Abstract

We determine the $\nu_R$ Majorana mass matrix from the experimental data on neutrino oscillations in the framework of a see-saw SO(10) model, where we impose the condition $(M^R)_{33} = 0$ to avoid too large fine-tunings in the see-saw formula. We find a class of solutions with the two lowest neutrino masses almost degenerate and the scale of the matrix elements of $M^R$ in the range $10^{11} - 10^{12}$ GeV in agreement with Pati-Salam intermediate symmetry. We find also solutions with smaller neutrino masses, for which the scale of $M_R$ depends on the solution to the "solar neutrino problem" and on the value of the component of $\nu_e$ along the highest mass eigenstate, $U_{e3}$.
1 Introduction

The evidence in favour of oscillations\(^1\) of solar\(^2\) and atmospheric\(^3\) neutrinos with square mass differences orders of magnitude smaller than the square masses of the other fermions strongly supports SO(10) gauge unification\(^4\), where the see-saw mechanism\(^5\) naturally accounts for this large mass gap. In this framework it is important to establish the order of magnitude of the elements of the \(\nu_R\)'s Majorana mass matrix, which is related to the scale of the spontaneous symmetry breaking of the SO(10) generator, B - L\(^6\).

In the following section we shall show the uncertainties for the \(\nu_L\) effective Majorana mass matrix, which follow not only from the presence of different solutions to the "solar neutrino problem"\(^7\), but also from not knowing the mass of the lightest neutrino mass eigenstate and the relative sign of the three mass eigenvalues. We shall also show that an expansion in the eigenvalues of the Dirac neutrino mass matrix, assumed to be hierarchically ordered according to the family as the other fermions, is unable to reproduce with the first two terms the phenomenological properties of the \(\nu_L\) effective Majorana mass-matrix, if small mixing angles for the Dirac mass matrices are assumed for leptons in analogy with what we know about the CKM matrix\(^8\) for quarks.

This fact motivates us to take in the third section a vanishing value for \(M_{33}^R\), \(^9\)\(^10\)\(^11\). Within the simplifying assumption of a trivial mixing matrix for the Dirac leptons, we are able to implement that condition for all the different solutions of the "solar neutrino problem". In most cases we find solutions with the two lower masses almost degenerate and at the order of magnitude of the highest one and with the highest matrix element of \(M_{23}^R, M_{33}^R\), in the range \(10^{11} - 10^{12}\) GeV in good agreement with the scale of the spontaneous breaking of B-L, \(2.7 \cdot 10^{11}\) GeV\(^12\) in the model with SU(4)xSU(2)xSU(2)\(^13\) intermediate symmetry. We find also solutions with the two lower masses at the order \(\sqrt{\Delta m_{\text{sun}}^2}\) and in that case the order of magnitude of the largest matrix element of \(M^R\) depends on the solution to the "solar neutrino problem" and on the value of \(U_{e3}\).

Finally we give our conclusions.

2 The effective \(\nu_L\) Majorana mass matrix.

The experimental information from solar and atmospheric neutrinos is such to ”almost” allow a model-independent determination of the neutrino mass matrix, within the hypothesis of the existence of only the three active Majorana neutrinos and CP symmetry. The second hypothesis is expected to be at most an approximation, since CP violation in the neutral kaon system most probably comes from a phase in the CKM matrix, as is confirmed by the indication of a large CP-violating asymmetry in the \(J/\psi K^S\)\(^14\) chan-
nel, and a similar phase may be present in the lepton sector, for which, with Majorana neutrinos, two other CP-violating phases are also allowed.

The incompleteness in the determination of the neutrino mass matrix arises from the following facts:

i) Up to now there is only an upper limit for $|U_{e3}|^2 (\leq 0.05)$ [15] [16].

ii) Oscillations depend on $\Delta m^2$'s and cannot by themselves determine the masses of the neutrino eigenstates.

iii) There are sign ambiguities in the mass-eigenvalues.

Moreover there are five solutions [7] of the “neutrino solar problem” with the oscillation parameters reported in Table I.

| Scenario | $\Delta m^2_{ij}$ eV$^2$ | $\sin^2(2\theta_s)$ | C.L. |
|----------|------------------------|-------------------|------|
| LMA      | $2.7 \cdot 10^{-5}$    | 0.79              | 68%  |
| SMA      | $5.0 \cdot 10^{-6}$    | 0.72 $\cdot 10^{-2}$ | 64%  |
| LOW      | $1.0 \cdot 10^{-7}$    | 0.91              | 83%  |
| VAC$S$   | $6.5 \cdot 10^{-11}$   | 0.72              | 90%  |
| VAC$L$   | $4.4 \cdot 10^{-10}$   | 0.90              | 95%  |

Table I

For atmospheric neutrino oscillations the relevant parameters are [3]:

$$\Delta m^2_a \simeq 3.5 \cdot 10^{-3} (eV)^2 \quad \sin^2(2\theta_a) \simeq 1$$ (2.1)

We shall use this information to determine the effective $\nu_L$ Majorana mass matrix.

By assuming CP symmetry, which implies a real symmetric $3 \times 3$ Majorana neutrino mass matrix $M^L$:

$$M^L = (m_{ij})_{i,j=1,2,3}$$

$$= \Sigma |m_i > m_i < m_i|$$ (2.2)

where the eigenvalues $m_i$ are real, not necessarily positive, numbers.

Our convention is

$$|m_3| > |m_2| > |m_1|$$ (2.3)

and we may take $m_3 > 0$, since an overall change of sign of $M^L$ has no physical consequences.
We define

\[
\begin{align*}
|m_3| &= \sin \psi |\nu_e| + \cos \psi (|\nu_\mu| + \sin \theta |\nu_\tau|) \\
|m_2| &= -\sin \chi |v_1| + \cos \chi |v_2| \\
|m_1| &= \cos \chi |v_1| + \sin \chi |v_2|
\end{align*}
\] (2.4)

where

\[
\begin{align*}
|v_1| &= \cos \psi |\nu_e| - \sin \psi (|\nu_\mu| + \sin \theta |\nu_\tau|) \\
|v_2| &= -\sin \theta |\nu_\mu| + \cos \theta |\nu_\tau|
\end{align*}
\] (2.5)

The difference \(m_3^2 - m_1^2\) has to be identified with \(\Delta m^2_{\text{atm}}\), while for \(\Delta m^2_{\text{solar}}\) one has two options, either \(m_3^2 - m_2^2\) or \(m_2^2 - m_1^2\). The current interpretation of the atmospheric neutrino anomaly due to a practically maximal mixing between \(\nu_\mu\) and \(\nu_\tau\), with \(\nu_e\) playing a marginal role, would imply with the first choice having \(\nu_e\) components almost completely along the two nearly degenerate higher-mass eigenstates. Since this situation is unnatural in the \(SO(10)\) framework, which we will describe in the second part of this paper, we take the option \(\Delta m^2_{\text{solar}} = m_2^2 - m_1^2\).

From eqs. 2.2, 2.4 and 2.5, it is easy to get:

\[
\begin{align*}
m_{11} &= m_3 \sin^2 \psi + m_3 \sin^2 \chi \cos^2 \psi + m_1 \cos^2 \chi \cos^2 \psi \\
m_{22} &= m_3 \cos^2 \theta \cos^2 \psi + \cos^2 \theta \sin^2 \psi (m_2 \sin^2 \chi + m_1 \cos^2 \chi) \\
&+ \sin^2 \theta (m_2 \cos^2 \chi + m_1 \sin^2 \chi) - \sin 2\theta \sin 2\chi \frac{\sin \psi}{2} (m_2 - m_1) \\
m_{33} &= m_3 \sin^2 \theta \cos^2 \psi + \sin^2 \theta \sin^2 \psi (m_2 \sin^2 \chi + m_1 \cos^2 \chi) \\
&+ \cos^2 \theta (m_2 \cos^2 \chi + m_1 \sin^2 \chi) + \sin 2\theta \sin 2\chi \frac{\sin \psi}{2} (m_2 - m_1) \\
m_{12} &= \cos \psi \left[ \sin \psi \cos \theta (m_3 - m_2 \sin^2 \chi - m_1 \cos^2 \chi) \\
&+ \sin \theta \frac{\sin 2\chi}{2} (m_2 - m_1) \right] \\
m_{13} &= \cos \psi \left[ \sin \psi \sin \theta (m_3 - m_2 \sin^2 \chi - m_1 \cos^2 \chi) \\
&- \cos \theta \frac{\sin 2\chi}{2} (m_2 - m_1) \right] \\
m_{23} &= \frac{\sin 2\theta}{2} \left[ m_3 \cos^2 \psi - m_2 \cos^2 \chi - m_1 \sin^2 \chi \\
&+ \sin^2 \psi (m_2 \sin^2 \chi + m_1 \cos^2 \chi) \right] \\
&+ \cos 2\theta \frac{\sin 2\chi}{2} \sin \psi (m_2 - m_1)
\end{align*}
\] (2.6)

The angles \(\theta\) and \(\chi\) should be identified with the mixing angles for atmospheric and solar neutrino oscillations, respectively. The experimental value
found for the atmospheric neutrino oscillations, $\sin^2 2\theta_a \simeq 1$, and the upper limit on $|U_{e3}|^2$ imply $\theta = \frac{\pi}{4}$ and a small value for $\sin \psi$.

With hierarchical neutrino masses

$$ m_3 >> |m_2| >> |m_1| \quad (2.7) $$

one has

$$ m_3^2 \simeq \Delta m_a^2 \quad m_2^2 \simeq \Delta m_s^2 \quad (2.8) $$

and by taking $\psi = 0$ for the contributions proportional to $m_2$ and neglecting $|m_1| << \sqrt{\Delta m_s^2}$, one gets:

$$ M^L = \frac{m_3}{2} \cos^2 \psi \begin{pmatrix} 2 \tan \psi^2 & \sqrt{2} \tan \psi & \sqrt{2} \tan \psi \\ \sqrt{2} \tan \psi & 1 & 1 \\ \sqrt{2} \tan \psi & 1 & 1 \end{pmatrix} $$

$$ + \frac{m_2}{2} \cos^2 \chi \begin{pmatrix} 2 \tan^2 \chi & \sqrt{2} \tan \chi & -\sqrt{2} \tan \chi \\ \sqrt{2} \tan \chi & 1 & -1 \\ -\sqrt{2} \tan \chi & -1 & 1 \end{pmatrix}. \quad (2.9) $$

We now consider the possibility, often advocated, that the two lower masses are almost degenerate and larger than $\sqrt{\Delta m_s^2}$, but smaller than $\sqrt{\Delta m_a^2}$ \[10\] \[11\]. In that case, one has still $\Delta m_a^2 = m_3^2$, but we can neglect $\Delta m_{sun}^2$ with respect to $m_1^2$ and $m_2^2$. The first term in eq. (2.9) remains the same, while the other one takes a different form, depending on the relative sign of $m_2$ and $m_1$. We will consider $m_1 m_2 < 0$, since this assumption will be necessary in the following and get

$$ m_2 \cos 2\chi \begin{pmatrix} 1 & \sqrt{2} \tan 2\chi & -\sqrt{2} \tan 2\chi \\ \sqrt{2} \tan 2\chi & 1 & -1 \\ -\sqrt{2} \tan 2\chi & -1 & 1 \end{pmatrix} \quad (2.10) $$

Again for the term proportional to $m_2$ in eq. (2.10) we made the approximation to take $\psi = 0$.

We now consider the possibility advocated by Georgi and Glashow \[17\], with the motivation of having a sizeable neutrino contribution to the hot dark matter, of almost degenerate square masses for the neutrinos, larger than their differences. We have four options, according to the relative signs of the $m_i$’s. By taking again $m_1 < 0 < m_2$ and $\psi = 0$ for the part proportional to $\Delta m_a^2$, we get:

$$ M^L = m_3 \cos^2 \chi \begin{pmatrix} \tan^2 \chi - 1 & \sqrt{2} \cos \psi \tan \chi & -\sqrt{2} \cos \psi \tan \chi \\ \sqrt{2} \cos \psi \tan \chi & 1 & -\tan^2 \chi \\ -\sqrt{2} \cos \psi \tan \chi & \tan^2 \chi & 1 \end{pmatrix} $$
+ $m_3 \cos^2 \chi \sin \psi \left( \begin{array}{ccc}
0 & \sqrt{2} \cos \psi & \sqrt{2} \cos \psi \\
\sqrt{2} \cos \psi & -2 \tan \chi & 0 \\
\sqrt{2} \cos \psi & 0 & 2 \tan \chi, 
\end{array} \right)$

+ $2m_3 \cos^2 \chi \sin^2 \psi \left( \begin{array}{ccc}
1 & 0 & 0 \\
0 & -\frac{1}{2} & -\frac{1}{2} \\
0 & -\frac{1}{2} & -\frac{1}{2}, 
\end{array} \right)$

+ $\frac{\Delta m^2_s \cos 2\chi}{4m_3} \left( \begin{array}{ccc}
\frac{2}{\sqrt{2}} \tan 2\chi & -\sqrt{2} \tan 2\chi & -\sqrt{2} \tan 2\chi \\
-\sqrt{2} \tan 2\chi & 1 & 1 \\
-\sqrt{2} \tan 2\chi & 1 & 1, 
\end{array} \right)$ \hspace{1cm} (2.11)

Let us consider

\[ m_{\nu_e\nu_e} = m_3 (-\cos 2\chi + 2 \cos^2 \chi \sin^2 \psi) \]

\[ + \sin^2 \chi \frac{\Delta m^2_s}{2m^2_3} + \frac{\Delta m^2_a}{2m^2_3} \cos^2 \chi \] \hspace{1cm} (2.12)

for which there is an experimental upper limit coming from the study of neutrinoless double beta-decay $|m_{\nu_e\nu_e}| < .2 \text{ eV}$ \cite{19}. To get the cancellation between $-\cos 2\chi$ and $2 \cos^2 \chi \sin 2\psi$, $\chi$ should be near to $\frac{\pi}{4}$, more precisely:

\[ \sin^2 \psi = \frac{\tan^2 \chi - 1}{2} \] \hspace{1cm} (2.13)

But the r.h.s. of eq. 2.13 takes at least the central value .22 (for $\sin^2 2\theta_s = .91$), larger than the upper limit for $\sin^2 \psi$, which implies \cite{18}

\[ |m_3| \simeq \left| \frac{m_{\nu_e\nu_e}}{2 \cos^2 \chi \sin^2 \psi - \cos 2\chi} \right| \leq .85 \text{ eV} \] \hspace{1cm} (2.14)

The situation is similar for the case with $m_1 > 0 > m_2$. In conclusion many options are open for the neutrino mass matrix and even an exact determination of the mixing matrix and of the square mass differences is unable to resolve the ambiguity associated to the value of $|m_1|$ and to the relative signs of the masses \cite{20}. Also the same Majorana mass matrix for the $\nu_L$’s may be obtained with different choices of the Dirac lepton matrices and of $M^R$.

It has been suggested since a long time \cite{21} that the peculiar properties of neutrino mixing, almost maximal for atmospheric, rather large for all the solutions to the “solar neutrino problem”, except the MSW small angle solution, should be related to the fact that, differently from the case for the charged fermions, their masses arise from the see-saw mechanism \cite{5}. The later has the indisputable merit of providing a reason for the small value of the neutrino masses, especially in the framework of $SO(10)$ unified theories, which predict the existence of left-handed antineutrinos with Majorana masses related to the spontaneous breaking of $B - L$ symmetry \cite{1}.

Unified $SO(10)$ theories are suitable for the study of fermion masses as all the fermions of one family belong to a single representation, the spinorial
Indeed, by classifying the Higgs doublet responsible for the breaking of the electroweak symmetry in the vector representation (10), one obtains, together with the celebrated (but actually not so successful) relationship [22],

\[ \frac{m_r}{m_b} (\text{unification}) = 1 \]  

(2.15)

while the analogous relationship, \( \frac{m_\nu}{m_\tau} (\text{unification}) = 1 \), is turned by the seesaw mechanism into the intriguing prediction of very small neutrino masses. To correct \( \frac{m_\mu}{m_s} = \frac{m_\mu}{m_d} = 1 \), some component of the electroweak Higgs, at least along the 126, should be introduced [23]

\[
\begin{align*}
(16 \times 16)_S &= 126 + 10 \\
(16 \times 16)_A &= 120
\end{align*}
\]  

(2.16)

Without adopting a particular scheme, we shall limit ourselves to assume that the Dirac neutrino mass matrix, once diagonalized by the biunitary transformation, gives rise to a hierarchical relationship for the elements of the diagonal matrix similar to that existing for the other fermions, and the matrix corresponding to the CKM, which gives the misalignment with the corresponding leptons, has small non diagonal matrix elements.

\[
\begin{align*}
M^L &= -m^D (M^R)^{-1} (m^D)^T \\
m^D &= U_L m_{\text{diag}} U_R^+
\end{align*}
\]  

(2.17)

with

\[ m_{\text{diag}} = \text{diag}(\mu_1, \mu_2, \mu_3) \]  

(2.18)

and we assume \( \mu_1 << \mu_2 << \mu_3 \). From eqs. 2.17 it is easy to derive:

\[
M^L = -U_L m_{\text{diag}} U_R^+ (M^R)^{-1} U_R^* m_{\text{diag}} U_L^T
\]  

(2.19)

which is simplified by defining

\[ \tilde{N} = U_R^+ M^{R^{-1}} U_R^* \]  

(2.20)

into

\[
M^L = -U_L m_{\text{diag}} \tilde{N} m_{\text{diag}} U_L^T
\]  

(2.21)

With our hypothesis of CP conservation, \( U_R \) and \( U_L \) are, in fact, real orthogonal matrices and \( \tilde{N} \) is symmetric real. We may develope \( M^L \) as a quadratic form in the \( \mu_i \)’s:

\[
- M^L_{\ell\ell'} = (U_L)_{\ell 3} (U_L)_{\ell' 3} \tilde{N}_{33} \mu_3^2 \\
+ ((U_L)_{\ell 2} (U_L)_{\ell' 3} + (U_L)_{\ell 3} (U_L)_{\ell' 2}) \tilde{N}_{23} \mu_2 \mu_3 \\
+ (U_L)_{\ell 2} (U_L)_{\ell' 2} \tilde{N}_{22} \mu_2^2 + \cdots
\]  

(2.22)
Should the matrix elements of $\tilde{N}$ be of the same order, it would be a reasonable approximation to take only the terms proportional to $\mu_3^2$, which would give for $-M^L$ the expression:

$$
\tilde{N}_3 \mu_3^2 \begin{pmatrix}
(U_L)_{13}^2 & (U_L)_{13}(U_L)_{23} & (U_L)_{13}(U_L)_{33} \\
(U_L)_{13}(U_L)_{23} & (U_L)_{23}^2 & (U_L)_{23}(U_L)_{33} \\
(U_L)_{13}(U_L)_{33} & (U_L)_{23}(U_L)_{33} & (U_L)^2_{33}
\end{pmatrix}
$$

(2.23)

The matrix defined by eq. (2.23) should have eigenvalues $\mu_3^2 \tilde{N}_3$, corresponding to the eigenvector

$$
\begin{pmatrix}
U_{13} \\
U_{23} \\
U_{33}
\end{pmatrix},
$$

(2.24)

and twice the eigenvalue 0. The eigenvector in eq. (2.24) should be identified with:

$$
\begin{pmatrix}
\sin \psi \\
\cos \psi \cos \theta \\
\cos \psi \sin \theta
\end{pmatrix},
$$

(2.25)

which, for $\theta = \frac{\pi}{4}$, has almost equal second and third components, implying $U_{23} \approx U_{33}$, in disagreement with our assumption that the mixing angles of Dirac neutrinos with the corresponding leptons are small.

Let us consider also the term proportional to $\mu_2 \mu_3$, and, for brevity, define:

$$
M = \tilde{N}_3 \mu_3^2 \\
\tilde{M} = \tilde{N}_3 \mu_2 \mu_3.
$$

(2.26)

In such a case, the neutrino mass matrix would be:

$$
M \begin{pmatrix}
(U_L)_{13}^2 & (U_L)_{13}(U_L)_{23} & (U_L)_{13}(U_L)_{33} \\
(U_L)_{13}(U_L)_{23} & (U_L)_{23}^2 & (U_L)_{23}(U_L)_{33} \\
(U_L)_{13}(U_L)_{33} & (U_L)_{23}(U_L)_{33} & (U_L)^2_{33}
\end{pmatrix}
$$

(2.27)

$$
+ \tilde{M} \begin{pmatrix}
2(U_L)_{13}(U_L)_{12} & (U_L)_{13}(U_L)_{22} + (U_L)_{12}(U_L)_{23} & (U_L)_{12}(U_L)_{33} + (U_L)_{13}(U_L)_{32} \\
(U_L)_{13}(U_L)_{22} + (U_L)_{12}(U_L)_{23} & 2(U_L)_{22}(U_L)_{33} & (U_L)_{22}(U_L)_{33} + (U_L)_{23}(U_L)_{32} \\
(U_L)_{12}(U_L)_{33} + (U_L)_{13}(U_L)_{32} & (U_L)_{22}(U_L)_{33} + (U_L)_{23}(U_L)_{32} & 2(U_L)_{32}(U_L)_{33}
\end{pmatrix}
$$

which has a vanishing eigenvalue and the other two given by:

$$
M \pm \sqrt{M^2 + 4\tilde{M}^2} \over 2
$$

(2.28)

By taking $M$ positive, one should identify

$$
\Delta m^2_a = \frac{1}{4} [M + \sqrt{M^2 + 4\tilde{M}^2}]^2,
$$

(2.29)
while for $\Delta m_s^2 \ll \Delta m_a^2$ one should have

$$\Delta m_s^2 = \frac{1}{4} \left[ \sqrt{M^2 + 4\tilde{M}^2} - M \right]^2 \quad (2.30)$$

$$\frac{\Delta m_s^2}{\Delta m_a^2} \simeq \frac{\Delta m_s^2 \Delta m_a^2}{(\Delta m_a^2)^2 + (\Delta m_s^2)^2} = \frac{2\tilde{M}^4}{2M^4 + 8M^2\tilde{M}^2 + 4\tilde{M}^4} \simeq \left( \frac{\tilde{M}}{M} \right)^4 \quad (2.31)$$

In the most favourable case, large angle MSW, it would give:

$$\left( \frac{\tilde{M}}{M} \right) = \left( \frac{1.6 \cdot 10^{-5}}{3.5 \cdot 10^{-3}} \right)^{\frac{1}{4}} \approx \frac{1}{3.8} \quad (2.32)$$

Let us see how large the non-diagonal matrix elements of $U_L$ should be in order to give rise to a neutrino mass matrix, which has the property of having almost equal matrix elements in 22 and 33 positions. We should have

$$M (U_L)_{23}^2 + 2\tilde{M} (U_L)_{23}(U_L)_{22} = M(U_L)_{33}^2 + 2\tilde{M}(U_L)_{33}(U_L)_{32} \quad (2.33)$$

which is impossible to obtain with small values of the non-diagonal matrix elements, since

$$(U_L)_{23}(M(U_L)_{23} + 2\tilde{M}(U_L)_{22} \ll (U_L)_{33}(M(U_L)_{33} + 2\tilde{M}(U_L)_{32}) \quad (2.34)$$

So the expansion with only the two terms is not able to reproduce a neutrino mass matrix consistent with the experimental information. Therefore, we must now consider further terms, i.e., those proportional to $\mu_2^2$ and to $\mu_1\mu_3$. If we define:

$$\sigma = \tilde{N}_{22} \mu_2^2 \quad \tau = \tilde{N}_{13} \mu_1 \mu_3$$

in the limit $(U_L)_{ij} = \delta_{ij}$, we would just find the matrix proposed by Stech\cite{10}

$$\begin{pmatrix} 0 & 0 & \tau \\ 0 & \sigma & \mu \\ \tau & \mu & M \end{pmatrix} \quad (2.35)$$

which, to reproduce the maximal mixing for $\nu_\mu$ and $\nu_\tau$, requires the equality of the terms proportional to $\mu_2^2$ and $\mu_3^2$, respectively.

From this discussion it follows that the term proportional to $\mu_3^2$ does not play a dominant role in the effective $\nu_e$ Majorana mass matrix not only with respect to the one proportional to $\mu_2 \mu_3$, but also with respect to the one
proportional to $\mu_2^2$. For a diagonal lepton Dirac matrix the term $\mu_3^2$ appears in the expression of $M_{33}^L$, multiplied by $(M^{-1})_{33}$. So to reduce the contribution of $\mu_3^2$ we take a small value for $(M^{-1})_{33}$.

In the following section we shall impose the vanishing of $(M^{-1})_{33}$ and consequently of $(M^R)_{33}$ with a diagonal neutrino Dirac matrix given by:

$$m^D_{\nu} = \frac{m_\tau}{m_b} \text{diag}(m_u, m_c, m_t) \quad (2.37)$$

3 See-Saw model in SO(10) with diagonal neutrino Dirac matrix and $M_{33}^R = 0$

We have seen in the previous section that $M^L$, derived from a Dirac neutrino mass matrix with the properties of the quark mass matrix, hierarchical relationship for its eigenvalues and small mixing angles, is not dominated by the term proportional to $(m^D_{\nu})^2$, which is as important as the term proportional to $(m^D_{\nu})^2$. A way to implement this property, the non-dominance of the term proportional to $(m^D_{\nu})^2$, is found by considering the inverse of the first of eqs. 2.17:

$$M^R = -m^D_{\nu}(M^L)^{-1}m^D_{\nu} \quad (3.1)$$

with $m^D_{\nu}$ given by eq. 2.37:

$$\begin{align*}
\frac{m_b}{m_\tau m_u} (M^R)_{11} & = -\frac{1}{m_1}(\cos^2 \psi \cos^2 \chi - \frac{1}{m_2} \cos^2 \psi \sin^2 \chi - \frac{1}{m_3} \sin^2 \psi) \\
\frac{m_b}{m_\tau m_c} (M^R)_{12} & = \frac{1}{\sqrt{2m_1}} \cos \psi \cos \chi (\cos \chi \sin \psi + \sin \chi) \\
& - \frac{1}{\sqrt{2m_2}} \cos \psi \sin \chi (\cos \chi - \sin \psi \sin \chi) - \frac{1}{2\sqrt{2m_3}} \sin(2\psi) \\
\frac{m_b}{m_\tau m_t} (M^R)_{13} & = \frac{1}{\sqrt{2m_1}} \cos \psi \cos \chi (\cos \chi \sin \psi - \sin \chi) \\
& + \frac{1}{\sqrt{2m_2}} \cos \psi \sin \chi (\cos \chi + \sin \psi \sin \chi) - \frac{1}{2\sqrt{2m_3}} \sin(2\psi) \\
\frac{m_b}{m_\tau m_c} (M^R)_{22} & = -\frac{1}{2m_1}(\cos \chi \sin \psi + \sin \chi)^2 \\
& - \frac{1}{2m_2}(\cos \chi - \sin \psi \sin \chi)^2 - \frac{1}{2m_3} \cos^2 \psi \\
\frac{m_b}{m_\tau m_t} (M^R)_{23} & = \frac{1}{2m_1}(\sin^2 \chi - \cos^2 \chi \sin^2 \psi) \\
& + \frac{1}{2m_2}(\cos^2 \chi - \sin^2 \psi \sin^2 \chi) - \frac{1}{2m_3} \cos^2 \psi
\end{align*}$$

(3.2)
\[
\left(\frac{m_b}{m_t m_t}\right)^2 (M^R)_{33} = -\frac{1}{2m_1} (\sin \chi - \cos \chi \sin \psi)^2 \\
-\frac{1}{2m_2} (\cos \chi + \sin \chi \sin \psi)^2 - \frac{1}{2m_3} \cos^2 \psi
\]

From eqs. 3.3, it is easy to see that
\[
| (M^R)_{11} | < \left( \frac{m_1 m_2}{m_1} \right)^2 \frac{1}{|m_1|} 
\]  
(3.3)

which implies [24], in the absence of cancellations for \((M^R)_{33}\):
\[
\left| \frac{(M^R)_{11}}{(M^R)_{33}} \right| \approx 2 \frac{m_2^2}{m_t^2} \approx 2 \left( \frac{\frac{3}{2} \text{MeV}}{180 \text{GeV}} \right)^2 \approx 4 \cdot 10^{-10} 
\]  
(3.4)

To prevent the appearance of such unnatural small factor we impose the vanishing of the r.h.s of last equation in 3.3:
\[
\frac{(\sin \chi - \cos \chi \sin \psi)^2}{m_1} + \frac{(\cos \chi + \sin \psi \sin \chi)^2}{m_2} + \frac{\cos^2 \psi}{m_3} = 0 
\]  
(3.5)

which requires that not all the \(m_i\)’s have the same sign and
\[
\frac{m_b^2}{m_2^2 m_c m_t} (M^R)_{23} = \frac{\sin 2 \chi \sin \psi}{2} \left( \frac{1}{m_1} - \frac{1}{m_2} \right) \\
- (\sin \psi)^2 \left( \frac{(\cos \chi)^2}{m_1} + \frac{(\sin \chi)^2}{m_2} \right) - \frac{(\cos \psi)^2}{m_3} 
\]  
(3.6)

By neglecting the terms proportional to powers of \(\sin \psi\), we get
\[
| (M^R)_{23} | \leq 7 \cdot 10^{11} \text{GeV} 
\]  
(3.7)

as in [11].

With \(\sin \psi = 0\), eqs. 3.3 read:
\[
\left(\frac{m_b}{m_t m_t}\right)^2 (M^R)_{11} = -\frac{1}{m_1} \cos^2 \chi \\
\left(\frac{m_c}{m_t m_t}\right)^2 (M^R)_{12} = \cos \chi \sin \chi \left( \frac{1}{m_1} - \frac{1}{m_2} \right) \\
\left(\frac{m_c}{m_t m_t}\right)^2 (M^R)_{13} = \cos \chi \sin \chi \left( \frac{1}{m_1} + \frac{1}{m_2} \right) \\
\left(\frac{m_b}{m_t m_t}\right)^2 (M^R)_{22} = -\frac{1}{2m_1} \sin^2 \chi - \frac{1}{2m_2} \cos^2 \chi - \frac{1}{2m_3} \\
\left(\frac{m_c}{m_t m_t}\right)^2 (M^R)_{23} = \frac{1}{2m_1} \sin^2 \chi + \frac{1}{2m_2} \cos^2 \chi - \frac{1}{2m_3} \\
\left(\frac{m_b}{m_t m_t}\right)^2 (M^R)_{33} = -\frac{1}{2m_1} \sin^2 \chi - \frac{1}{2m_2} \cos^2 \chi - \frac{1}{2m_3}
\]  
(3.8)

\footnote{Since the ratios of the quark masses have a negligible dependence on the scale, we can take the values given in [24].}
In order to get \((MR)_{33} = 0\), one should have

\[
\frac{\sin^2 \chi}{m_1} + \frac{\cos^2 \chi}{m_2} + \frac{1}{m_3} = 0 \quad (3.9)
\]

We look for its solutions with \(m_i\)’s constrained by the relations:

\[
m_2^2 = m_1^2 + \Delta m_s^2
\]
\[
m_3^2 = m_1^2 + \Delta m_a^2
\]
(3.10)

With this we do not want to impose that \((MR)_{33}\) vanishes exactly. But, once a solution with no large differences between the matrix elements of \(M^R\) has been found, we can allow for a value of \((MR)_{33}\) of the same order of the other matrix elements, with a small change for the left-handed neutrino Majorana mass matrix.

It is obvious that to obey eq. 3.9, the \(m_i\)’s cannot have the same sign and, as \(|m_3| > |m_2| > |m_1|\), \(m_1\) and \(m_2\) should have opposite signs. This fact has been pointed out in [25]. From eq. 3.9 we get:

\[
\tan^2 \chi = -\frac{m_1(m_3 + m_2)}{m_2(m_3 + m_1)}
\]
(3.11)

which, when \(|m_2| << |m_3|\) simplifies to

\[
\tan^2 \chi = -\frac{m_1}{m_2}
\]
(3.12)

in agreement with the expectation that large mixing angles correspond to almost degenerate masses of the mixed states [26]. One has another approximate solution with almost degenerate lightest neutrino mass eigenstates (\(|m_2| \simeq -m_1 = m\))

\[
m = \cos(2\chi)m_3
\]
(3.13)

These approximate solutions correspond to exact solutions of eq. 3.9. In fact, with equal signs for \(m_2\) and \(m_3\) we may write eq. 3.9 in the form

\[
\sin^2 \chi + \cos^2 \chi \frac{m_1 m_2}{m_3} + \frac{m_1}{m_3} = 0
\]
(3.14)

which has one and only one solution for negative \(m_1\) since its l.h.s. is an increasing function of \(m_1\) in the range \((-\infty, 0)\) varying from \(-2\cos^2 \chi\) to \(\sin^2 \chi\). In the case of the same sign for \(m_1\) and \(m_3\) it is convenient to rewrite eq. 3.9 in the form

---

2Notice that eqs. 3.10 imply that when \(|m_1|\) goes to \(\infty\) the ratios \(\frac{m_1}{m_2}\) and \(\frac{m_1}{m_3}\) go to 1.
\[
\sin^2 \chi \frac{m_2}{m_1} + \cos^2 \chi + \frac{m_2}{m_3} = 0 \tag{3.15}
\]

With its l.h.s., in the range \((-\infty, -\sqrt{\Delta m_2^2})\) for \(m_2\), going from \(-2(\sin^2 \chi)\) to \(-\infty\). But, if \(\cos^2 \chi\) is sufficiently larger than \(\sin^2 \chi\), can reach positive values, implying two solutions for eq. 3.9, approximately given by eqs. 3.12 and 3.13, respectively.

For the MSW solutions one has to take \(\cos^2 \chi > \sin^2 \chi\) and therefore one has three solutions. For the vacuum solutions, which allows both signs for \(\cos(2\chi)\), one has also a solution with \(\sin^2 \chi > \cos^2 \chi\). We wish to extend the previous analysis to consider non vanishing values of \(|\sin \psi|\). In that case, when

\[
(sin \chi - \sin \psi \cos \chi)^2 > (\cos \chi + \sin \psi \sin \chi)^2 \tag{3.16}
\]

one has only one solution of eq. 3.9; instead, when the r.h.s. of the inequality 3.16 is sufficiently larger than the l.h.s. \(+ 1\), there are two solutions. We have performed a numerical study of the solutions of eq. 3.6 with \(|\sin \psi| = k(0.075)\), \(k=0,...,3\). To get a general view of our solutions, we give in Table II, for each solar neutrino oscillation scenario, the matrix where the smallest value for the ratios of the moduli of non-vanishing matrix elements of \(M^R\) (which is, with the only expection of VACL solution, \(M^R_{33}\)) takes the largest value and the ones where the max (i.e. highest) matrix element of \(M^R\) takes the smallest or largest value. From Table II we see that the matrices with smallest excursion for their matrix element correspond to small values for \(m_1^2\) and to \(\psi = 0\), with the only exception of the LMW solution, where \(|\sin \psi| = 0.075\). The matrices with the smallest value of \(M^R_{23}\) are found for the large \(m_1^2\) solutions. Finally the largest values of \(M^R_{23}\) are found at the boundary of the allowed values for \(\psi\) and in correspondence of the small \(m_1^2\) solutions. Since our motivation for setting \(M^R_{33} = 0\) is also based on the demand of dealing with \(M^R\) matrices with not so disparate orders of magnitude for its matrix elements, we favour small \(\psi\) and \(m_1^2\) choices (in particular, the small MSW solution with the ratio between the smallest and the largest matrix elements of \(M^R\) given by \(4.3 \cdot 10^{-4}\)). We never find neutrino masses large enough to be of cosmological relevance. The maximum value found for \(\sum_i |m_i|\) being \(.6\) eV, corresponding to the boundary of allowed values of the small angle MSW solution.

4 Conclusions

The hypothesis of a vanishing \(M^R_{33}\), assumed in[3][10][11] and here motivated by the requirement of not having too large fine tunings in the see-saw formula may be implemented in all five solutions to the "solar neutrino problem". In general one has solutions with large \(\sim (\Delta m_2^2)\) or small \(\sim (\Delta m_3^2)\) for the
square mass of the lightest neutrino mass eigenstate. For large values of $m_1^2$ the max matrix element of $M^R (M^R_{23})$ has a value $\sim 7 \cdot 10^{11} \text{ GeV}$, a scale found in a recent work [11] and in agreement with the spontaneous scale of B-L symmetry breaking found in a SO(10) model [12] with SU(4) x SU(2) x SU(2) intermediate symmetry [13]. Moderate values for the matrix elements of $M^R$ have been also found in [9] [10] and recently by Akhmedov, Branco and Rebelo [27]. For small values for $m_1^2$ one still finds the same order of magnitude for the large angle MSW solution in the entire range of the allowed values for $\psi$; the same happens for the other MSW solutions for $\psi = 0$. The other MSW solutions correspond to larger values for the scales, especially for $|\sin \psi|$. The solutions corresponding to small $m_1^2$ at $\psi=0$ have the appealing feature of having not too different orders of magnitude for the matrix elements of $M^R$.
