ABSTRACT: Mycotoxins are secondary fungal metabolites that contaminate animal feeds, crops and food. Globally, two major foodborne mycotoxins (aflatoxins and fumonisins) have been reported to affect the health and productivity of the poultry industry. Notwithstanding the health risks associated with these mycotoxins, no study has probably investigated the co-occurrence of aflatoxin and fumonisin levels in poultry feed produced in Ghana. The aim of the study was to investigate the levels of total aflatoxin (B1, B2, and G1 and G2) and fumonisin B1 (FB1) levels in poultry feed produced in Ghana. Total aflatoxins and fumonisin B1 were analyzed in 100 poultry feed samples collected from farmers from four major poultry producing regions in Ghana. High performance liquid chromatography (HPLC) was used to measure total aflatoxin levels while a fluorometer reader was used to measure the levels of fumonisin B1. Total aflatoxin and FB1 contaminations were detected in 100% of the feed samples in a range of 0.02-22 ppb and 0.5-4.6 ppm, respectively. Three samples representing, 3% out of the 100 samples screened were detected to have total aflatoxin levels greater than 20 parts per billion Fumonisin levels detected in the poultry feed were within the permissible level of 50 parts per million in poultry feed. Seventy out of the 100 poultry feed samples collected had their feed treated with fungal binders. In present study, we have probably for the first time in Ghana shown the levels of mycotoxins in poultry feed and the need to monitor animal feed made from cereals.

Keywords: Poultry feed, Total aflatoxin, Fumonisin B1, Ghana

INTRODUCTION

Mycotoxins (aflatoxin and fumonisin) are toxic secondary metabolites produced by certain fungi in agricultural products that are susceptible to mould infestation. Mycotoxin contamination is difficult to predict, which makes it a challenge to food safety (Park and Stoloff, 1989). Aflatoxin (AFB1 being the most toxic) is produced on various food crops including maize, beans and groundnuts by Aspergillus flavus and Aspergillus parasiticus. Fumonisin B1 being the most toxic, is produced primarily in maize by Fusarium verticillioides and Fusarium moniliforme (Martins et al., 2001; Voss and Haschek, 2007). Environmental conditions such as high temperature, humidity, poor soil fertility, drought, insect damage, as well as the food production chains are characteristics in most parts of Africa where diets primarily consist of maize which is susceptible to fungal growth and mycotoxins production (Lewis et al., 2005).

Contamination of food products by mycotoxins can take place at any point along the food/feed chain from the field, harvest, handling, shipment and storage under a wide range of climatic conditions (Giray et al., 2007). Aflatoxin poisoning is one of the most common and most under-reported causes of toxicoses in poultry (Pattison et al., 2007). Aflatoxicosis in poultry and farm animals also causes changes in biochemical and hematological parameters, liver and kidney abnormalities, impaired immunity, and may induce mortality among animals, secondary contamination of human consumers via eggs, meat and milk (Shashidhara and Devegowda, 2003). Fumonisin (FB1) also suppresses the immune system, causes deficiency in nutrients such as folic acid (Blom et al., 2006) and the modification of sphingomyelin metabolism (Stockmann-Juva and Savolainen, 2008).

Research conducted in Nigeria, Tanzania and India on animal feed commodities showed mycotoxin contamination (Kehinde et al., 2014). Kajuna et al. (2013) in a study involving poultry feed in Tanzania reported that, 68% of all feed samples were contaminated with aflatoxin B1. In Haryana, India, poultry feed samples analysed by Jindal et al. (1999) contained fumonisin B1 contamination.

According to FAO report (2013), the rate of population growth over the past five decades has increased globally and has led to the rapid growth in the meat sector by rising demand of poultry meat, which has increased...
by threefold. The poultry industry has been a contributing area in agriculture that leads the economy with 34.5% share of the total growth domestic product in Ghana (Attuahene et al., 2012). Poisoning of poultry feed with mycotoxin could affect the total growth per domestic product of economy growth if not well investigated. Globally, maize (corn) and soybean are used in the preparation of poultry feed (Ensminger et al., 1990). Studies in Ghana have demonstrated contamination of weanmix food (a cereal-legume blend food) with aflatoxin and fumonisin (Kumi et al., 2014). Since a large number of poultry feed are prepared from these cereals, there is the possibility of mycotoxins contamination of poultry feed from Ghana. However, studies regarding aflatoxin and fumonisin levels in poultry feed in the animal industry are readily not available in Ghana.

Thus, the aim of the study was to investigate the levels of total aflatoxin (B1, B2, G1 and G2) and fumonisin B1 in poultry feed produced in Ghana.

MATERIALS AND METHODS

Study sites

Four major poultry producing regions in Ghana, which include Brong Ahafo, Ashanti, Accra and Western regions of Ghana, were selected for this study. The Brong Ahafo region is the largest poultry producing region which contributes to about 29.62% of poultry production followed by, 28.07%, 10.72% and 9.99% from Ashanti, Eastern and Western regions of Ghana respectively (FAO, 2014).

Sample collection

The poultry feed samples, which were made up of a blend of maize, wheat grain and wheat bran were collected from farmers who produced their own feed locally in Ghana. One hundred poultry farms were selected randomly for the study. Forty samples were collected from Accra, 20 from Ashanti, 21 from Western and 19 from Brong Ahafo regions of Ghana. Hundred grams of poultry feed samples, which were made up of layer mash, broiler starter, and grower mash were collected into sterile zip-locked bags and transported at room temperature to the Noguchi Memorial Institute for Medical Research. All laboratory work was conducted at the Noguchi Memorial Institute for Medical Research, University of Ghana.

Aflatoxin measurement

Sample preparation. About 50g of poultry feed was measured and blended with 5g sodium chloride (NaCl) and 100mls of 80% methanol in a blender at high speed for 1-2 minutes. The supernatant was collected and filtered twice using a filter paper. The filtered supernatant (10 mL) was measured into a clean vessel, diluted with 40mL of distilled water. Diluted extract was filtered twice through glass microfibre filter into a clean vessel.

Affinity chromatography. The diluted extract, 5 mL was passed through Afla Test affinity column at a rate of about 1-2 drops/second. The column was washed with 10 mL of distilled water. The extracted aflatoxin in the poultry feed was eluted with 1.0 mL HPLC grade methanol into a clean test tube.

Total aflatoxin quantification. Total aflatoxin quantification was done using a calibrated high-performance liquid chromatography with fluorescence detection of wavelength 365nm excitation and 425nm emission.

Fumonisin measurement

Sample extraction. Poultry feed sample (50g) and 5g sodium chloride (NaCl) were measured and blended with 100 mL of 80% methanol in a blender for 1-2 minutes. The supernatant was collected and filtered twice using a filter paper and diluted 4-fold with 0.1% Tween-20.

Affinity chromatography. Five (5 mL) of filtered diluted extract was passed through fumonitest affinity column at a rate of about 1-2 drops/second followed by 10 mL wash with distilled water. Fumonisin in the feed was eluted by passing 1.0 mL HPLC grade of methanol through column at a rate of 1-2 drops/second while collecting the entire sample eluted in a test tube.

Fumonisin quantification. Fumonisin developer (1.0 mL) was added to the eluted sample, mixed and read at a fluorescence detection of 483nm after 240 seconds using a calibrated fluorometer (VICAM, series 4) with detection limit 0.2 ppm (2 mg/kg).

Statistical analyses

All statistical analyses were performed using Sigma Stat (2012). The data obtained from measurement of mycotoxins (total aflatoxin and fumonisin B1) from the four regions of Ghana (Accra, Ashanti, Western and Brong Ahafo) were represented by tables and figures and subjected to simple descriptive statistics, which looked at the range and the mean.
RESULTS

Total aflatoxin (B1, B2, G1 and G2) and fumonisins B1 standard calibration curves were established with an $R^2 = 0.9913$ and 0.9887 respectively (Figures 1 and 2) to determine the linearity of the HPLC system. Out of 100 samples collected, total aflatoxin contamination were detected in all samples in a range of 0.02-22 ppb. Three samples representing 3% of the total samples collected were detected to have total aflatoxin levels greater than 20 ppb (Table 1). Fumonisin contamination was detected in all 100 samples in the range of 0.5-4.6 ppm (Table 2). There was no statistical significant differences in occurrence of mycotoxins (total aflatoxin and fumonisin B1) from the various regions with $P=0.530$ and 0.612 for aflatoxin and fumonisin respectively ($p$ significant was set to $<0.05$ with 95 percent confident level). Out of the 100 questionnaire analyses, 70 of the poultry feed samples collected, representing Greater Accra Region, Ashanti Region, Western Region, and Brong Ahafo Region had their feed mixed with antifungal binder to prevent fungal contamination whiles 30% did not use antifungal binders (Figure 3).

![Figure 2 - Standard curve of Fumonisin B1, at fluorescence 483nm](image2)

![Figure 3 - Pie chart showing the percentage of poultry feed samples with and without antifungal binders](image3)
The poultry industry has been a contributing area in agriculture which leads the economy with 34.5% share of the total growth domestic product (GDP) in Ghana (Attuahene et al., 2012). Occurrence of mycotoxins in poultry feed and feed ingredients are of worldwide concern since they reduce poultry performance and could be important vehicles for introducing aflatoxins residues into the human diet (Ardic et al., 2008). Consequently, many countries have regulated the maximum permissible levels of aflatoxin in food and feed products to reduce the hazard of aflatoxin poisoning but in terms of its economic considerations; these regulations vary in different countries (Stoloff et al., 1991).

Mycotoxins (total aflatoxin and fumonisin B1) were detected in all poultry feed samples analysed. The United States Food and Drug Administration, regulatory affairs and center for veterinary medicine guidelines for aflatoxin regulate the limit of aflatoxin levels in poultry feed as 20µg/kg (US FDA, 2019). According to the results of the present study, 97 feed samples representing 97% were below the permissible aflatoxin level of 20µg/kg in poultry feed. Three feed samples representing 3% recorded total aflatoxin levels above the permissible level of (Table 1). The three feed samples which were above the permissible aflatoxin levels were from samples, received from farmers who did not add fungal binders to their feed (Figure 3). Similar to the findings of the present study, another study conducted in Iran reported low aflatoxin levels ranged between 0.05 and 5.38µg/kg detected in 75 Iranian poultry feed samples (Mayahi et al., 2007). Aflatoxin B1 contamination was also found in sorghum and maize from India in the range 5-125 and 0.38-109 µg/kg respectively which constitute the major ingredients of poultry feed (Shetty and Bhati, 1997).

The presence of mycotoxin in poultry feed could results from the feed ingredients and raw materials used in their production (Lozada, 1995). Several mycotoxin binders have been developed that prevent harmful effects of mycotoxins on animals consuming contaminated feed. In a study conducted by Kolosova and Stroka (2012), commercial aflatoxin binders containing hydrated sodium calcium aluminosilicate was used as the main component in animal feed and showed a significant effect of 41% reduction on the amount of aflatoxin analysed. Seventy percent of the poultry feed obtained from farmers in the present study included fungal binders to their feed (Figure 3). The low levels of aflatoxin recorded in the present study could be due to the addition of fungal binders to poultry feed.

Maize and maize-based products were found to have the highest occurrence and mean concentrations of fumonisin B1 than any other cereal or cereal-based product in an evaluation by the Joint FAO/WHO Expert Committee meeting on Food Additives in 2016 in Rome, higher mean concentrations of fumonisin B1 was reported in products from Africa, Central and South America and some countries in the Western Pacific Region. In a study by Shetty and Bhat (1997), fumonisin B1 contamination in poultry feed were determined in the range of 0.02 to 0.26mg/kg. The present study reported fumonisin contamination in poultry feed in the range of 0.8-4.6 mg/kg (Table 2) which was lower than the permissible limit of 50 mg/kg set by the United States Food and Drug Administration (US FDA, 2001). The present study concurs to the report by Shetty and Bhat (1997) who reported similar findings. The low levels of fumonisin in poultry feed detected in the present study could be due to the fact...
that, majority of farmers who treated their feed with fungal binders (Figure 3). Majority of the poultry feed samples analysed had low levels of total aflatoxin and fumonisin B1.

CONCLUSION AND RECOMMENDATIONS

In accordance with the findings of the present study, it can be concluded that, most of the poultry feed samples collected and analyzed were within the permissible limit of total aflatoxin and fumonisin B1 consumption by poultry birds. Fungal binders were found to be helpful in reducing the amount of aflatoxin and fumonisin levels in poultry feed. Poultry farmers are encouraged to include antifungal binders to their feed before consumption by poultry birds. The present study for the first time in Ghana, probably has demonstrate the levels and the need to monitor poultry feed for mycotoxin contamination. However not withstanding farmers need to be educated on the dangers of mycotoxin poisoning to their birds.

DECLARATIONS
