Abstract Using the WKB approximation we analyse the tunnelling of a pulsating string in deformed Minkowski spacetime.

1 Introduction

There is a huge body of evidence that the AdS/CFT correspondence holds true for strings in $\text{AdS}_5 \times S^5$ and $\mathcal{N} = 4$ super Yang–Mills theory in four dimensions. For instance, the energy of spinning and rotating strings matches the anomalous dimension of operators in the gauge theory in the range where they can be compared. Integrability on both sides of the correspondence also provides further support for the correspondence [1]. It is also important to test the correspondence in situations with less supersymmetry where the gauge theories have deformed potentials leading to marginally deformed $\mathcal{N} = 2$ or $\mathcal{N} = 1$ supersymmetric gauge theories [2,3]. The gravitational dual of such theories has a deformed five-sphere characterised by a real parameter $\gamma$ and the dilaton and some RR and NS-NS fields are also present [4]. In this situation both sides of the correspondence also have integrable structures [5]. Spinning and rotating strings have also been considered in such a deformed context and they confirm the correspondence whenever they can be compared [5–16].

There is a class of string configurations, pulsating strings, which has not received much attention since its dual operator is not completely understood. They have been analysed in $\text{AdS}_5 \times S^5$ [17–27], $\text{AdS}_4 \times CP^3$ [28,29] and other backgrounds [30–37], and more recently they have been studied in the deformed case as well [38]. Since the string presents a periodic motion its dynamics can be characterised by its oscillation number. It is not one of the string charges but it is quite useful to parametrise its behaviour [23,38,39]. At the quantum level it is an adiabatic invariant so it provides information as regards the semi-classical regime for higher values of the oscillation number. In [38] we analysed pulsating strings in deformed Minkowski spacetime and in deformed $\text{AdS}_4 \times S^5$ for a small deformation. We have found the classical energy in terms of the oscillation number in the high and low energy limits. For high energy we performed the quantisation of the highly excited string states to second order in perturbation theory and found that the oscillation number has to be even. In the low energy case we found a new term, proportional to $\gamma$, which is not present in the classical case.

In order to analyse the classical dynamics of the pulsating string we introduced an effective potential which captures all relevant information as regards the deformed background. When the string pulsates on the deformed five-sphere its effective potential grows smoothly as one of the angles increase from zero to $\pi/2$ and the oscillation number can be expressed in terms of complete elliptic integrals [38]. In the case of deformed Minkowski spacetime the string pulsates along the radial direction and the effective potential starts growing from the origin until it reaches a maximum value of $m^2/(2\gamma)$ at $r^2 = 1/\gamma$ and then goes back to zero far away from the origin (see Fig. 1). It is clear that at low energies or small deformation the string has a periodic motion that can be quantised perturbatively as done in [38]. However, since the potential has a maximum, it is possible for the string to tunnel through the potential barrier and the computation of the transition rate for such a process is the main goal of this paper.

A non-perturbative phenomenon like tunnelling may be studied semi-classically using the WKB approximation whenever the amplitude or the phase of the wave function is taken to be slowly changing. The WKB method has been applied in several situation involving strings [40–44] and here it will be used to analyse the behaviour of a pulsating string in deformed Minkowski spacetime.

This paper is organised as follows. In Sect. 2 the pulsating string in deformed ten-dimensional Minkowski spacetime will be briefly described. In Sect. 3 we will use the WKB

\textsuperscript{a} e-mail: p12@ubi.pt
\textsuperscript{b} e-mail: rivelles@fma.if.usp.br
technique to calculate the transition rate for the pulsating string to tunnel through the potential. In Sect. 4 we will analyse the classical stability of the pulsating string and show that for small deformation it is stable. We then present some conclusions in the last section.

2 Pulsating strings in deformed Minkowski spacetime

The energy of a semi-classical pulsating string in ten-dimensional Minkowski spacetime and in $AdS_5 \times S^5$ was computed in terms of its oscillation number in [19] while for the case of a deformed Minkowski spacetime and deformed $AdS_5 \times S^5$ the energy was found in [38]. We will briefly review the case of deformed Minkowski spacetime. Lunin and Maldacena [4] found a technique to build deformed supergravity backgrounds which have a $U(1) \times U(1)$ global symmetry required by the deformed gauge theory. When applied to the ten-dimensional Minkowski spacetime it gives the deformed background

$$\text{dx}^2 = \eta_{\mu \nu} \text{d}x^\mu \text{d}x^\nu + \sum_{i=1}^{3} \left(\text{d} \tau_i^2 + \sqrt{\gamma} r_i^2 \text{d}\phi_i^2 \right) + \sqrt{\gamma} \sum_{i=1}^{3} r_i^2 \text{d}\phi_i^2,$$

where a four-dimensional Minkowski spacetime is left undeformed and the remaining six-dimensional space with coordinates $(r_i, \phi_i), i = 1, 2, 3,$ has a deformation parameter $\gamma$. When $\gamma$ vanishes we recover the ten-dimensional Minkowski spacetime. The dilaton and the $B_2$ field have non-trivial configurations given by

$$B_2 = \gamma G(r_1^2 r_2^2 \text{d}\phi_1 \wedge \text{d}\phi_2 + r_1^2 r_3^2 \text{d}\phi_3 \wedge \text{d}\phi_2 + r_2^2 r_3^2 \text{d}\phi_1 \wedge \text{d}\phi_3),$$

e^{2\Phi} = G.$$

The deformed Minkowski background is a supergravity solution [4], but only its bosonic part is known. The fermionic part is not relevant for our purposes. The parametrisation for a pulsating string used in [38] is not convenient in analysing stability issues. Instead we will take a string at the origin of Minkowski spacetime with

$$t = \sqrt{2} \kappa \tau, \quad r_1 = r_2 = r(\tau), \quad r_3 = 0, \quad \phi_1 = \phi_2 = m \sigma, \quad \phi_3 = 0,$$

where $m$ is the string winding number. This ansatz is compatible with the classical equations of motion for the pulsating string and is suitable for the classical stability analysis of Sect. 4. It corresponds to a string dynamically equivalent to the simplest and well-known pulsating strings studied in [19,38]. Using (2) in (1) we get

$$\text{ds}^2 = -\text{d}t^2 + \text{d}r^2 + G r^2 \text{d}\phi^2,$$

$$G^{-1} = 1 + \gamma r^2.$$

For this choice there is no coupling of the string to the $B_2$ field. Then the Nambu–Goto action becomes

$$S = -m \int \text{d}\tau r \sqrt{G} (1 - \dot{r}^2),$$

where we set the string tension equal to one.

We can then find that the radial canonical momentum $\Pi$ and the squared canonical Hamiltonian is given by

$$H^2 = \Pi^2 + \frac{m^2}{1 + \gamma r^2}.$$

We can identify an effective potential

$$V^2(r) = \frac{m^2 r^2}{1 + \gamma r^2},$$

which governs the string dynamics. The potential has a maximum at $r = 1/\sqrt{\gamma}$ where its value is $m^2/(2\gamma)$ (see Fig. 1) providing a barrier for a pulsating string trapped in the region $r < 1/\sqrt{\gamma}$. For a particle of energy $E^2 < m^2/(2\gamma)$ there are two points where its radial velocity vanishes

$$R_{1,2}^2 = \frac{m^2}{2\gamma^2 E^2} \left(1 + \sqrt{1 - \frac{4\gamma^2 E^4}{m^4}} \right).$$

This means that the pulsating string can, in principle, tunnel from $r < R_1$, through the classically forbidden region of the potential, and escape to the classically allowed region $r > R_2$.  

![Fig. 1](image-url)
The equation of motion can be integrated in terms of elliptic functions and the energy can be found in terms of the oscillation number \( N = \int \Pi dr/2\pi \). For more details see [38].

3 String tunnelling

To apply the WKB method we assume that the wave function depends only on \( r \) so that we can take for \( \Pi^2 \) the radial part of the Laplacian

\[
\Pi^2 = -\frac{\hbar^2}{\sqrt{-g}} \frac{d}{dr} \left( \sqrt{-g} \frac{d}{dr} \right),
\]

where \( \sqrt{-g} = r^{(d-1)}G \) is the determinant of the metric. Here we left the number of dimensions of the deformed part of the space \( d \) arbitrary since we want to consider the general situation. For the full ten-dimensional case \( d = 6 \). Then the Schrödinger equation reads

\[
-\frac{\hbar^2}{r^{(d-1)}} \left( r^{(d-1)} \Psi' \right) + \frac{4\hbar^2 r^2}{1 + \gamma^2 r^4} \Psi + \frac{m^2 r^2}{1 + \gamma^2 r^4} \Psi = E^2 \Psi,
\]

and the WKB ansatz is

\[
\Psi_{WKB}(r) = \begin{cases} 
A e^{\frac{j}{\hbar} \int_{R_1}^{r} \frac{d}{dr} P(r)} + B e^{-\frac{j}{\hbar} \int_{R_1}^{r} \frac{d}{dr} P(r)}, & r < R_1, \\
C e^{\frac{j}{\hbar} \int_{R_1}^{r} \frac{d}{dr} |P(r)|} + D e^{-\frac{j}{\hbar} \int_{R_1}^{r} \frac{d}{dr} |P(r)|}, & R_1 < r < R_2, \\
F e^{\frac{j}{\hbar} \int_{R_2}^{r} \frac{d}{dr} P(r)}, & r > R_2,
\end{cases}
\]

where \( A, B, C, D \) and \( F \) are constants and \( P(r) = \sqrt{E^2 - V^2(r)} \).

The WKB approximation does not hold in the neighbourhood of \( r = R_1 \) and \( r = R_2 \) because \( P(r) \) vanishes at these points. To avoid this problem we will consider solutions of (10) around these two points. To this end we introduce coordinates \( x = c_i(r - R_i) \), \( i = 1, 2 \), where \( R_i \) stands for \( R_1 \) or \( R_2 \), and we find that (10) reduces to

\[
\Psi''_{R_i} + i \frac{d}{r} \Psi_{R_i} - x \Psi_{R_i} = 0,
\]

where \( \Psi_{R_i} \) is the wave function around \( R_i \) and

\[
a_i = \frac{d - 5}{c_i R_i} \left( 1 + \frac{4}{d - 5 m^2 R_i^2} \right).
\]

If we choose

\[
c_i = \sqrt{\frac{2E^2 - 1 - \gamma^2 R_i^4}{\hbar^2 R_i + 1 + \gamma^2 R_i^4}},
\]

we can reduce (12) to the Airy equation by the change of variable \( \Psi_{R_i}(x) = \exp(-a_i x/2) \chi_i(x) \), which yields

\[
\chi_i''(x) - \left( x + \frac{a_i^2}{4} \right) \chi_i(x) = 0.
\]

Then, near \( R_1 \) and \( R_2 \), we have

\[
\Psi_{R_i}(x) = e^{-\frac{a_i x}{2}} \left( a_i Ai \left( x + \frac{a_i^2}{4} \right) + b_i Bi \left( x + \frac{a_i^2}{4} \right) \right),
\]

where \( a_i \) and \( b_i \) are integration constants and \( Ai(x) \) and \( Bi(x) \) are the two linearly independent Airy functions.

To match the WKB and the Airy solutions around \( R_i \) we must make sure that they have the same functional form for large \( |x| \). Around \( R_1 \) we find that in the WKB solution \( \int_{R_1}^{r} p(r) dr = 2/3\hbar (x - \gamma) \) for \( x < 0 \), while for \( x > 0 \), \( \int_{r}^{R_1} p(r) dr = -2/3\hbar x \). The Airy functions go like \( e^{\pm 2/3 (x - \gamma)^{3/2}} \) for \( x < 0 \) and \( \cos(2/3 (x - \gamma)^{3/2} - \pi/4) \) and \( \sin(2/3 (x - \gamma)^{3/2} - \pi/4) \) for \( x > 0 \). Similar expressions hold for the solutions around \( R_2 \). Matching the solutions we find that around \( R_1 \) we have

\[
a_1 = 2 \left( 1 + \gamma^2 R_1^4 \right)^{1/2} D, \]

\[
b_1 = \left( 1 + \gamma^2 R_1^4 \right)^{1/2} C, \]

\[
A = \left( -i D + \frac{C}{2} \right) e^{i\pi/4}, \]

\[
B = \left( i D + \frac{C}{2} \right) e^{-i\pi/4}, \]

\[
A_i = \left( 1 + \gamma^2 R_i^4 \right)^{1/2} D, \]

\[
b_i = \left( 1 + \gamma^2 R_i^4 \right)^{1/2} C, \]

\[
A = \left( -i D + \frac{C}{2} \right) e^{i\pi/4}, \]

\[
B = \left( i D + \frac{C}{2} \right) e^{-i\pi/4}, \]

\[
A_i = \left( 1 + \gamma^2 R_i^4 \right)^{1/2} D, \]

\[
b_i = \left( 1 + \gamma^2 R_i^4 \right)^{1/2} C, \]

\[
A = \left( -i D + \frac{C}{2} \right) e^{i\pi/4}, \]

\[
B = \left( i D + \frac{C}{2} \right) e^{-i\pi/4}, \]

\[
A_i = \left( 1 + \gamma^2 R_i^4 \right)^{1/2} D, \]

\[
b_i = \left( 1 + \gamma^2 R_i^4 \right)^{1/2} C, \]

\[
A = \left( -i D + \frac{C}{2} \right) e^{i\pi/4}, \]

\[
B = \left( i D + \frac{C}{2} \right) e^{-i\pi/4}, \]
while around $R_2$ we find

$$a_2 = 2 \left( 1 + \frac{\gamma^2 R_1^4}{\hbar c^2 R_2^{d-1}} \right)^{1/2} e^{\mathcal{P}/\hbar} C,$$

(21)

$$b_2 = \frac{1 + \gamma^2 R_4^4}{\hbar c^2 R_2^{d-1}} e^{-\mathcal{P}/\hbar} D,$$

(22)

$$a_2 = e^{i\pi/4} \left( 1 + \frac{\gamma^2 R_1^4}{\hbar c^2 R_2^{d-1}} \right)^{1/2} F,$$

(23)

$$b_2 = -ia_2,$$

(24)

where $\mathcal{P} = \int R_2 |p(r)| dr$. We can now compute $|F/A|^2$ to find

$$\left| \frac{F}{A} \right|^2 = \left( \frac{1}{4} e^{-P/\hbar} - e^{P/\hbar} \right)^2 = \frac{e^{-2\mathcal{P}/\hbar}}{\left( 1 - \frac{1}{4} e^{-2\mathcal{P}/\hbar} \right)^2}. \quad (25)$$

Notice that all explicit dependence on $d$ has gone away and only $\mathcal{P}$ depends on the dimension through the potential $V^2(r)$.

To find the tunnelling probability we have to consider the probability current $i(\Psi^* \nabla \Psi - \Psi \nabla \Psi^*)$ in the deformed Minkowski spacetime (1). Taking only the radial component and integrating it with the proper measure we find that the square root factors in (11) precisely cancel the measure factors so that in the region $r < R_1$ it gives $|B|^2 - |A|^2$. Unitarity is then respected since (17)–(24) imply that $|B|^2 - |A|^2 = |F|^2$. This means that the tunnelling amplitude $T = |F/A|^2$ is given by (25).

The tunnelling amplitude (25) depends only on $\mathcal{P} = \int R_2 |\sqrt{E^2 - V^2(r)}| dr$, with $V^2(r)$ given by (7). This integral is quite complicated but can be performed when the deformation is small. To that end we redefine $r$ as $\tilde{r} = \sqrt{\gamma} r$ so that for $\gamma << 1$ we have

$$\tilde{R}_1 = \sqrt{\gamma} R_1 = \sqrt{\frac{E}{m}} \left( 1 + \frac{1}{2} \gamma \frac{E^4}{m^4} \right), \quad (26)$$

$$\tilde{R}_2 = \sqrt{\gamma} R_2 = \frac{m}{\sqrt{E}} \left( 1 - \frac{1}{2} \gamma \frac{E^4}{m^4} \right). \quad (27)$$

Notice that $\tilde{R}_1 \tilde{R}_2 = 1$; from the condition $E^2 < m^2/(2\gamma)$ we find that $\tilde{R}_1 < 1$. Calling $\tilde{R} = \tilde{R}_1$, we find that

$$\tilde{P} = \frac{E}{\sqrt{\gamma R}} \int_{\tilde{R}}^{1/\tilde{R}} \sqrt{\frac{(1 - \tilde{R}^2 r^2)(\tilde{r}^2 - \tilde{R}^2)}{1 + \tilde{r}^4}} dr. \quad (28)$$

We can now split the integral from $\tilde{R}$ to $1/\tilde{R}$ into two integrals, one from $\tilde{R}$ to 1 and the other from 1 to $1/\tilde{R}$. For the second integral we can again change the integration variable $\tilde{r}$ to $1/\tilde{r}$ so that

$$\tilde{P} = \frac{E}{\sqrt{\gamma R}} \int_{1/\tilde{R}}^{1} \sqrt{\frac{(1 - \tilde{R}^2 r^2)(\tilde{r}^2 - \tilde{R}^2)}{1 + \tilde{r}^4}} \tilde{r} d\tilde{r}. \quad (29)$$

We can then expand the two factors in the numerator inside the square root and perform the integrals. Keeping only the leading terms in $\gamma$ we find that

$$\tilde{P} = \frac{m}{2\gamma} \left| \ln \left( \frac{\sqrt{\gamma} E}{m} \right) \right|, \quad (30)$$

so that when the deformation vanishes the transition amplitude also vanishes as expected.

### 4 Classical stability

As show in the previous section a pulsating string can tunnel through the potential barrier and this naturally raises questions about its classical stability. It is well known that spinning strings in anti-de Sitter spaces are classically unstable for large spin [45]. Pulsating strings, on the other hand, have better stability properties than spinning strings, as shown in [46]. In the following we will analyse the stability properties of pulsating strings in deformed Minkowski spacetime.

We start with the Polyakov action in curved spacetime regarding the string coordinates and the worldsheet metric as independent variables. Following [47] the first variation of the Polyakov action gives

$$\delta S_P = -\frac{\sqrt{\gamma}}{2} \int d\xi^2 \left[ \left( \frac{1}{2} h_{ab} G - G_{ab} \right) \delta h_{ab} - 2g_{\mu\nu} \left( \square X^\mu + h_{ab} \Gamma^\mu_{ab} X^a X^b \right) \delta X^\mu \right]. \quad (31)$$

where $G_{ab} = g_{\mu\nu} X^\mu_a X^\nu_b$ is the induced metric, $G = h_{ab} G_{ab}$ and $\Gamma^\mu_{ab}$ are the worldsheet coordinates. In order to get the second variation of the action, a general perturbation $\delta X^\mu$ is decomposed into normal and tangential components on the worldsheet as

$$\delta X^\mu = X^\mu_n \delta X^a + n^\mu_a \delta X^r, \quad r = 2, \ldots, 9, \quad (32)$$

where $\delta X^a$ is the tangential perturbation and $\delta X^r$ is the normal variation. The normal vectors $n^\mu_a$ are orthonormal to each other and obey

$$g_{\mu\nu} n^\mu_a n^\nu_b = \delta_{ab}, \quad g_{\mu\nu} X^\mu_a n^\nu_r = 0. \quad (33)$$

The non-physical perturbations are then excluded by the choice $\delta X^a = 0$. We now introduce the second fundamental
The equation of motion for the perturbation is then given by

\[ \Omega_{ab} = g_{\mu\nu} n^\mu_a \nabla_a X^\nu_b, \]

and the normal fundamental form \( \mu_{ras} \) defined, respectively, as

\[ \mu_{ras} = g_{\mu\nu} n^\mu_r \nabla_a n^\nu_s, \]

where \( \nabla_a = X^a \partial_a \), with \( \partial_a \) being the spacetime covariant derivative. After these definitions the second variation of the action is found to be

\[
\delta^2 S_P = -\frac{\sqrt\kappa}{2} \int d^2 \sqrt{-h} \left[ \delta h_{ab} \left( 2G^{bc}h^{ad} - \frac{1}{2} h^{ad} G^{bc} - \frac{1}{2} h^{ab} G^{cd} \right) \delta h_{cd} ight. \\
\left. + 2 \delta h_{ab} \delta_{ab} h_{cd} \frac{\partial}{\partial \Omega_{cd}} \delta h_{cd} \\
- 2 \delta h_{ab} \left( \delta \Omega_{3ab} \delta_{ab} - 2 h^{ab} \mu_{ras} \nabla_a \nabla_b \right) \\
- h^{ab} X^a_{ra} X^b_{rb} R_{\mu\kappa\lambda\nu} n^\kappa_r n^\lambda_s \right] \delta X^a, 
\]

where \( R_{\mu\kappa\lambda\nu} \) is the Riemann tensor. Taking into account that the variation of the internal metric is related to the variation of the spacetime coordinates by

\[ \Omega_{ab} \delta X^a = -\frac{1}{4}(G\delta h_{ab} - h_{ab} G_{cd} \delta h_{cd}), \]

it can be shown that the second variation of the action is

\[
\delta^2 S_P = -\frac{\lambda}{2} \int d^2 \sqrt{-h} \delta X^a \left( \delta \Omega_{3ab} - 2 h^{ab} \mu_{ras} \nabla_a \nabla_b \right) \\
- h^{ab} X^a_{ra} X^b_{rb} R_{\mu\kappa\lambda\nu} n^\kappa_r n^\lambda_s \delta X^a. 
\]

The equation of motion for the perturbation is then given by

\[
\Box X^a - 2 h^{ab} \mu_{ras} \partial_b X^a - h^{ab} \Omega_{3ab} \delta X^a \\
- \left( \delta \Omega_{3ab} \delta_{ab} + \frac{2}{G} h^{ac} h^{bd} \delta \Omega_{abcd} \right) \\
+ h^{ab} X^a_{ra} X^b_{rb} R_{\mu\kappa\lambda\nu} n^\kappa_r n^\lambda_s \delta X^a = 0. 
\]

Now we will particularise the stability analysis to the deformed Minkowski space \((1)\) using \((2)\). The equation of motion for \( r(\tau) \) is

\[ r(\tau) = \frac{k}{m} \left( 1 + \frac{1}{2} \gamma^2 \frac{k^4}{m^4} \sin \left( m \tau + \gamma^2 \frac{k^4}{m^4} g(\tau) \right) \right), \]

\[ g(\tau) = \frac{15}{16} \frac{\sin(2m\tau)}{4} - \frac{1}{64} \sin(4m\tau), \]

but they will not be needed for the stability analysis.

The induced metric is given by \( G_{00} = -G_{11} = -2m^2 r^2 G \) and the orthogonality of the normal basis \((33)\) requires

\[ \sqrt{2}\kappa n^\mu_r - (n^\mu_r + n^\mu_s) \partial_r = 0, \]

\[ n^\mu_r + n^\mu_s = 0. \]

The choice of the normal vectors satisfying the first constraint in \((41)\) requires some work. So let us denote our basis vectors

\[ n^\mu_r = (n^\mu_r, n^\mu_s, n^\mu_r, n^\mu_s), \]

which are chosen to be non-trivial for \( r = 2, 3 \). Using the constraint and the orthogonality condition, we obtain

\[ (1 - \alpha^2) n^\mu_3 + (1 - \alpha^2) n^\mu_3 - \alpha^2 n^\mu_3 = 0, \]

where \( \alpha = \frac{\sqrt{2} \kappa}{\sqrt{1 - 2\alpha} \kappa} \leq 1 \). The constraint also allows us to rewrite the normalisation as

\[ (1 - \alpha^2) n^\mu_3 + (1 - \alpha^2) n^\mu_3 = 1. \]

Matching the norm of the vectors and using \((44)\), we obtain

\[ n^\mu_3 = \pm \left( 1 - \alpha^2 \right) n^\mu_3 - \alpha^2 n^\mu_3. \]

By setting \( n^\mu_3 = -n^\mu_3 = \frac{1}{\sqrt{2}} \), we finally find

\[
\begin{align*}
\kappa_2 &= \frac{\kappa}{m r \sqrt{2}} \left( \frac{\sqrt{2}}{\kappa}, 0, 0, 0, 0, 0 \right), \\
\kappa_3 &= \left( 0, 0, 0, 0, \frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}, 0, 0, 0, 0 \right), \\
\kappa_4 &= \left( 0, 1, 0, 0, 0, 0, 0, 0, 0, 0 \right), \\
\kappa_5 &= \left( 0, 0, 0, 0, 0, 0, 0, 0, 0, 0 \right), \\
\kappa_6 &= \left( 0, 0, 0, 0, 0, 0, 0, 0, 0, 0 \right), \\
\kappa_7 &= \left( 0, 0, 0, 0, 0, 0, 0, 0, 0, 0 \right), \\
\kappa_8 &= \left( 0, 0, 0, 0, 0, 0, 0, 0, 0, 0 \right), \end{align*}
\]

For a small deformation, \( \gamma^2 \ll 1 \), it reduces to \( r^2 = \kappa^2 - m^2 r^2 + \gamma^2 m^2 X^2 \). Then the motion is periodic with amplitude \( \frac{1}{m} \left( 1 + \frac{1}{2} \gamma^2 \frac{k^4}{m^4} \right) \). We can find explicit solutions like...
Its second variation gives
\[\delta^2 \left( B_{\mu \nu} \epsilon^{ab} X^{\mu}_{a} X_{b}^{\nu} \right) = 2 \gamma m^2 G^3 (3 - 5r^4 \gamma^2) \dot{\delta} X^{r_1} + \delta X^{r_2} \times \left( \delta X^{\phi_2} - \delta X^{\phi_1} \right).\]

Using
\[\left( \delta X^{r_1} + \delta X^{r_2} \right) \left( \delta X^{\phi_2} - \delta X^{\phi_1} \right) = \left( n_{\phi_1}^2 + n_{\phi_2}^2 \right) \delta X_2 + \left( n_{\phi_1}^2 + n_{\phi_2}^2 \right) \delta X_3 \left( n_{\phi_1}^2 - n_{\phi_2}^2 \right) \delta X_8,\]

we find the final form for the equations of motion for the perturbations
\[\left( \square - \frac{1}{2r^2} + \gamma^2 r^2 G (1 - 6G) \right) \delta X_3 = 0,\]
\[\left( \square - \frac{5 \kappa^2 (1 - 2G)^2}{4m^2} - \gamma^2 \frac{\kappa^2}{m^2} (1 - 6G) \right) \times \dot{\delta} X_2 + 4 \gamma \kappa \dot{r} G (8G - 5) \delta X_8 = 0,\]
\[\left( \square - \frac{1}{2r^2} \right) \times \delta X_8 + 4 \gamma \kappa \dot{r} G (8G - 5) \delta X_2 = 0,\]
\[\square \delta X_r = 0, \quad r = 4, 5, 6, 7, 9.\]

Equation (58) shows that for \(r = 4, 5, 6, 7\) and 9 the perturbations are stable so that we have to consider only \(r = 2, 3\) and 8.

From now on we will analyse the stability for a small deformation \(\gamma \ll 1\). Keeping only the leading terms in \(\gamma\) the equations for the perturbations reduce to
\[\left( \square - \frac{1}{2r^2} - 5 \gamma^2 r^2 \right) \delta X_3 = 0,\]
\[\left( \square - \frac{5 \kappa^2}{4m^2} \frac{1}{r^2} \right) \delta X_2 + 12 \gamma \kappa \dot{r} \delta X_8 = 0,\]
\[\left( \square - \frac{1}{2r^2} \right) \delta X_8 + 12 \gamma \kappa \dot{r} \delta X_2 = 0.\]

We can now expand \(\delta X_i\) as
\[\delta X_i = \sum_{n=-\infty}^{\infty} e^{in\sigma} F_i(r),\]
and use \(\square = \frac{1}{2mr^2} (-\dot{\sigma}^2 + \dot{\delta}^2)\) to get
\[\left( \frac{d^2}{d\tau^2} + n^2 + m^2 + 10 \gamma^2 m^2 r^4 \right) F_3 = 0,\]
\[\left( \frac{d^2}{d\tau^2} + n^2 + \frac{5 \kappa^2}{2} \frac{1}{r^2} \right) F_2 - 24 \gamma \kappa m^2 r^2 \dot{r} F_8 = 0,\]
\[\left( \frac{d^2}{d\tau^2} + n^2 + m^2 \right) F_8 - 24 \gamma \kappa m^2 r^2 \dot{r} F_2 = 0.\]

In these equations \(r\) is the unperturbed solution to (39) which is a periodic function of \(\tau\). Then, by the Sturm theorem, \(F_3\) oscillates for large \(\tau\) so that the perturbation \(\delta X_3\) is stable. We can handle \(F_2\) and \(F_8\) by expanding in \(\gamma\) as \(F_2 = U_2 + \gamma V_2\).
some solutions of (63)–(69) in graphical form. To this end we need to consider a pulsating string solution of (39) in flat spacetime. As shown in [38] the condition to have an oscillatory motion is $2\gamma\kappa^2 \leq m^2$ and a solution of (39) in flat spacetime can be taken as $r(\tau) = \frac{\kappa}{m} \cos m\tau$. Using this solution in (63) we plot the mode $F_3$ in Figs. 2, 3 and 4. In these figures, we have for the deformation $\gamma = 1/2, 1/5$ and 1/10, while all other parameters, the winding number $m$, the mode $n$ of the perturbation and the stringy energy $\kappa$, are fixed. In these cases the perturbation amplitude modulates and is stable.

We now turn our attention to (66). Since $r(\tau)$ is periodic the term in $1/r^2$ diverges whenever $r$ vanishes and could cast doubts about the stability. In fact, when plotting $U_2$ we get warnings that there is some problem at $\tau = \pi/(2m)$. The same sort of problem appears in (64) and (65) or in (68) and (69). Our previous arguments, however, show that there is nothing special in those points. Since (66) is an ordinary differential equation we can solve it. Changing variables to $y = \sec^2(m\tau)$ and taking $U_2(y) = \gamma \frac{dy}{dc} G(y)$ we find that $G(y)$ satisfies the hypergeometrical differential equation so that

\[
U_2(\tau) = \sec^{n/2m}(m\tau) \sum F_1 \left( \frac{a}{2m}, \frac{a^*}{2m}; \sec^2(m\tau) \right),
\]

\[
a = \frac{n}{2m} + \frac{1}{4} \pm \frac{3}{4}i, \quad c = \frac{n}{m} + 1.
\]
theory corresponding to the deformed Minkowski spacetime is not known. Since the string tunnelling represents an instability of the system it would be very interesting to see what happens on the other side of the correspondence.
