLACIANS ON METRIC GRAPHS: EIGENVALUES, RESOLVENTS AND SEMIGROUPS

VADIM KOSTRYKIN AND ROBERT SCHRADER

ABSTRACT. The main objective of the present work is to study the negative spectrum of (differential) Laplace operators on metric graphs as well as their resolvents and associated heat semigroups. We prove an upper bound on the number of negative eigenvalues and a lower bound on the spectrum of Laplace operators. Also we provide a sufficient condition for the associated heat semigroup to be positivity preserving.

1. INTRODUCTION

As suggested by the title, the main objective of the present work is to study the negative spectrum of (differential) Laplace operators on metric graphs as well as their resolvents and associated heat semigroups. Basic notions related to these operators are summarized in Section 2 below. More complete accounts can be found in [10], [12], [13].

It is well known (see, e.g., [7], [19]) that there are deep interrelations between properties of heat semigroups and spectral properties of their generators. More importantly, heat semigroups generated by Laplace-Beltrami operators on Riemannian manifolds carry a large amount of information on the geometry of the underlying manifolds. As for metric graphs some results in this direction can be found, e.g., in [22], [23]. Nevertheless, a systematic analysis of heat semigroups for Laplace operators on metric graphs is still missing. In this work we perform a first step in closing this gap.

Below we will prove an upper bound on the number of negative eigenvalues (Theorem 3.7) and a lower bound on the spectrum of Laplace operators (Theorem 3.10). In particular, the upper bound provides a very simple sufficient condition for the Laplace operator to be nonnegative. The lower bound improves a recent result by Kuchment [13].

Concerning resolvents and heat kernels we will establish sufficient conditions for them to be positivity preserving. To achieve this we will provide a closed expression for Green’s function in terms of the boundary conditions defining the corresponding Laplace operator. As a consequence for a class of boundary conditions associated with positive maximal isotropic subspaces (Definition 4.4 below) we prove positivity of Green’s function (see Theorems 4.6 and 5.1). The proof of Theorem 5.1 utilizes walks on a graph, a concept introduced in our paper [12] as a main technical tool for solving the inverse scattering

2000 Mathematics Subject Classification. 34B45, 34L15, 47D03.

Key words and phrases. Differential operators on metric graphs, eigenvalue problems, positivity preserving semigroups.
problem on metric graphs. By standard arguments these results imply that the associated heat semigroup is positivity preserving.

For earlier work on heat semigroups generated by Laplace operators on metric graphs and their application to spectral analysis we refer to [2], [4], [8], [9], [17], [18], [22], [23]. Green’s functions have been studied in [2], [3], [10], [20].

There is a well-known approach to prove the simplicity of the lowest eigenvalue based on the analysis of heat semigroups (see, e.g., [21]). Although we do not pursue this in detail, merely as an illustration, for a class of boundary conditions we prove simplicity of the lowest eigenvalue of Laplace operators on metric graphs without internal edges (see Proposition 6.4 below).

In Section 7 we consider Laplace operators on metric graphs with no internal edges, for which the heat kernel can be computed explicitly.

Acknowledgements. The authors are indebted to S. Fulling, H. Hofer, M. Karowski, W. Kirsch, M. Loss, and M. Taylor for useful comments. We thank the anonymous referees for careful reading of the manuscript and helpful suggestions. The participation of the first author (V.K.) at the conference “Quantum Graphs and Their Applications” held in the summer 2005 in Snowbird, Utah, USA has been supported by the Deutsche Forschungsgemeinschaft and by the National Science Foundation.

2. Basic Structures

In this section we revisit the theory of Laplace operators on a metric graph \( \mathcal{G} \). The material presented here is borrowed from our preceding papers [10] and [12].

A finite graph is a 4-tuple \( \mathcal{G} = (V, I, E, \partial) \), where \( V \) is a finite set of vertices, \( I \) is a finite set of internal edges, \( E \) is a finite set of external edges. Elements in \( I \cup E \) are called edges. The map \( \partial \) assigns to each internal edge \( i \in I \) an ordered pair of (possibly equal) vertices \( \partial(i) := \{v_1, v_2\} \) and to each external edge \( e \in E \) a single vertex \( v \). The vertices \( v_1 := \partial^-(i) \) and \( v_2 := \partial^+(i) \) are called the initial and terminal vertex of the internal edge \( i \), respectively. The vertex \( v = \partial(e) \) is the initial vertex of the external edge \( e \). If \( \partial(i) = \{v, v\} \), that is, \( \partial^-(i) = \partial^+(i) \) then \( i \) is called a tadpole. A graph is called compact if \( E = \emptyset \), otherwise it is noncompact.

Throughout the whole work we will assume that the graph \( \mathcal{G} \) is connected, that is, for any \( v, v' \in V \) there is an ordered sequence \( \{v_1 = v, v_2, \ldots, v_n = v'\} \) such that any two successive vertices in this sequence are adjacent. In particular, this implies that any vertex of the graph \( \mathcal{G} \) has nonzero degree, i.e., for any vertex there is at least one edge with which it is incident.

We will endow the graph with the following metric structure. Any internal edge \( i \in I \) will be associated with an interval \([0, a_i]\) with \( a_i > 0 \) such that the initial vertex of \( i \) corresponds to \( x = 0 \) and the terminal one - to \( x = a_i \). Any external edge \( e \in E \) will be associated with a semiline \([0, +\infty)\). We call the number \( a_i \) the length of the internal edge \( i \). The set of lengths \( \{a_i\}_{i \in I} \), which will also be treated as an element of \( \mathbb{R}^{|I|} \), will be denoted by \( a \). A compact or noncompact graph \( \mathcal{G} \) endowed with a metric structure is called a metric graph \((\mathcal{G}, a)\).

Given a finite graph \( \mathcal{G} = (V, I, E, \partial) \) with a metric structure \( a = \{a_i\}_{i \in I} \) consider the Hilbert space

\[
(2.1) \quad \mathcal{H} \equiv \mathcal{H}(\mathcal{E}, \mathcal{I}, a) = \mathcal{H}_E \oplus \mathcal{H}_I, \quad \mathcal{H}_E = \bigoplus_{e \in E} \mathcal{H}_e, \quad \mathcal{H}_I = \bigoplus_{i \in I} \mathcal{H}_i,
\]
where $\mathcal{H}_j = L^2(I_j)$ with

$$I_j = \begin{cases} [0, a_j] & \text{if } j \in \mathcal{I}, \\ [0, \infty) & \text{if } j \in \mathcal{E}. \end{cases}$$

Let $\overset{\circ}{I}_j$ be the interior of $I_j$, that is, $\overset{\circ}{I}_j = (0, a_j)$ if $j \in \mathcal{I}$ and $\overset{\circ}{I}_j = (0, \infty)$ if $j \in \mathcal{E}$.

In the sequel the letters $x$ and $y$ will denote arbitrary elements of the product set $\prod_{j \in \mathcal{E} \cup \mathcal{I}} \overset{\circ}{I}_j$.

By $D_j$ with $j \in \mathcal{E} \cup \mathcal{I}$ denote the set of all $\psi_j \in \mathcal{H}_j$ such that $\psi_j(x)$ and its derivative $\psi_j'(x)$ are absolutely continuous and $\psi_j''(x)$ is square integrable. Let $D^0_j$ denote the set of those elements $\psi_j \in D_j$ which satisfy

$$\begin{align*}
\psi_j(0) &= 0 & \text{for } j \in \mathcal{E} \\
\psi_j'(0) &= 0 & \text{for } j \in \mathcal{I}.
\end{align*}$$

Let $\Delta^0$ be the differential operator

$$\left(\Delta^0\psi\right)_j(x) = \frac{d^2}{dx^2} \psi_j(x), \quad j \in \mathcal{I} \cup \mathcal{E}$$

with domain

$$D^0 = \bigoplus_{j \in \mathcal{E} \cup \mathcal{I}} D^0_j \subset \mathcal{H}.$$
Let $A$ and $B$ be linear maps of $\mathcal{K}$ onto itself. By $(A, B)$ we denote the linear map from $d\mathcal{K} = \mathcal{K} \oplus \mathcal{K}$ to $\mathcal{K}$ defined by the relation

$$(A, B)(\chi_1 \oplus \chi_2) := A\chi_1 + B\chi_2,$$

where $\chi_1, \chi_2 \in \mathcal{K}$. Set

$$(2.8) \quad \mathcal{M}(A, B) := \ker (A, B).$$

**Theorem 2.1.** A subspace $\mathcal{M} \subset d\mathcal{K}$ is maximal isotropic if and only if there exist linear maps $A, B : \mathcal{K} \to \mathcal{K}$ such that $\mathcal{M} = \mathcal{M}(A, B)$ and

(i) the map $(A, B) : d\mathcal{K} \to \mathcal{K}$ has maximal rank equal to $|\mathcal{E}| + 2|\mathcal{I}|$.

(ii) $AB^\dagger$ is self-adjoint, $AB^\dagger = BA^\dagger$.

**Definition 2.2.** The boundary conditions $(A, B)$ and $(A', B')$ satisfying (2.9) are equivalent if the corresponding maximal isotropic subspaces coincide, that is, $\mathcal{M}(A, B) = \mathcal{M}(A', B')$.

The boundary conditions $(A, B)$ and $(A', B')$ satisfying (2.9) are equivalent if and only if there is an invertible map $C : \mathcal{K} \to \mathcal{K}$ such that $A' = CA$ and $B' = CB$ (see Proposition 3.6 in [12]).

By Lemma 3.3 in [12], a subspace $\mathcal{M}(A, B) \subset d\mathcal{K}$ is maximal isotropic if and only if

$$(2.10) \quad \mathcal{M}(A, B)\perp = \mathcal{M}(B, -A).$$

We mention also the equalities

$$(2.11) \quad \mathcal{M}(A, B)^\perp = \left[\ker (A, B)\right]^\perp = \text{Ran} (A, B)^\dagger,$$

$\mathcal{M}(A, B) = \text{Ran} (-B, A)^\dagger$.

In the terminology of symplectic geometry (see, e.g., Section 2.3 in [16]) the equalities (2.11) have the following interpretation: The matrix $(A, B)^\dagger$ is a (Lagrangian)frame for the maximal isotropic subspace $\mathcal{M}(A, B)^\perp$ and the matrix $(-B, A)^\dagger$ is a frame for $\mathcal{M}(A, B)$.

There is an alternative parametrization of maximal isotropic subspaces of $d\mathcal{K}$ by unitary transformations in $\mathcal{K}$ (see [11] and Proposition 3.6 in [12]). A subspace $\mathcal{M}(A, B) \subset d\mathcal{K}$ is maximal isotropic if and only if for an arbitrary $k \in \mathbb{R} \setminus \{0\}$ the operator $A + ikB$ is invertible and

$$(2.12) \quad \mathcal{S}(k; A, B) := -(A + ikB)^{-1}(A - ikB)$$

is unitary. Moreover, given any $k \in \mathbb{R} \setminus \{0\}$ the correspondence between maximal isotropic subspaces $\mathcal{M} \subset d\mathcal{K}$ and unitary operators $\mathcal{S}(k; A, B) \in U(|\mathcal{E}| + 2|\mathcal{I}|)$ on $\mathcal{K}$ is one-to-one. Therefore, we will use the notation $\mathcal{S}(k; \mathcal{M})$ for $\mathcal{S}(k; A, B)$ with $\mathcal{M}(A, B) = \mathcal{M}$.

There is a one-to-one correspondence between all self-adjoint extensions of $\Delta^0$ and maximal isotropic subspaces of $d\mathcal{K}$ (see [10], [12]). In explicit terms, any self-adjoint extension of $\Delta^0$ is the differential operator defined by (2.2) with domain

$$(2.13) \quad \text{Dom} (\Delta) = \{\psi \in \mathcal{D} | \psi \in \mathcal{M}\},$$

where $\mathcal{M}$ is a maximal isotropic subspace of $d\mathcal{K}$. Conversely, any maximal isotropic subspace $\mathcal{M}$ of $d\mathcal{K}$ defines through (2.13) a self-adjoint operator $\Delta(\mathcal{M}, g)$. If $\mathcal{I} = \emptyset$, we will simply write $\Delta(\mathcal{M})$. In the sequel we will call the operator $\Delta(\mathcal{M}, g)$ a Laplace operator on the metric graph $(\mathcal{G}, g)$. From the discussion above it follows immediately that any self-adjoint Laplace operator on $\mathcal{H}$ equals $\Delta(\mathcal{M}, g)$ for some maximal isotropic subspace $\mathcal{M}$. Moreover, $\Delta(\mathcal{M}, g) = \Delta(\mathcal{M}', g)$ if and only if $\mathcal{M} = \mathcal{M}'$. 
From Theorem 2.1 it follows that the domain of the Laplace operator \( \Delta(M, a) \) consists of functions \( \psi \in D \) satisfying the boundary conditions
\[
A \psi + B \psi' = 0,
\]
with \( (A, B) \) subject to (2.8) and (2.9). Here \( \psi \) and \( \psi' \) are defined by (2.5).

With respect to the orthogonal decomposition \( K = K_E \oplus K_I^+ \oplus K_I^- \) any element \( \chi \) of \( K \) can be represented as a vector
\[
\chi = \left( \begin{array}{c}
\chi_e \\
\chi_i^- \\
\chi_i^+
\end{array} \right),
\]
for \( e \in E \), \( i \in I \), \( i \in I \). Consider the orthogonal decomposition
\[
K = \bigoplus_{v \in V} L_v
\]
with \( L_v \) the linear subspace of dimension \( \deg(v) \) spanned by those elements \( 2.15 \) of \( K \) which satisfy
\[
\begin{align*}
\chi_e &= 0 & & \text{if } e \in E \text{ is not incident with the vertex } v, \\
\chi_i^- &= 0 & & \text{if } v \text{ is not an initial vertex of } i \in I, \\
\chi_i^+ &= 0 & & \text{if } v \text{ is not a terminal vertex of } i \in I.
\end{align*}
\]
Obviously, the subspaces \( L_{v_1} \) and \( L_{v_2} \) are orthogonal if \( v_1 \neq v_2 \).

Set \( dL_v := L_v \oplus L_v \cong C^{2 \deg(v)} \). Obviously, each \( dL_v \) inherits a symplectic structure from \( dK \) in a canonical way, such that the orthogonal decomposition
\[
\bigoplus_{v \in V} dL_v = dK
\]
holds.

**Definition 2.3.** Given the graph \( G = G(V, I, E, \partial) \), boundary conditions \( (A, B) \) satisfying (2.9) are called local on \( G \) if the maximal isotropic subspace \( M(A, B) \) of \( K \) has an orthogonal symplectic decomposition
\[
M(A, B) = \bigoplus_{v \in V} M(v),
\]
with \( M(v) \) being maximal isotropic subspaces of \( dL_v \).

Otherwise the boundary conditions are called non-local.

By Proposition 4.2 in [12], given the graph \( G = G(V, I, E, \partial) \), the boundary conditions \( (A, B) \) satisfying (2.9) are local on \( G \) if and only if there is an invertible map \( C : K \to K \) and linear transformations \( A(v) \) and \( B(v) \) in \( L_v \) such that the simultaneous orthogonal decompositions
\[
CA = \bigoplus_{v \in V} A(v) \quad \text{and} \quad CB = \bigoplus_{v \in V} B(v)
\]
are valid.

Given a graph \( G = (V, I, E, \partial) \) to any vertex \( v \in V \) we associate the graph \( G_v = (\{v\}, I_v, E_v, \partial_v) \) with the following properties
\[
\begin{align*}
(i) & \quad I_v = \emptyset, \\
(ii) & \quad \partial_v(e) = v \text{ for all } e \in E_v,
\end{align*}
\]
Example 2.4 (Standard boundary conditions). Given a graph \( \mathcal{G} \) with \( |V| \geq 2 \) and minimum degree not less than two, define the boundary conditions \( (A(v), B(v)) \) on \( \mathcal{G}_v \) for every \( v \in V \) by the \( \deg(v) \times \deg(v) \) matrices

\[
A(v) = \begin{pmatrix}
1 & -1 & 0 & \ldots & 0 & 0 \\
0 & 1 & -1 & \ldots & 0 & 0 \\
0 & 0 & 1 & \ldots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & \ldots & 1 & -1 \\
0 & 0 & 0 & \ldots & 0 & 0
\end{pmatrix}, \quad B(v) = \begin{pmatrix}
0 & 0 & 0 & \ldots & 0 & 0 \\
0 & 0 & 0 & \ldots & 0 & 0 \\
0 & 0 & 0 & \ldots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & \ldots & 0 & 0 \\
1 & 1 & 1 & \ldots & 1 & 1
\end{pmatrix}.
\]

Obviously, \( A(v)B(v)^\dagger = 0 \) and \( (A(v), B(v)) \) has maximal rank. Thus, for every \( v \in V \) the boundary conditions \( (A(v), B(v)) \) define self-adjoint Laplace operators \( \Delta(A(v), B(v)) \) on \( L^2(\mathcal{G}_v) \). The corresponding unitary matrices \( \Delta(\mathcal{G}_v) \) are given by

\[
[\mathcal{G}(k; A(v), B(v))]_{e,e'} = \frac{2}{\deg(v)} - \delta_{e,e'}
\]

with \( \delta_{e,e'} \) Kronecker symbol.

The boundary conditions \( (A(v), B(v)) \) induce standard local boundary conditions \( (A, B) \) on the graph \( \mathcal{G} \).

The following result is Corollary 5 in [13].

Lemma 2.5. Boundary conditions \( (A, B) \) satisfying 2.9 are equivalent to the boundary conditions \( (\widehat{A}, \widehat{B}) \) with

\[
\widehat{A} = P_{\text{Ker } B} + L, \quad \widehat{B} = P_{\text{Ker } B}^\perp,
\]

where \( P_{\text{Ker } B} \) is the orthogonal projection in \( K \) onto \( \text{Ker } B \), \( P_{\text{Ker } B}^\perp := \mathbb{I} - P_{\text{Ker } B} \) its complementary projection, and \( L : K \to K \) the self-adjoint operator given by

\[
L = (B|_{\text{Ran } B^\perp})^{-1} A P_{\text{Ker } B}^\perp.
\]

Note that \( \widehat{A}\widehat{B}^\dagger = L \) and \( \text{Ker } L \supset \text{Ker } B \).

In particular, if \( \text{Ker } B = \{0\} \) such that \( L = B^{-1}A \), then \( \mathcal{G}(k; A, B) = -\frac{L + ik}{L - ik} \) (cf. Proposition 3.19 in [12]).

Corollary 2.6. Assume that \( \det(A - \omega B) \neq 0 \) for some \( \omega > 0 \). Then \( \mathcal{G}(i\omega; A, B) \) is self-adjoint. If \( L \leq 0 \), then \( \mathcal{G}(i\omega; A, B) \) is a contraction for all \( \omega > 0 \).

Proof. The assumption \( \det(A - \omega B) \neq 0 \) combined with the fact that the subspace \( \text{Ker } B \) reduces the operator \( L \) implies that \( L - \omega \) is invertible. By Lemma 2.5 we have

\[
\mathcal{G}(i\omega; A, B) = \mathcal{G}(i\omega; \widehat{A}, \widehat{B}) = -P_{\text{Ker } B} - P_{\text{Ker } B}^\perp (L - \omega)^{-1}(L + \omega) P_{\text{Ker } B}^\perp
\]

\[
= -2P_{\text{Ker } B} - (L - \omega)^{-1}(L + \omega),
\]

\[
(iii) |\mathcal{E}_v| = \deg_\mathcal{G}(v), \text{ the degree of the vertex } v \text{ in the graph } \mathcal{G},
\]

(iv) there is an injective map \( \Psi_v : \mathcal{E}_v \to \mathcal{E} \cup \mathcal{I} \) such that \( v \in \partial \circ \Psi_v(e) \) for all \( e \in \mathcal{E}_v \).
which is self-adjoint. From (3.3) it follows that 
\[ \|\mathcal{G}(ix; A, B)\| = \max\{1, \|(L - \infty)^{-1}(L + \infty)\|\}. \]
If \( L \leq 0 \), then by the spectral theorem \( \|(L - \infty)^{-1}(L + \infty)\| \leq 1 \) for all \( \infty > 0 \). \( \Box \)

3. EIGENVALUES OF LAPLACE OPERATORS

If \( \psi = \{\psi_j\}_{j \in \mathcal{I} \cup \mathcal{E}} \in \mathcal{H} \) is an eigenfunction of the operator \( -\Delta(A, B, \overline{\alpha}) \) corresponding to the eigenvalue \( k^2 \in \mathbb{R} \setminus \{0\} \), then it is necessarily of the form

\[
\psi_j(x; k) = \begin{cases} 
  s_j e^{ik_j x} & \text{for } j \in \mathcal{E}, \\
  \alpha_j e^{ik_j x} + \beta_j e^{-ik_j x} & \text{for } j \in \mathcal{I}.
\end{cases}
\]

The vectors \( s = \{s_j\}_{j \in \mathcal{E}} \in \mathcal{K}_\mathcal{E}, \alpha = \{\alpha_i\}_{i \in \mathcal{I}} \in \mathcal{K}_\mathcal{I}^{(-)}, \) and \( \beta = \{\beta_i\}_{i \in \mathcal{I}} \in \mathcal{K}_\mathcal{I}^{(+)}, \) satisfy the homogeneous equation

\[
Z(k; A, B, \overline{\alpha}) \begin{pmatrix} s \\ \alpha \end{pmatrix} = 0
\]

with

\[
Z(k; A, B, \overline{\alpha}) = AX(k; \overline{\alpha}) + ikBY(k; \overline{\alpha}),
\]

where

\[
X(k; \overline{\alpha}) = \begin{pmatrix} I & 0 & 0 \\ 0 & I & I \\ 0 & e^{ik_2} & e^{-ik_2} \end{pmatrix}
\]

and

\[
Y(k; \overline{\alpha}) = \begin{pmatrix} I & 0 & 0 \\ 0 & I & -I \\ 0 & -e^{ik_2} & e^{-ik_2} \end{pmatrix}.
\]

The diagonal \(|\mathcal{I}| \times |\mathcal{I}|\) matrices \( e^{\pm ik_2} \) are given by

\[
[e^{\pm ik_2}]_{jk} = \delta_{jk} e^{\pm ik_2} \quad \text{for } j, k \in \mathcal{I}.
\]

The converse statement is also true and we have the following result.

**Lemma 3.1.** A \( \psi \) given by (3.1) is an eigenfunction of \(-\Delta(A, B, \overline{\alpha})\) corresponding to the eigenvalue \( k^2 \in \mathbb{R} \setminus \{0\} \) if and only if (3.2) possesses a nontrivial solution. The multiplicity of this eigenvalue is equal to \dim \ker Z(k; A, B, \overline{\alpha}).

**Proof.** If \( k^2 < 0 \), the claim is obvious, since \( \psi \in \text{Dom}(\Delta(A, B, \overline{\alpha})) \). If \( k^2 > 0 \), any solution of (3.2) satisfies \( s = 0 \) (see the proof of Theorem 3.1 in [10]). Therefore, \( \psi \in \text{Dom}(\Delta(A, B, \overline{\alpha})) \). \( \Box \)

As proven in [10] Theorem 3.1 the set of zeros of \( \det Z(k; A, B, \overline{\alpha}) \) is discrete.

Denote

\[
T(k; \overline{\alpha}) := \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & e^{ik_2} \\ 0 & e^{ik_2} & 0 \end{pmatrix}
\]

with respect to the orthogonal decomposition (3.3).

**Theorem 3.2.** Assume that \( \mathcal{I} \neq \emptyset \). Then \( \lambda = k^2 \neq 0 \) such that \( \det(A + ikB) \neq 0 \) is an eigenvalue of \(-\Delta(A, B, \overline{\alpha})\) with multiplicity \( m \) if and only if 1 is an eigenvalue of \( \mathcal{G}(k; A, B)T(k; \overline{\alpha}) \)

with geometric multiplicity \( m \).

If \( \mathcal{I} = \emptyset \), then \( \lambda = -x^2 < 0 \) is an eigenvalue of \(-\Delta(A, B)\) with multiplicity \( m \) if and only if 0 is an eigenvalue of \( A - xB \) with geometric multiplicity \( m \).
Remark 3.3. In [10] it is shown that \( \det(A + i k B) \neq 0 \) and \( \det(A - i k B) \neq 0 \) hold for all \( k > 0 \).

Proof. Observe that if \( \det(A + i k B) \neq 0 \), then
\[
AX(k; \underline{x}) + i k BY(k; \underline{x}) = (A + i k B)R_+(k; \underline{x}) + (A - i k B)R_-(k; \underline{x})
\]
(3.7)
where
\[
R_+(k; \underline{x}) := \frac{1}{2}[X(k; \underline{x}) + Y(k; \underline{x})] = \begin{pmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & e^{ik\underline{x}} \end{pmatrix},
\]

\[
R_-(k; \underline{x}) := \frac{1}{2}[X(k; \underline{x}) - Y(k; \underline{x})] = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & e^{ik\underline{x}} & I \end{pmatrix}.
\]

Hence, by Lemma 3.1 \( \begin{pmatrix} s \\ \alpha \\ \beta \end{pmatrix} \in \mathcal{K} \) is a nontrivial solution to (4.2) if and only if
\[
[I - \mathcal{G}(k; A, B)T(k; \underline{x})] \begin{pmatrix} s \\ \alpha \\ e^{-ik\underline{x}} \beta \end{pmatrix} = 0.
\]
(3.9)
If \( \mathcal{I} = \emptyset \), then equation (4.2) simplifies to \( (A + i k B)s = 0 \) with \( s \in \mathcal{K}_{\mathbb{C}} \). \( \square \)

3.1. Positive Laplacians. Let \( \mathcal{M} \subset \mathcal{K} \) be a maximal isotropic subspace. Let \( (A, B) \) be arbitrary boundary conditions satisfying \( \mathcal{M}(A, B) = \mathcal{M} \). Let \( n_+(AB^\dagger) \) and \( n_0(AB^\dagger) \) be the number of positive (negative, zero, respectively) eigenvalues of \( AB^\dagger \). By Sylvester’s Inertia Law
\[
n_\pm(CAB^\dagger C^\dagger) = n_\pm(AB^\dagger), \quad n_0(CAB^\dagger C^\dagger) = n_0(AB^\dagger)
\]
for any invertible \( C : \mathcal{K} \rightarrow \mathcal{K} \). Since for any such \( C \)
\[
\mathcal{M}(CA, CB) = \mathcal{M}(A, B),
\]
we may define
\[
n_\pm(\mathcal{M}) := n_\pm(AB^\dagger), \quad n_0(\mathcal{M}) := n_0(AB^\dagger)
\]
for arbitrary boundary conditions \( (A, B) \) satisfying \( \mathcal{M}(A, B) = \mathcal{M} \).

We mention several properties of numbers \( n_\pm(\mathcal{M}) \) and \( n_0(\mathcal{M}) \). First, by (2.10),
\[
n_\pm(\mathcal{M}_+) = n_\pm(\mathcal{M}), \quad n_0(\mathcal{M}_+) = n_0(\mathcal{M}).
\]
(3.10)
Second, for any unitary transformation \( U \) in \( \mathcal{K} \) one has
\[
n_\pm(U^\dagger \mathcal{M} U) = n_\pm(\mathcal{M}), \quad n_0(U^\dagger \mathcal{M} U) = n_0(\mathcal{M}),
\]
(3.11)
where \( U^\dagger \) denotes the “double” of \( U \),
\[
U^\dagger = \begin{pmatrix} U & 0 \\ 0 & U \end{pmatrix}.
\]
(3.12)
Finally, we have the following obvious inequality
\[
n_0(\mathcal{M}(A, B)) \geq \max\{\dim \ker A, \dim \ker B\}.
\]
(3.13)
The numbers \( n_\pm(M) \) and \( n_0(M) \) admit the following equivalent characterization in terms of the matrices \( \Sigma(k;M) \).

**Proposition 3.4.** Let \( M \subset dK \) be maximal isotropic. For any \( k > 0 \) the number of eigenvalues of \( \Sigma(k;M) \) lying in the open upper (lower, respectively) complex half-plane is equal to \( n_+(M) \) (\( n-(M) \), respectively). The number of real eigenvalues of \( \Sigma(k;M) \) is equal to \( n_0(M) \).

**Proof.** Consider

\[
A_\Sigma = -\frac{1}{2} (\Sigma - I), \quad B_\Sigma = \frac{1}{2ik} (\Sigma + I)
\]

with \( \Sigma = \Sigma(k;M) \). Note that \( \Sigma(k;M) = \Sigma(k;A_\Sigma,B_\Sigma) \). Observing that

\[
A_\Sigma B_\Sigma^\dagger = \frac{1}{2k} \text{Im} \ \Sigma \equiv \frac{1}{4ik} (\Sigma - \Sigma^\dagger),
\]

we obtain that

\[
n_\pm(\text{Im} \ \Sigma(k;M)) = n_\pm(M), \quad n_0(\text{Im} \ \Sigma(k;M)) = n_0(M)
\]

for any \( k > 0 \). \( \square \)

Let \( M \subset dK \) be a maximal isotropic subspace. For arbitrary \( \varphi, \psi \in \text{Dom} \Delta(M,q) \) integrating by parts we obtain

\[
\langle \varphi, -\Delta(M,q)\psi \rangle_H = \sum_{j \in E \cup I} \langle \varphi', \psi' \rangle_{H_j} + \langle [\varphi], Q[\psi] \rangle_{dK},
\]

where \( Q = \begin{pmatrix} 0 & I \\ 0 & 0 \end{pmatrix} \) with respect to the orthogonal decomposition \( dK = K \oplus K \).

Using (2.11) it is an elementary exercise to check that the orthogonal projection in \( dK \) onto the subspace \( M \) is given by

\[
P_M = \begin{pmatrix} -B^\dagger & (AA^\dagger + BB^\dagger)^{-1}(-B,A) \\ -A^\dagger & (AA^\dagger + BB^\dagger)^{-1}B \end{pmatrix}
\]

(3.16)

where the block matrix notation is used with respect to the orthogonal decomposition \( dK = K \oplus K \). Since \([\varphi]\) and \([\psi]\) in (3.15) belong to \( M \), we obtain

\[
\langle [\varphi], Q[\psi] \rangle_{dK} = \langle [\varphi], Q_M[\psi] \rangle_{dK},
\]

where \( Q_M := P_M Q P_M \). Using (3.16) we get that

\[
Q_M = -\begin{pmatrix} -B^\dagger & (AA^\dagger + BB^\dagger)^{-1} AB^\dagger(AA^\dagger + BB^\dagger)^{-1}(-B,A).
\]

(3.17)

Thus, we have proven the following result.

**Proposition 3.5.** For any maximal isotropic subspace \( M \subset dK \)

\[
\langle \varphi, -\Delta(M,q)\psi \rangle_H = \sum_{j \in E \cup I} \langle \varphi', \psi' \rangle_{H_j} + \langle [\varphi], Q_M[\psi] \rangle_{dK},
\]

(3.18)

holds for all \( \varphi, \psi \in \text{Dom} \Delta(M,q) \).
Remark 3.6. Observe that $Q_M$ depends on the maximal isotropic subspace $\mathcal{M}$ only and not on the particular choice of the matrices $A$ and $B$ parametrizing $\mathcal{M}$. Thus, using the parametrization of the maximal isotropic subspace $\mathcal{M}$ by matrices $(\hat{A}, \hat{B})$ defined in (3.21) we obtain
\begin{equation}
Q_M = - \left( -P_{\text{Ker} B}^\perp \right) L (I + L^2)^{-2} \left( -P_{\text{Ker} B}^\perp, P_{\text{Ker} B} + L \right),
\end{equation}
where we have used the equality
\begin{equation}
\hat{A} \hat{B}^\dagger = L.
\end{equation}
Since $\text{Ker} L \supset \text{Ker} B$, the equality $\hat{A} \psi + \hat{B} \psi' = 0$ implies that $L^2 \psi + L \psi' = 0$. Therefore, for any $\psi \in \text{Dom}(\Delta(M, a))$ we obtain
\begin{equation}
\begin{split}
\left( -P_{\text{Ker} B}^\perp, P_{\text{Ker} B} + L \right) [\psi] &= -P_{\text{Ker} B}^\perp \psi + (P_{\text{Ker} B} + L) \psi' \\
&= -(I + L^2) P_{\text{Ker} B}^\perp \psi + P_{\text{Ker} B} \psi'.
\end{split}
\end{equation}
Hence,
\begin{equation}
L (I + L^2)^{-2} \left( -P_{\text{Ker} B}^\perp, P_{\text{Ker} B} + L \right) [\psi] = -(I + L^2)^{-1} L \psi.
\end{equation}
Therefore, using (3.19) we obtain that
\begin{equation}
\langle \varphi, Q_M [\psi] \rangle_{\mathcal{K}} = \langle \varphi, \tilde{Q}_M [\psi] \rangle_{\mathcal{K}},
\end{equation}
holds for all $\varphi, \psi \in \text{Dom}(\Delta(M, a))$, where
\begin{equation}
\tilde{Q}_M = \left( \begin{array}{cc} -L & 0 \\ 0 & 0 \end{array} \right)
\end{equation}
with the block-matrix notation with respect to the orthogonal decomposition $dK = K \oplus K$. Together with (3.15) this leads to the representation for the sesquilinear form of the operator $-\Delta(M, a)$ obtained previously by Kuchment in [13] Theorem 9.

From (3.17) it follows that $n_\pm(Q_M) = n_\pm(M)$. Thus, by Sylvester’s Inertia Law, Proposition 3.5 immediately implies that $-\Delta(M, a) \geq 0$ in the sense of quadratic forms, if the maximal isotropic subspace $\mathcal{M} \subset dK$ satisfies the condition $n_+(M) = 0$.

Using variational arguments, we prove a more general result:

Theorem 3.7. The number of negative eigenvalues of $-\Delta(M, a)$ counting their multiplicities is not bigger than $n_+(M)$. If $\mathcal{I} = \emptyset$, then $-\Delta(M)$ has precisely $n_+(M)$ negative eigenvalues.

For the proof we need the following simple lemma.

Lemma 3.8. Assume that $(A, B)$ satisfies (2.9). The function $f(\alpha) := \det(A - \alpha B)$ has precisely $n_+(M(A, B))$ positive zeroes and $n_-(M(A, B))$ negative zeroes (counting multiplicity). If $\alpha = 0$ is a zero of $f$, then its multiplicity equals $\text{Rank} B - n_+(M(A, B)) - n_-(M(A, B)) \leq n_0(M)$.

Proof. By Lemma 2.5 the boundary conditions $(A, B)$ are equivalent to the boundary conditions $(\hat{A}, \hat{B})$ defined in (2.21). Now assume that $\alpha > 0$ is a zero of $f$ with multiplicity $m \geq 1$. By (3.20), we have
\begin{equation}
\det(A - \alpha B) = c \det(\hat{A} - \alpha \hat{B}) = c \det(L - \alpha)
\end{equation}
with a nonzero constant $c \in \mathbb{C}$. Thus, $\alpha$ is an eigenvalue of $L$ with multiplicity $m$. By (3.20) it is also an eigenvalue of $AB^\dagger$.

The case of negative eigenvalues can be considered in exactly the same way.
Observe that by (3.21) the total number of zeroes of \( f(\varphi) \) equals the dimension of \( \text{Ran} B^\dagger \), that is, the rank of \( B \). Thus, \( \varphi = 0 \) is a zero of \( f(\varphi) \) with multiplicity

\[
\text{Rank } B - n_+ (\mathcal{M}(A, B)) - n_- (\mathcal{M}(A, B)) \leq |E| + 2|I| - n_+ (\mathcal{M}(A, B)) - n_- (\mathcal{M}(A, B)) = n_0 (\mathcal{M}(A, B)).
\]

\[
\square
\]

**Proof of Theorem 3.7** Set for brevity \( m = n_+ (\mathcal{M}) \). Assume that \(-\Delta (\mathcal{M}, \omega)\) has at least \( m + 1 \) negative eigenvalues. By the Min-Max Principle the \((m + 1)\)-st eigenvalue is given by

\[
\lambda_{m+1} = \sup_{N \subset \mathcal{H}} \inf_{\dim N = m} \sup_{\psi \in \text{Dom}(–\Delta (\mathcal{M}, \omega))} \inf_{\|\psi\|_\mathcal{H} = 1} \langle \psi, –\Delta (\mathcal{M}, \omega) \psi \rangle_\mathcal{H}.
\]

In particular, this implies that

\[
(3.22) \quad \lambda_{m+1} \geq \inf_{\psi \in \text{Dom}(–\Delta (\mathcal{M}, \omega))} \inf_{\|\psi\|_\mathcal{H} = 1} \sup_{\psi \perp N} \langle \psi, –\Delta (\mathcal{M}, \omega) \psi \rangle_\mathcal{H}
\]

for any \( m \)-dimensional subspace \( N \) of \( \mathcal{H} \).

Let \( \tilde{N}_m \subset \mathcal{H} \) be the subspace spanned by all eigenvectors of \( Q_M \) with negative eigenvalues. Since \( \text{Ker } \mathcal{Q}_M \supset \mathcal{M}^\perp \) the inclusion \( \tilde{N}_m \subset \mathcal{M} \) holds. We claim that there is an \( m \)-dimensional subspace \( \mathcal{N}_m \subset \mathcal{H} \) such that \( [\psi] \in \tilde{N}_m \) for any \( \psi \in \mathcal{N}_m \). Indeed, choose an arbitrary basis \( \chi^{(1)}, \ldots, \chi^{(m)} \) in \( \tilde{N}_m \). For every \( k \in \{1, \ldots, m\} \) solve the equation

\[
(–\Delta (\mathcal{M}, \omega) – 1) \psi^{(k)} = 0 \quad \text{with} \quad [\psi^{(k)}] = \chi^{(k)}.
\]

Let \( \theta : [0, \infty) \to [0, 1] \) be an arbitrary infinitely differentiable function with \( \theta(x) = 1 \) for all \( x \in [0, 1] \) and \( \theta(x) = 0 \) for all \( x \in [2, \infty) \). Now set \( \varphi_i^n(x) = \psi^{(k)} (x) \) for all \( i \in I \) and

\[
\varphi_i^n (x) = \varphi_i^n (x) \theta (x)
\]

for all \( e \in \mathcal{E} \). Obviously, \( [\varphi_i^n] = [\psi^{(k)}] \) and \( \varphi_i^n \in \text{Dom}(–\Delta (\mathcal{M}, \omega)) \). Since \( \psi^{(k)} \) are linearly independent, we can choose \( \mathcal{N}_m \) as a subspace in \( \mathcal{H} \) spanned by \( \psi^{(1)}, \ldots, \psi^{(m)} \).

Now setting \( \mathcal{N} = \mathcal{N}_m \) in (3.22) and using (3.15) we obtain that \( \lambda_{m+1} \geq 0 \), which is a contradiction.

The second statement of the theorem follows immediately from Lemma 3.8 \( \square \)

### 3.2. Eigenvalue zero

Obviously, if \( \Delta (\mathcal{M}, \omega) \psi = 0 \), then \( \psi \) has to be piecewise linear,

\[
(3.23) \quad \psi_i (x_i) = \alpha_i + \beta_i x_i, \quad i \in I \quad \text{and} \quad \psi_e (x_e) \equiv 0, \quad e \in \mathcal{E}.
\]

**Proposition 3.9** If \( n_+ (\mathcal{M}) = 0 \), then \( \dim \text{Ker } \Delta (\mathcal{M}, \omega) \leq n_0 (\mathcal{M}) \).

**Proof.** Since \( n_+ (\mathcal{M}) = 0 \), from (3.17) it follows that \( Q_M \geq 0 \). Therefore, if \( \psi \in \text{Ker } \Delta (\mathcal{M}, \omega) \), then by Proposition 3.5 we have \( \psi = 0 \). Hence, \( \psi \in \text{Ker } A \). Therefore, by (3.23),

\[
\dim \text{Ker } \Delta (\mathcal{M}, \omega) \leq \dim \text{Ker } A.
\]

By (3.13) the dimension of \( \text{Ker } A \) does not exceed \( n_0 (\mathcal{M}) \), which proves the claim. \( \square \)

Solutions of the Laplace equation on infinite periodic metric graphs have been studied recently by Kuchment and Pinchover in [14]. The kernel of the Laplace operator \( –\Delta (\mathcal{M}, \omega) \) on compact graphs with standard boundary conditions has been studied by Kurasov and Novaszk in [15].
3.3. **Lower bounds on the spectrum.** Corollary 10 in [13] in a slightly generalized form provides the following lower bound

\[ -\Delta(M, a) \geq -4\|L_+\|(|E| + 2|I|) \max \{2\|L_+\|, \max_{i \in I} a_i - 1\}, \]

where \( L_+ \) is the positive part of the self-adjoint operator \( L = (B|_{\text{Ran}B})^{-1} AP(\ker B)^\perp \) defined in Lemma 2.5. Observe that the r.h.s. of this estimate depends linearly on the total degree of the graph \( G \), that is, on the number \( \sum_{v \in V} \deg(v) = |E| + 2|I| \). The following theorem provides a lower bound on the spectrum of Laplace operator, which is uniform with respect to this quantity.

**Theorem 3.10.** Assume that \( I \neq \emptyset \). Then

\[ -\Delta(M, a) \geq -s(\|L_+\|^2), \]

where \( s(t) \) is the unique nonnegative solution of the equation

\[ s \tanh \left( \frac{as}{2} \right) = t, \quad a = \min_{i \in I} a_i. \]

Obviously, \( s(0) = 0 \), \( s(t) \) is increasing in \( t \) and satisfies the estimate \( s(t) \geq t \) for all \( t \geq 0 \).

**Remark 3.11.** Assume that \( I = \emptyset \) and \( n_+(M) > 0 \). Then by Theorem 3.2 and Lemma 2.5 the number \( \lambda = -\|L_+\|^2 \) is the smallest eigenvalue of \( -\Delta(M) \).

**Proof of Theorem 3.10.** If \( L_+ = 0 \) the claim follows from Theorem 3.7 by (3.20). Thus, we may assume that \( L_+ \neq 0 \). For brevity we set \( \kappa_0 := \|L_+\| \). Observe that by (3.21), the number \( \kappa_0 \) is the biggest positive solution of the equation \( \det(A - \kappa B) = 0 \).

For arbitrary \( \kappa > \kappa_0 \) by (3.22) we have

\[ \|S(i\kappa; A, B)\| = \frac{\kappa + \kappa_0}{\kappa - \kappa_0} > 1. \]

By Theorem 3.2 if \( -\kappa_1^2 < 0 \) is an eigenvalue of \( -\Delta(M(A, B), a) \), then either

\[ \det(A - \kappa_1 B) = 0 \]

or

\[ \det[I - S(i\kappa_1; A, B)T(i\kappa_1; a)] = 0 \]

holds. In the first case \( \kappa_1 = \kappa_0 \). If the second case holds, then necessarily

\[ \|S(i\kappa_1; A, B)T(i\kappa_1; a)\| \geq 1, \]

and, therefore,

\[ \|S(i\kappa_1; A, B)\| \|T(i\kappa_1; a)\| \geq 1. \]

Therefore,

\[ \kappa_1 \leq \kappa_2 := \inf\{\kappa > 0 | \|S(i\kappa; A, B)\| \|T(i\kappa; a)\| < 1\}. \]

From (3.25) it follows that

\[ \|S(i\kappa; A, B)\| \|T(i\kappa; a)\| \leq \frac{\kappa + \kappa_0}{\kappa - \kappa_0} e^{-a\kappa} \]

for all \( \kappa > \kappa_0 \). Therefore, \( \kappa_2 \) is not bigger then the unique positive solution of the equation

\[ \frac{\kappa + \kappa_0}{\kappa - \kappa_0} e^{-a\kappa} = 1. \]

It is straightforward to verify that this solution is given by \( s(\kappa_0) \) and \( s(\kappa_0) \geq \kappa_0 \). \( \square \)
4. The Resolvent

In this section we will study the resolvent of the Laplace operator on a metric graph \((G, \omega)\). In particular, we show that the resolvent is an integral operator. The structure of the underlying Hilbert space \(H \subseteq L^2\) naturally gives rise to the following definition of integral operators.

**Definition 4.1.** The operator \(K\) on the Hilbert space \(H\) is called integral operator if for all \(j, j' \in \mathcal{E} \cup \mathcal{I}\) there are measurable functions \(K_{j,j'}(\cdot, \cdot) : I_j \times I_{j'} \to \mathbb{C}\) with the following properties

\[
\begin{align*}
(i) & \quad K_{j,j'}(x, \cdot) \in L^1(I_{j'}) \text{ for almost all } x_j \in I_j, \\
(ii) & \quad \psi = K\psi \text{ with }
\end{align*}
\]

\[
(4.1) \quad \psi_j(x_j) = \sum_{j' \in \mathcal{E} \cup \mathcal{I}} \int_{I_{j'}} K_{j,j'}(x_j, y_{j'}) \psi_{j'}(y_{j'}) dy_{j'}.
\]

The \((|\mathcal{I}| + |\mathcal{E}|) \times (|\mathcal{I}| + |\mathcal{E}|)\) matrix-valued function \((x, y) \mapsto K(x, y)\) with

\[
[K(x, y)]_{j,j'} = K_{j,j'}(x_j, y_{j'})
\]

is called the integral kernel of the operator \(K\).

Below we will use the following shorthand notation for \((4.1)\):

\[
\psi(x) = \int_{\mathcal{E}} K(x, y) \varphi(y) dy.
\]

**Lemma 4.2.** For any maximal isotropic subspace \(M \subset dK\) the resolvent

\[
(-\Delta(M; \omega) - k^2)^{-1} \quad \text{for} \quad k^2 \in \mathbb{C} \setminus \text{spec}(-\Delta(M; \omega))
\]

is the integral operator with the \((|\mathcal{I}| + |\mathcal{E}|) \times (|\mathcal{I}| + |\mathcal{E}|)\) matrix-valued integral kernel \(r_M(x, y; k, \omega)\). If \(k > 0\), admitting the representation

\[
r_M(x, y; k, \omega) = r^{(0)}(x, y; k, k)
\]

\[
- \frac{i}{2k} \Phi(x, k) Z(k; A, B, \omega)^{-1} (A - ikB) R_+ (k; \omega)^{-1} \Phi(y, k)^T,
\]

where \(Z(k; A, B, \omega)\) is defined in \((3.3)\), the matrix \(\Phi(x, k)\) is given by

\[
\Phi(x, k) := \begin{pmatrix}
\phi(x, k) & 0 & 0 \\
0 & \phi_+(x, k) & 0 \\
0 & 0 & \phi_-(x, k)
\end{pmatrix}
\]

with diagonal matrices \(\phi(x, k) = \text{diag}\{e^{ikx_j}\}_{j \in \mathcal{E}}, \phi_\pm(x, k) = \text{diag}\{e^{\pm ikx_j}\}_{j \in \mathcal{I}}\), and

\[
[r^{(0)}(x, y; k)]_{j,j'} = \frac{i\delta_{j,j'} e^{ik|x_j - y_j|}}{2k}, \quad x_j, y_j \in I_j.
\]

If \(\det(A + ikB) \neq 0\), then

\[
r_M(x, y; k, \omega) = r^{(0)}(x, y; k, k)
\]

\[
+ \frac{i}{2k} \Phi(x, k) R_+(k; \omega)^{-1} [1 - \mathcal{G}(k; M) T(k; \omega)]^{-1} \mathcal{G}(k; M) R_+(k; \omega)^{-1} \Phi(y, k)^T,
\]

where \(R_+(k; \omega)\) is defined in \((3.8)\). If \(\mathcal{I} = \emptyset\), this representation simplifies to

\[
r_M(x, y; k) = r^{(0)}(x, y; k) + \frac{i}{2k} \phi(x, k) \mathcal{G}(k; M) \phi(y, k).
\]
The integral kernel $r_M(x, y; k, \varrho)$ is called Green’s function or Green’s matrix.

An alternative representation for Green’s function of the Laplace operator on a graph with $\mathcal{I} = \emptyset$ has been given in [3].

**Proof.** Since $k^2$ is not an eigenvalue of $-\Delta(M; \varrho)$, by Lemma 3.1, the inverse in (4.1) exists. Define the operator $M(k)$ as the integral operator with kernel (4.2).

Let $\varphi \in \mathcal{H}$ be arbitrary. Set $\psi = M(k)\varphi$. Obviously, $\psi(x)$ is bounded and $\psi \in \mathcal{H}$. To prove that $(-\Delta(M; \varrho) - k^2)^{-1} = M(k)$, it suffices to show that

(i) $\psi \in \text{Dom}(\Delta(M; \varrho))$,
(ii) $(-\Delta(M; \varrho) - k^2)\psi = \varphi$,
(iii) the symmetry relation

$$r_M(y, x; k, \varrho) = r_M(x, y; -k, \varrho)^\dagger$$

holds.

**Proof of (i).** Obviously, $\psi \in \mathcal{D}$, where $\mathcal{D} = \bigoplus_{j \in \mathcal{E} \cup \mathcal{I}} \mathcal{D}_j$ and $\mathcal{D}_j$ denotes the set of all $f_j \in \mathcal{H}_j$ such that $f_j(x_j)$ and its derivative $f'_j(x_j)$ are absolutely continuous and $f''_j(x_j)$ is square integrable. Set for brevity

$$G(k) := -Z(k; A, B, \varrho)^{-1}(A - ikB)R_+(k; \varrho)^{-1}.$$

Assume that $\varphi_j \in \mathcal{H}_j$ vanishes in a neighborhood of $x_j = 0$ and, in addition, in a neighborhood of $x_j = a_j$ if $j \in \mathcal{I}$. Then

$$\int_{I_j} e^{ik|x_j - y_j|}\varphi_j(y_j)dy_j = \int_{I_j} e^{-ik|x_j - y_j|}\varphi_j(y_j)dy_j$$

holds for all sufficiently small $x_j \in I_j$ and

$$\int_{I_j} e^{ik|x_j - y_j|}\varphi_j(y_j)dy_j = \int_{I_j} e^{ik|x_j - y_j|}\varphi_j(y_j)dy_j$$

holds for all $x_j \in I_j$ sufficiently close to $a_j$ if $j \in \mathcal{I}$. A simple calculation leads to

$$\psi = \frac{1}{2k} R_+(k; \varrho)^{-1} \int_{\mathcal{G}} \Phi(y, k)^T \varphi(y)dy + \frac{1}{2k} X(k; \varrho)G(k) \int_{\mathcal{G}} \Phi(y, k)^T \varphi(y)dy$$

and

$$\psi' = \frac{1}{2} R_+(k; \varrho)^{-1} \int_{\mathcal{G}} \Phi(y, k)^T \varphi(y)dy - \frac{1}{2} Y(k; \varrho)G(k) \int_{\mathcal{G}} \Phi(y, k)^T \varphi(y)dy,$$

where $\psi$ and $\psi'$ are defined by [4.3]. Therefore,

$$A\psi + B\psi' = \frac{1}{2k} (A - ikB)R_+(k; \varrho)^{-1} \int_{\mathcal{G}} \Phi(y, k)^T \varphi(y)dy$$

$$+ \frac{1}{2k} Z(k; A, B, \varrho)G(k) \int_{\mathcal{G}} \Phi(y, k)^T \varphi(y)dy = 0.$$ 

Thus, we proved that $A\psi + B\psi' = 0$ for all $\varphi$ in a dense subset of $\mathcal{H}$. Therefore, $A\psi + B\psi' = 0$ for all $\varphi \in \mathcal{H}$, which proves the claim (i).

**Proof of (ii).** Assume that $\varphi_j \in \mathcal{H}_j$ is continuous on $I_j$ for every $j \in \mathcal{I} \cup \mathcal{E}$. Standard arguments based on the Fourier transform show that

$$-\frac{i}{2k} \left( \frac{d^2}{dx_j^2} + k^2 \right) \int_{I_j} e^{ik|x_j - y_j|}\varphi_j(y_j)dy_j = \varphi_j(x_j), \quad x_j \in \bar{I}_j, \quad j \in \mathcal{E} \cup \mathcal{I}.$$
where \( I^\circ_j \) denotes the interior of \( I_j \). This implies that

\[
-\frac{i}{2k} \left( \frac{d^2}{dx_j^2} + k^2 \right) \psi_j(x_j) = \varphi_j(x_j)
\]

for all \( x_j \in I^\circ_j \). Hence, \( (-\Delta(M; \mathbf{a}) - k^2) \psi = \varphi \) for all \( \varphi \) in a dense subset of \( \mathcal{H} \). Since \( M(k) \) is bounded, the claim follows.

**Proof of (iii).** It suffices to prove (4.4) for the representation (4.3). For the representation (4.2) the symmetry relation (4.4) will follow by continuity from (4.5).

The relation \( r^{(0)}(y, x, k) = r^{(0)}(x, y, -k) \) is obvious. Observe that \( R_+(k; \mathbf{u})\dagger = R_+(\mathbf{-u}) \). Similarly,

\[
T(k; \mathbf{u}) = T(\mathbf{-u}) \quad \text{and} \quad \Phi(x, k)\dagger = \Phi(x, -k)^T \quad \text{(transpose)}.
\]

The proof of the identity

\[
\mathcal{S}(k; M)[I - T(k; \mathbf{u})\mathcal{S}(k; M)]^{-1} = [I - \mathcal{S}(k; M)T(k; \mathbf{u})]^{-1}\mathcal{S}(k; M).
\]

is elementary and left to the reader. Now combining these relations we obtain

\[
r_M(x, y, -\mathbf{u}) = r^{(0)}(y, x, k) + \frac{i}{2k}\Phi(y, k)R_+(k; \mathbf{u})^{-1}[I - \mathcal{S}(-\mathbf{u}; M)^\dagger T(k; \mathbf{u})]^{-1}\mathcal{S}(-\mathbf{u}; M)^\dagger R_+(k; \mathbf{u})^{-1}\Phi(x, k)^T.
\]

Using the symmetry property

\[
\mathcal{S}(\mathbf{-u}; M) = \mathcal{S}(k; M),
\]

we obtain relation (4.4).

**Proof of (4.5).** Recall that if \( \det(A + ikB) \neq 0 \), then

\[
\mathcal{S}(k; A, B, \mathbf{u}) = (A + ikB)[I - \mathcal{S}(k; A, B)T(k; \mathbf{u})]R_+(k; \mathbf{u}).
\]

Thus, (4.5) follows from (4.2). \( \square \)

Observe that by Corollary 2.6 for any maximal isotropic subspace \( M \subset \mathcal{K} \) the operator \( \mathcal{S}(ix; M) \) is self-adjoint for all \( x > 0 \). Moreover, \( \mathcal{S}(ix; M) \) is real if and only if the matrices \( (A, B) \) defining \( M \) via (2.3) can be chosen real. Indeed, by (2.22), the matrix \( \mathcal{S}(ix; M) \) is real if and only if \( L \) is.

If \( n_+(M) = 0 \), then again by Corollary 2.6 \( \mathcal{S}(ix; M) \) is a self-adjoint contraction for all \( x > 0 \). Therefore, \( I + \mathcal{S}(ix; M) \) is a nonnegative operator whenever \( x > 0 \).

**Definition 4.3.** For any square matrix \( C \) write \( C \geq 0 \) (respectively, \( C > 0 \)) if all entries of the matrix \( C \) are nonnegative (respectively, positive). We write \( C_1 \succeq C_2 \) (respectively, \( C_1 > C_2 \)) if \( C_1 - C_2 \succeq 0 \) (respectively, \( C_1 - C_2 > 0 \)).

**Definition 4.4.** The maximal isotropic subspace \( M \subset \mathcal{K} \) is called positive, if there is a \( x_0 \geq 0 \) such that \( I + \mathcal{S}(ix; M) \succeq 0 \) for all \( x \geq x_0 \). It is called strictly positive, if \( I + \mathcal{S}(ix; M) > 0 \) for all \( x \geq x_0 \). It is called locally strictly positive, if the boundary conditions defined by \( M \) are local in the sense of Definition 2.3 and \( I + \mathcal{S}(ix; M; v) \succeq 0 \) for all \( x \geq x_0 \) and all \( v \in V \). Here \( M(v) \) denotes the maximal isotropic subspace from the orthogonal decomposition (2.13).

Obviously, strictly positive maximal isotropic subspaces are positive. If \( M \) defines local boundary conditions on the graph \( \mathcal{G} \), then there are permutation matrices \( \Pi \in U(|E| + 2|I|) \) such that \( \Pi \mathcal{S}(ix; M) \Pi^{-1} \) is block-diagonal with blocks \( \{\mathcal{S}(ix; M(v))\}_{v \in V} \) (see...
discussion in [12]). Therefore, since every element of the matrix $I$ is either 1 or 0, if $M$ is locally strictly positive, then $M$ is positive but not strictly positive.

**Example 4.5.** Consider the standard boundary conditions defined in Example 2.4. From (2.20) it follows that
\[
[I + \mathcal{S}(k; M(v))]_{e,e'} = \frac{2}{\deg(v)} > 0
\]
for all $e, e' \in E_v$. Thus, the standard boundary conditions are strictly positive on any graph $G$, and locally strictly positive on the graph $\mathcal{G}$.

**Theorem 4.6.** Assume that the maximal isotropic subspace $M$ is strictly positive. Then the Green function $r_M(x, y; i \kappa, \mathcal{G}) > 0$ for all sufficiently large $\kappa \geq 0$. Moreover, if the graph has no internal lines ($I = \emptyset$), then $r_M(x, y; i \kappa, \mathcal{G}) \geq 0$ for all sufficiently large $\kappa \geq 0$ whenever the maximal isotropic subspace $M$ is positive.

The case of locally strictly positive maximal isotropic subspaces will be treated in the following section.

For the proof of Theorem 4.6 we need the following lemma.

**Lemma 4.7.** Assume that $I \neq \emptyset$. If the maximal isotropic subspace $M = M(A, B)$ is strictly positive, then
\[
(I + [I - \mathcal{S}(i \kappa; M)T(i \kappa; \mathcal{G})]^{-1}\mathcal{S}(i \kappa; M)) > 0
\]
holds for all sufficiently large $\kappa \geq 0$.

**Proof.** Let $\kappa_0 > 0$ be the largest solution of the equation $\det(A - \kappa B) = 0$. By Proposition 3.11 in [12] there are positive numbers $\kappa_1 \geq \kappa_0$ and $C > 0$ such that
\[
\|\mathcal{S}(i \kappa; M)\| \leq C
\]
holds for all $\kappa \geq \kappa_1$. Observing that $\|T(i \kappa; \mathcal{G})\| \leq e^{-\alpha \kappa}$ with $\alpha := \min a_j$ for all $\kappa > 0$, we obtain that $\|\mathcal{S}(i \kappa; M)T(i \kappa; \mathcal{G})\| < 1/2$ for all $\kappa > \kappa_2 := \max\{\kappa_1, -\alpha^{-1}\log(2C)\}$. Therefore,
\[
(I + [I - \mathcal{S}(i \kappa; M)T(i \kappa; \mathcal{G})]^{-1}\mathcal{S}(i \kappa; M))
\]
converges absolutely for all $\kappa > \kappa_2$. Furthermore, for all $\kappa > \kappa_2$ the estimate
\[
\left\|\sum_{n=1}^{\infty}[\mathcal{S}(i \kappa; M)T(i \kappa; \mathcal{G})]^{n}\mathcal{S}(i \kappa; M)\right\|
\]
\[
\leq \sum_{n=1}^{\infty}\|\mathcal{S}(i \kappa; M)\|^{n+1}\|T(i \kappa; \mathcal{G})\|^n
\]
\[
\leq \frac{\|\mathcal{S}(i \kappa; M)\|^2\|T(i \kappa; \mathcal{G})\|}{1 - \|\mathcal{S}(i \kappa; M)T(i \kappa; \mathcal{G})\|} \leq 2C^2e^{-\alpha \kappa}
\]
holds. Since all matrix elements of $I + \mathcal{S}(i \kappa; M)$ are rational functions in $\kappa$, which are positive for sufficiently large $\kappa$, we obtain the claim. \qed
Proof of Theorem 4.6. We start with the case $I = \emptyset$. If $e \neq e'$, then
\[
[r_M(x, y; i\kappa)]_{e,e'} = \frac{1}{2\kappa} e^{-\kappa x e} \mathcal{S}(i\kappa; M)]_{e,e'} e^{-\kappa y e'} \geq 0
\]
for all $x_e \in I_e$ and $y_{e'} \in I_{e'}$. Now consider the case $e = e'$. Noting the inequality
\[
e^{-\kappa x e - y_e} \geq e^{-\kappa x e} e^{-\kappa y e}
\]
we obtain that
\[
[r_M(x, y; i\kappa)]_{e,e} \geq \frac{1}{2\kappa} e^{-\kappa x e} e^{-\kappa y e} + \frac{1}{2\kappa} e^{-\kappa x e} \mathcal{S}(i\kappa; M)]_{e,e} e^{-\kappa y e}
\]
holds for all sufficiently large $\kappa$ by the assumption $I + S(i\kappa; M) \succ 0$.

Using Lemma 4.7 the case $I \neq \emptyset$ can be treated in the same way. \qed

5. Local Boundary Conditions: Positivity of Green’s Function

In this section we will prove an extension of Theorem 4.6 to the case of locally strictly positive maximal isotropic subspaces.

Theorem 5.1. Assume that $I \neq \emptyset$ and the graph $\mathcal{G}$ has no tadpoles. If the maximal isotropic subspace $M$ is locally strictly positive, then the Green function satisfies $r_M(x, y; i\kappa, \mathcal{G}) \succ 0$ for all sufficiently large $\kappa \geq 0$.

The proof of this theorem is more involved than that of Theorem 4.6. Unlike the case of (globally) positive maximal isotropic subspaces, for locally strictly positive maximal isotropic subspace the inequality
\[
I + [I - \mathcal{S}(i\kappa; M)T(i\kappa; \mathcal{G})]^{-1}\mathcal{S}(i\kappa; M) \succ 0
\]
in general need not hold for all large $\kappa > 0$.

Before we turn to the proof of Theorem 5.1 we introduce some notion and auxiliary results.

5.1. Walks on Graphs. A nontrivial walk $w$ on the graph $\mathcal{G}$ from $j \in \mathcal{E} \cup \mathcal{I}$ to $j' \in \mathcal{E} \cup \mathcal{I}$ is a sequence
\[(5.1) \quad \{j, v_0, j_1, v_1, \ldots, j_n, v_n, j'\}\]
such that
(i) $j_1, \ldots, j_n \in \mathcal{I}$;
(ii) the vertices $v_0 \in V$ and $v_n \in V$ satisfy $v_0 \in \partial(j), v_0 \in \partial(j_1), v_n \in \partial(j')$, and $v_n \in \partial(j_n)$;
(iii) for any $k \in \{1, \ldots, n - 1\}$ the vertex $v_k \in V$ satisfies $v_k \in \partial(j_k)$ and $v_k \in \partial(j_{k+1})$;
(iv) $v_k = v_{k+1}$ for some $k \in \{0, \ldots, n - 1\}$ if and only if $j_k$ is a tadpole.

If $j, j' \in \mathcal{E}$ this definition is equivalent to that given in [12].

The number $n$ is the combinatorial length $|w|_{\text{comb}}$ and the number
\[
|w| = \sum_{k=1}^{n} a_{j_k} > 0
\]
is the metric length of the walk $w$.

A trivial walk on the graph $\mathcal{G}$ from $j \in \mathcal{E} \cup \mathcal{I}$ to $j' \in \mathcal{E} \cup \mathcal{I}$ is a triple $\{j, v, j'\}$ such that $v \in \partial(j)$ and $v \in \partial(j')$. Otherwise the walk is called nontrivial. In particular, if
\( \partial(j) = \{v_0, v_1\} \), then \( \{j, v_0, j\} \) and \( \{j, v_1, j\} \) are trivial walks, whereas \( \{j, v_0, j, v_1, j\} \) and \( \{j, v_1, j, v_0, j\} \) are nontrivial walks of combinatorial length 1. Both the combinatorial and metric length of a trivial walk are zero.

We will say that the walk (5.1) leaves the edge \( j \) through the vertex \( v_0 \) and enters the edge \( j' \) through the vertex \( v_n \). A trivial walk \( \{j, v, j'\} \) leaves \( j \) and enters \( j' \) through the same vertex \( v \).

A walk \( \mathbf{w} = \{j, v_0, j_1, v_1, \ldots, j_n, v_n, j'\} \) traverses an internal edge \( i \in \mathcal{I} \) if \( j_k = i \) for some \( 1 \leq k \leq n \). It visits the vertex \( v \) if \( v_k = v \) for some \( 0 \leq k \leq n \). The score \( m(\mathbf{w}) \) of a walk \( \mathbf{w} \) is the set \( \{n_i(\mathbf{w})\}_{i \in \mathcal{I}} \) with \( n_i(\mathbf{w}) \geq 0 \) being the number of times the walk \( \mathbf{w} \) traverses the internal edge \( i \in \mathcal{I} \).

We say that the walk is transmitted at the vertex \( v_k \) if either \( v_k = \partial(e) \) or \( v_k = \partial(e') \) or \( v_k \in \partial(i_k) \), \( v_k \in \partial(i_{k+1}) \), and \( i_k \neq i_{k+1} \). We say that a trivial walk from \( e' \) to \( e \) is transmitted at the vertex \( v = \partial(e) = \partial(e') \) if \( e \neq e' \). Otherwise the walk is said to be reflected. The walk is said to be reflectionless if it is transmitted at any vertex visited by this walk.

Let \( \chi, \chi' \) be two arbitrary distinct elements of the canonical orthonormal basis in \( \mathcal{K} \), that is all components of \( \chi \) are zero with the exception of one which is equal to 1. Let \( \mathbf{v} \) be

\( \begin{align*}
(1) & \quad \text{the initial vertex of the internal edge } j \in \mathcal{I} \text{ if } \chi \in \mathcal{K}^\ell_\mathcal{I}(-), \\
(2) & \quad \text{the terminal vertex of the internal edge } j \in \mathcal{I} \text{ if } \chi \in \mathcal{K}^\ell_\mathcal{I}(+), \\
(3) & \quad \text{the initial vertex of the external edge } j \in \mathcal{E} \text{ if } \chi \in \mathcal{K}_\mathcal{E}.
\end{align*} \)

Assume that \( \mathbf{v}' \) is determined by the same rule from \( \chi' \).

Assume that the maximal isotropic subspace \( \mathcal{M} \subset \mathcal{K} \) defines local boundary conditions in the sense of Definition 2.3. It is straightforward to check that for any \( m \in \mathbb{N} \) the equality

\[ \langle \chi, \mathcal{S}(\mathbb{K}^\ell; \mathcal{M}) (\mathcal{T}(\mathbb{K}^\ell; \mathcal{M}))^m \rangle \chi' = \sum_{\text{all walks } \mathbf{w} \text{ of \combinatorial length } m \text{ from } j \text{ to } j'} e^{i[k] \mathbf{w}} W(k; \mathbf{w}) \]

holds, where the weight \( W(k; \mathbf{w}) \) associated with the walk \( \mathbf{w} = \{j, v, j_1, v_1, \ldots, v_{m-1}, j_m, v', j'\} \) is given by

\[ W(k; \mathbf{w}) := [\mathcal{S}(i\varepsilon; \mathcal{M}(v_1))]_{j,j_1} \cdot \left( \prod_{l=1}^{m-1} [\mathcal{S}(i\varepsilon; \mathcal{M}(v_l))]_{j_l,j_{l+1}} \right) [\mathcal{S}(i\varepsilon; \mathcal{M}(v'))]_{j_{m-1},j'}. \]

If \( m = 1 \) the product in the brackets has to be replaced by 1. For \( m = 0 \) and \( v = v' \) we have a similar representation

\[ \langle \chi, \mathcal{S}(\mathbb{K}; \mathcal{M}) \chi' \rangle = [\mathcal{S}(i\varepsilon; \mathcal{M}(v))]_{j,j'}, \]

which corresponds to the trivial walk \( \{j, v, j'\} \).

Let \( \mathcal{W}_{\mathbb{K}}(\sigma, \sigma') \), \( \sigma, \sigma' \in \{+, -\} \) denote the set of all walks from \( j \) to \( j' \) leaving \( j \) through \( \partial^\sigma(j) \) and entering \( j' \) through \( \partial^\sigma'(j') \). Observe that these sets are disjoint.
Lemma 4.2 and in particular equation (4.3) imply the following representation for Green’s matrix
\[
[r_M(x, y, i\kappa, \underline{a})]_{j,j'} = [\nu^{(0)}(x, y, i\kappa)]_{j,j'} + \frac{1}{2\kappa} \left( e^{-\kappa x_j} \sum_{w \in W^{-}_{j,j'}} W(i\kappa; w) e^{-\kappa|w|} e^{-\kappa x_{j'}} + e^{-\kappa(a_j - x_j)} \sum_{w \in W^{-}_{j,j'}} W(i\kappa; w) e^{-\kappa|w|} e^{-\kappa x_{j'}} \right.
\]
\[+ e^{-\kappa x_j} \sum_{w \in W^{+}_{j,j'}} W(i\kappa; w) e^{-\kappa|w|} e^{-\kappa x_{j'}} + e^{-\kappa(a_j - x_j)} \sum_{w \in W^{+}_{j,j'}} W(i\kappa; w) e^{-\kappa|w|} e^{-\kappa(a_j - y_{j'})} \right) ,
\]
(5.2)
which holds for all sufficiently large \( \kappa > 0 \).

5.2. Proof of Theorem 5.1 Below we will present a proof of Theorem 5.1 for the case \( j, j' \in I \). If one or both edges are external, the proof follows the same lines and actually is simpler than in the case considered below.

Case I: Assume that \( j = j' \). Set \( v := \partial^-(j) \). From (4.3) and (5.2) it follows that
\[
[r_M(x, y, i\kappa, \underline{a})]_{j,j} = e^{-2\kappa x_j} \left( 1 + [\mathcal{G}(i\kappa; A(v), B(v))]_{j,j} + O(e^{-2\kappa a_j}) \right)
\]
holds for sufficiently large \( \kappa > 0 \). Since \( M \) is locally strictly positive, we have
\[
[r_M(x, y, i\kappa, \underline{a})]_{j,j} > 0
\]
for all large \( \kappa > 0 \).

Case II: Assume now that \( j \neq j' \). For arbitrary \( \sigma \in \{-, +\} \) we will write
\[
\overline{\sigma} := \begin{cases} -, & \text{if } \sigma = +, \\ +, & \text{if } \sigma = -. \end{cases}
\]

Lemma 5.2. Assume that the graph \( \mathcal{G} \) has no tadpoles. Let \( w \in W^{(\sigma, \overline{\sigma})}_{j,j'} \) be a walk with the smallest metric length among all walks in \( W^{(\sigma, \overline{\sigma})}_{j,j'} \). Assume that \( w \) is not reflectionless.

Then there is a reflectionless walk \( w' \in W^{(\sigma, \overline{\sigma})}_{j,j'} \cup W^{(\overline{\sigma}, \sigma')}_{j,j'} \cup W^{(\overline{\sigma}, \overline{\sigma})}_{j,j'} \) from \( j \) to \( j' \) such that
\[
\begin{align*}
\text{if } w' \in W^{(\sigma, \overline{\sigma})}_{j,j'} & \quad w = \{ j, \partial^-(j), w' \}, \\
\text{if } w' \in W^{(\overline{\sigma}, \sigma')}_{j,j'} & \quad w = \{ w', \partial^+(j'), j' \}, \\
\text{if } w' \in W^{(\overline{\sigma}, \overline{\sigma})}_{j,j'} & \quad w = \{ j, \partial^+(j), w', \partial^-(j'), j' \}
\end{align*}
\]
(5.3)

Proof. Since \( w \in W^{(\sigma, \overline{\sigma})}_{j,j'} \) is a walk with the smallest metric length among all walks in \( W^{(\sigma, \overline{\sigma})}_{j,j'} \), it is reflected at least one of the vertices in \( \partial(j) \) and \( \partial(j') \). With this observation the claim is obvious.
Lemma 5.3. Assume that the walk \( w^{(\sigma, \sigma')} \in \mathcal{W}_{j,j'}^{(\sigma, \sigma')} \) is reflectionless. Set
\[
\begin{align*}
\sigma &= \{ j, \partial^+ (j), w^{(\sigma, \sigma')} \} \in \mathcal{W}_{j,j'}^{(\sigma, \sigma')}, \\
\sigma' &= \{ w^{(\sigma, \sigma')}, \partial^- (j'), \} \in \mathcal{W}_{j,j'}^{(\sigma, \sigma')}, \\
\sigma &= \{ j, \partial^+ (j), w^{(\sigma, \sigma')}, \partial^- (j'), \} \in \mathcal{W}_{j,j'}^{(\sigma, \sigma')},
\end{align*}
\]
Then
\[
F(x_j, y_j', \kappa) := e^{-\kappa x_j} W(i \kappa; w^{(-,-)}) e^{-\kappa|w^{(-,-)}| e^{-\kappa y_j'}}
\]
(5.4)
is positive for all sufficiently large \( \kappa > 0 \) and all \( x_j \in I_j, y_j' \in I_{j'} \).

Proof. There are four different cases according to each choice of \((\sigma, \sigma')\). It suffices to consider one case, since the other three cases may be discussed in the same way. We pick the case \((\sigma, \sigma') = (-,-)\), so the walk \( w^{(-,-)} \) is assumed to be reflectionless. By construction we have
\[
\begin{align*}
|w^{(+,-)}| &= |w^{(-,-)}| + a_j, \\
|w^{(-,+)}| &= |w^{(-,-)}| + a_{j'}, \\
|w^{(+,+)}| &= |w^{(-,-)}| + a_j + a_{j'}.
\end{align*}
\]
Set \( v := \partial^+ (j) \) and \( v' := \partial^+ (j') \). Obviously,
\[
\begin{align*}
W(i \kappa; w^{(+,-)}) &= W(i \kappa; w^{(-,-)})|\mathcal{S}(i \kappa; M(v))|_{j,j}, \\
W(i \kappa; w^{(-,+)}) &= W(i \kappa; w^{(-,-)})|\mathcal{S}(i \kappa; M(v'))|_{j',j'}, \\
W(i \kappa; w^{(+,+)}) &= W(i \kappa; w^{(-,-)})|\mathcal{S}(i \kappa; M(v))|_{j,j} |\mathcal{S}(i \kappa; M(v'))|_{j',j'}.
\end{align*}
\]
The inequalities
\[
[\mathcal{S}(i \kappa; M(v))]|_{j,j} > -1, \quad [\mathcal{S}(i \kappa; M(v'))]|_{j',j'} > -1
\]
hold for all large \( \kappa > 0 \) since \( M \) is locally strictly positive. Hence we may write
\[
F(x_j, y_j', \kappa) = e^{-\kappa x_j} W(i \kappa; w^{(-,-)}) e^{-\kappa|w^{(-,-)}| e^{-\kappa y_j'}} (1 + a(\kappa))(1 + b(\kappa))
\]
where
\[
-1 < a(\kappa) = e^{-2\kappa(a_j - x_j)} [\mathcal{S}(i \kappa; M(v))]|_{j,j}, \quad -1 < b(\kappa) = e^{-2\kappa(a_{j'} - y_j' )} [\mathcal{S}(i \kappa; M(v'))]|_{j',j'}
\]
holds for all large \( \kappa \). Now \( W(i \kappa; w^{(-,-)}) > 0 \) since \( w^{(-,-)} \) is reflectionless. Therefore
\( F(x_j, y_j', \kappa) \) is positive for all large \( \kappa > 0 \).

Now we are in the position to complete the proof of Theorem 5.1.

Assume that \( w \) is a shortest walk in \( \mathcal{W}_{j,j'}^{(\sigma, \sigma')} \) for some \( \sigma, \sigma' \in \{ +, - \} \). By Lemma 5.2 this walk is either reflectionless or there is a reflectionless walk \( w' \in \mathcal{W}_{j,j'}^{(\tau, \tau')} \) with \( w' \in \mathcal{W}_{j,j'}^{(\sigma, \sigma')} \mathcal{W}_{j,j'}^{(\sigma, \sigma')} \mathcal{W}_{j,j'}^{(\sigma, \sigma')} \mathcal{W}_{j,j'}^{(\sigma, \sigma')} \) such that \( w \) can be obtained from \( w' \) by one of relations 5.3.
Applying Lemma 5.3 to the walk \( w \) in the first case and to the walk \( w' \) in the second case we obtain that the corresponding contribution to the sum in (5.2) is positive. Hence, the leading term on the r.h.s. of (5.2) is positive for all sufficiently large \( \kappa > 0 \).

6. Positivity Preserving Heat Semigroups

Since \(-\Delta(M, g)\) is bounded from below, the heat semigroup \( \exp\{t\Delta(M, g)\} \) defined by the spectral theorem is a bounded operator.

**Lemma 6.1.** The heat semigroup \( \exp\{t\Delta(M, g)\} \) associated with the Laplace operator \(-\Delta(M, g)\) is the integral operator with \((|I| + |E|) \times (|I| + |E|)\) matrix-valued integral kernel \( p_t(x, y; M, g) \). The integral kernel is bounded for every \( t > 0 \), that is, for any \( t > 0 \) there is a constant \( C_t > 0 \) such that the bound

\[
||p_t(x, y; M, g)||_{j,j'} \leq C_t
\]

holds for all \( x, y \in \times_{j \in E \cup I} \bar{I}_j \) and all \( j, j' \in E \cup I \). Moreover, it is infinitely differentiable for all \( x, y \in \times_{j \in E \cup I} \bar{I}_j \).

Recall that \( \bar{I}_j \) denote the interior of \( I_j \).

The integral kernel \( p_t(x, y; M, g) \) is called the heat kernel associated with the Laplace operator \( \Delta(M, g) \). If \( I = \emptyset \) we will write \( p_t(x, y; M) \).

For any \( p \in [1, \infty] \) we set

\[
L^p(M) := \{ \psi_j \}_{j \in E \cup I} | \psi_j \in L^p(I_j) \}.
\]

**Proof of Lemma 6.1.** Choose \( \kappa > 0 \) so large that \(-\kappa^2 < \inf \operatorname{spec}(-\Delta(M, g)) \). Then

\[
\exp\{t\Delta(M, g)\} = (\Delta(M, g) - \kappa^2)^{-1}(\Delta(M, g) - x^2)\exp\{t\Delta(M, g)\}.
\]

By the spectral theorem \((\Delta(M, g) - \kappa^2)\exp\{t\Delta(M, g)\}\) is bounded as a map from \( L^2(G) \) to itself. By Lemma 4.2 the resolvent \((-\Delta(M, g) - \kappa \to)^{-1}\) maps \( L^2(G) \) into \( L^\infty(G) \). By a general theory of Carleman operators, it follows that the heat semigroup \( \exp\{t\Delta(M, g)\} \) is the integral operator with essentially bounded integral kernel.

To establish smoothness, we note that by a similar argument

\[
(-\Delta_{M_{\alpha\beta}} + \kappa^2)^n \exp\{t\Delta_{M_{\alpha\beta}}\}(-\Delta_{M_{\alpha\beta}} + \kappa^2)^n
\]

is a bounded map from \( L^2(G) \) into \( L^\infty(G) \) for all \( n \in \mathbb{N} \) and all \( \kappa > 0 \). Thus, (6.1) is an integral operator with essentially bounded integral kernel. This implies that

\[
\left( -\frac{d^2}{dx_j^2} + \kappa^2 \right)^n \left( -\frac{d^2}{dy_{j'}^2} + \kappa^2 \right)^n [p_t(x, y; M, g)]_{j,j'}
\]

is bounded for almost all \( x_j \in \bar{I}_j \) and \( y_{j'} \in \bar{I}_{j'} \). \( \square \)

The self-adjointness of \( \Delta(M, g) \) implies the following symmetry relation of the heat kernel

\[
p_t(y, x; M, g) = p_t(x, y; M, g)^\dagger.
\]

For special graphs and special boundary conditions (see [2], [4], [8], [9] as well as Section 7 below) the integral kernel of the heat semigroup can be computed explicitly.
Definition 6.2. \( \psi \equiv \{ \psi_j \}_{j \in \mathcal{I} \cup \mathcal{E}} \in \mathcal{H} \) is called nonnegative, in symbols \( \psi \geq 0 \), if \( \psi_j(x) \geq 0 \) for Lebesgue almost all \( x \in I_j \) for any \( j \in \mathcal{I} \cup \mathcal{E} \). The semigroup \( \exp \{ t \Delta(M, \mathcal{A}) \} \) is called positivity preserving if \( \exp \{ t \Delta(M, \mathcal{A}) \} \psi \geq 0 \) holds for all nonnegative \( \psi \in \mathcal{H} \).

Theorem 6.3. (i) If \( \mathcal{M} \) is strictly positive, then the heat semigroup \( e^{t \Delta(M, \mathcal{A})} \) associated with the Laplace operator \( \Delta(M, \mathcal{A}) \) is positivity preserving for all \( t > 0 \). If \( \mathcal{I} = \emptyset \) it suffices to assume that \( \mathcal{M} \) is positive.

(ii) If \( \mathcal{M} \) is locally strictly positive and the graph \( \mathcal{G} \) has no tadpoles, then the heat semigroup \( e^{t \Delta(M, \mathcal{A})} \) associated with the Laplace operator \( \Delta(M, \mathcal{A}) \) is positivity preserving for all \( t > 0 \).

Proof of Theorem 6.3. Using the operator-valued Euler formula \( \Delta(t) \equiv \frac{1}{\sin(\pi t)} \Delta(M, \mathcal{A}) + 1 \equiv \frac{1}{\sin(\pi t)} \Delta(M, \mathcal{A}) + \pi^2 \equiv \pi^2 e^{t \Delta(M, \mathcal{A})} \),

the claim (i) follows from Theorem 4.6 and the claim (ii) from Theorem 5.1.

Proposition 6.4. Assume that \( \mathcal{I} = \emptyset \). If \( \mathcal{M} \) is strictly positive, then the smallest eigenvalue \( \lambda \leq 0 \) of \( -\Delta(M) \) is simple.

Proof. We call \( \psi \equiv \{ \psi_j \}_{j \in \mathcal{E}} \) positive, in symbols \( \psi > 0 \), if \( \psi_j(x_j) > 0 \) for Lebesgue almost all \( x_j \in I_j \) for any \( j \in \mathcal{E} \). Observe that by Lemma 4.2 and Theorem 4.6 the resolvent \( (-\Delta(M) + \kappa^2)^{-1} \) is positivity improving for all \( \kappa > \sqrt{\lambda} \), that is,

\[
(-\Delta(M) + \kappa^2)^{-1} \psi > 0
\]

holds for all \( \psi \geq 0 \). Applying Theorem XIII.44 in [21] we obtain the claim.

7. Some Examples

Throughout this section we assume that the connected graph \( \mathcal{G} \) has no internal edges, \( \mathcal{G} = \{ \{ v \}, \emptyset, \mathcal{E}, \partial \} \) with \( \deg(v) = |\mathcal{E}| \geq 1 \).

For standard boundary conditions (see Example 4.3) the heat kernel has been calculated in [22]:

\[
[p_t(x,y;M)]_{e,e'} = \begin{cases} 
g_t(x_e - y_e) - \frac{\deg(v) - 2}{\deg(v)} g_t(x_e + y_e), & e = e', \\
\frac{2}{\deg(v)} g_t(x_e + y_{e'}), & e \neq e',
\end{cases}
\]

where

\[
g_t(x) = \frac{1}{\sqrt{4\pi t}} \exp\{-x^2/4t\}.
\]

By Theorem 6.3 the heat semigroup associated with the heat kernel \( p_t(x,y) \) is positivity preserving (see Example 4.5). Alternatively, positivity of the heat kernel can be deduced directly from (7.1) using the inequality \( g_t(x_e + y_e) \leq g_t(x_e - y_e) \) for all \( x_e, y_e > 0 \).

Below we will derive an explicit representation for the heat kernel for a class of boundary conditions which to the best of our knowledge has not been treated before. We start with recalling the following well-known result (see, e.g., [5], [6]).
Lemma 7.1. For \( t > 0 \) the function \( h_t(s, \lambda) \), defined in terms of the complementary error function

\[
\text{erfc}(w) = \frac{2}{\sqrt{\pi}} \int_w^\infty e^{-u^2} \, du
\]
as

\[
h_t(s, \lambda) = -\lambda \sqrt{4\pi t} g_t(s) \exp \left\{ \left( \frac{s}{2\sqrt{t}} - \lambda \sqrt{t} \right)^2 \right\} \text{erfc} \left( \frac{s}{2\sqrt{t}} - \lambda \sqrt{t} \right)
\]
satisfies the relations

\[
\partial_t h_t(s, \lambda) - \partial^2_s h_t(s, \lambda) = 0,
\]
\[
\lambda (2g_t(s) - h_t(s, \lambda)) - \partial_s h_t(s, \lambda) = 0.
\]

From the well-known asymptotic expansion of the error function \[1\] Equation 7.2.14] we obtain the asymptotics

\[
h_t(s, \lambda) = -\frac{4\lambda t}{s} g_t(s) (1 + O(t)),
\]
which holds for small \( t > 0 \) and fixed \( s > 0 \).

Assume that the maximal isotropic subspace \( \mathcal{M} \subset dK \) is defined by the self-adjoint \( A = H \) and \( B = I \) via relation (2.8). Then

\[
\mathcal{G}(k; \mathcal{M}) = -\frac{H - ik}{H + ik}
\]
such that

\[
I + \mathcal{G}(ik; \mathcal{M}) = 2i(k - H)^{-1}.
\]

Observe that the maximal isotropic subspace \( \mathcal{M}(H, I) \) is positive if either \( H \succ 0 \) or all off-diagonal matrix elements of \( H \) are positive. Indeed, for sufficiently large \( \varkappa \) we have the absolutely convergent expansion

\[
I + \mathcal{G}(i\varkappa; \mathcal{M}) = 2 \sum_{n=0}^{\infty} \left( \frac{H}{\varkappa} \right)^n.
\]

If \( H \succ 0 \) this sum is nonnegative. If all off-diagonal matrix elements of \( H \) are positive, then \( H \succ -cI \) for some \( c \geq 0 \). Thus,

\[
I + \varkappa^{-1}H \succ 0
\]
holds for all \( \varkappa > c \). This implies that \( I + \mathcal{G}(i\varkappa; \mathcal{M}) \succ 0 \) for all sufficiently large \( \varkappa > 0 \).

For any \( e, e' \in \mathcal{E} \) consider

\[
f_t^{(e,e')}(s) := [h_t(s, H)]_{e,e'},
\]
where the matrix-valued function \( h_t(s, H) \) is defined by \[12\] via the spectral theorem.

Theorem 7.2. Assume that the maximal isotropic subspace \( \mathcal{M} \subset dK \) is defined by the self-adjoint \( A = H \) and \( B = I \) via relation (2.8). The heat kernel \( p_t(x, y; \mathcal{M}) \) of \(-\Delta(\mathcal{M})\) is given by

\[
[p_t(x, y; \mathcal{M})]_{e,e'} = g_t(x_e - y_e) \delta_{e,e'} + g_t(x_e + y_e) \delta_{e,e'} - f_t^{(e,e')}(x_e + y_e).
\]
For small $t > 0$ and fixed $x, y$ the following asymptotics holds

$$[p_t(x, y; M)]_{e,e'} = g_t(x_e - y_e) \delta_{e,e'} + g_t(x_e + y_e) \delta_{e,e'}$$

(7.6)

$$+ \frac{4t H_{e,e'}}{(x_e + y_e)} g_t(x_e + y_e)(1 + O(t)).$$

Proof. Obviously, the integral kernel (7.5) satisfies the symmetry relation (6.2). Set for brevity

(7.7) $P^{(e,e')}_t(x_e, y_{e'}) := g_t(x_e - y_e) \delta_{e,e'} + g_t(x_e + y_e) \delta_{e,e'} - f^{(e,e')}_t(x_e + y_{e'}).$

By Lemma (7.1) for any $e, e' \in \mathcal{E}$ the function $P^{(e,e')}_t(x_e, y_{e'})$ solves the heat conduction equation

$$\partial_t P^{(e,e')}_t(x_e, y_{e'}) = \Delta_{x_e} P^{(e,e')}_t(x_e, y_{e'}).$$

Therefore, we need only to check that (7.7) satisfies the boundary conditions (2.14) with $A = H$ and $B = \Pi$.

From (7.3) we get

$$\partial_s h_t(s; H) + H h_t(s; H) = 2g_t(s) H.$$

Therefore,

(7.8) $\partial_{y_{e'}} f^{(e,e')}_t(y_{e'}) + \sum_{e'' \in \mathcal{E}} H_{e,e''} f^{(e'',e')}_t(y_{e'})|_{x_e=0} = 2g_t(y_{e'}) H_{e,e'}$.

Equation (7.7) implies that

$$P^{(e,e')}_t(x_e, y_{e'})|_{x_e=0} = 2g_t(y_{e'}) \delta_{e,e'} - f^{(e,e')}_t(y_{e'})$$

and

$$\partial_{x_e} P^{(e,e')}_t(x_e, y_{e'})|_{x_e=0} = -\partial_{y_{e'}} f^{(e,e')}_t(y_{e'}).$$

From (7.3) it follows that

$$\sum_{e'' \in \mathcal{E}} H_{e,e''} P^{(e'',e')}_t(x_e, y_{e'})|_{x_e=0} + \partial_{x_e} P^{(e,e')}_t(x_e, y_{e'})|_{x_e=0}$$

$$= 2g_t(y_{e'}) H_{e,e'} - \sum_{e'' \in \mathcal{E}} H_{e,e''} f^{(e'',e')}_t(y_{e'}) - \partial_{y_{e'}} f^{(e,e')}_t(y_{e'}) = 0$$

holds for all $y_{e'} > 0$. This proves the equality (7.5). The asymptotics (7.6) follows from (7.4). □

In particular, the asymptotics (7.6) implies that for small $t > 0$ the heat kernel is non-negative whenever $H \succ 0$.
