Diphyllolobothriosis is an emerging zoonotic disease caused by broad fish tapeworms. Except for the Pacific broad tapeworm (Adenocephalus pacificus), whose life cycle is completed in the sea, all species of the genus Dibothriocephalus (formerly in Diphyllobothrium) were limited to the freshwaters in the Northern Hemisphere (1). However, some of these tapeworms also were reported in the Southern Hemisphere, including South America, especially Patagonia, in the 20th century. Although the introduction routes of these human parasites remain unknown, their larvae (plerocercoids) have appeared in South America in nonnative but economically important salmonids, such as rainbow, brown, and brook trout (2,3).

Several cases of diphyllolobothriosis have been reported from South America, and plerocercoids of tapeworms identified as Dibothriocephalus latus and D. dendriticus have been reported in fish (Appendix Table 1, https://wwwnc.cdc.gov/EID/article/25/11/19-0792-App1.pdf). However, species identification was based almost exclusively on morphologic characteristics. Considering general uniformity, inraspecific variability, and shortage of species-specific morphologic traits (especially in plerocercoids), all previous reports of D. latus and D. dendriticus tapeworms from South America need verification (4). Reports concerning the most commercially important species of salmonids being infected with D. latus tapeworms are especially dubious because this species most likely uses only freshwater perchid, esocid, and gadid fish as its second intermediate hosts in the Northern Hemisphere (1,4).

Reliable identification of plerocercoids, which are the source of diphyllolobothriosis, is crucial from the epidemiologic point of view because salmonids are of great economic value in South America as a food source for local populations, sport fishing, and exportation (5). We provide molecular evidence of second intermediate or paratenic host switching of human-infecting D. latus tapeworms in Patagonia, South America.

We found a total of 44 plerocercoids in 3 salmonid species: from Lake Gutiérrez, Rio Negro, Argentina (October 2017), rainbow trout (Oncorhynchus mykiss), of which 2/7 fish examined were infected; brown trout (Salmo trutta), of which 3/4 were infected; and brook trout (Salvelinus fontinalis), of which 5/10 were infected; and from Lake Alicura, Neuquén, Argentina (April 2018), brown trout, of which 3/4 were infected. Most plerocercoids were encysted in the body cavity, mainly among the pyloric ceca, and only a few were free in the muscle. We selected, photographed, and sequenced the partial cox1 gene of 22 larvae in accordance with the procedure described by Wicht et al. (6). We also photodocumented morphologic vouchers (hologenophores) of sequenced specimens (Figure).

Our morphologic and molecular evaluation revealed the presence of D. dendriticus plerocercoids in 12 fish (8...
in *O. mykiss* rainbow trout, 2 in *S. trutta* brown trout, and 2 in *S. fontinalis* brook trout); their sequences were identical with those of *D. dendriticus* tapeworms from Chile (GenBank accession nos. AB623150 and AB623149). We also detected the presence of *D. latus* plerocercoids in 10 fish (1 in *O. mykiss* rainbow trout, 3 in *S. trutta* brown trout, and 6 in *S. fontinalis* brook trout); these sequences were identical with those of *D. latus* tapeworms from Italy (GenBank accession no GU997614) (Appendix Table 2).

*D. dendriticus* plerocercoids have been reported in >50 species of freshwater fish of 12 families, and salmonids represent the principal, most common fish hosts (7). In contrast, *D. latus* plerocercoids have never been confirmed reliably in salmonids in the Northern Hemisphere, where they occur in relatively few freshwater fish species, such as perch (*Perca* spp.), pike (*Esox* spp.), ruffe (*Gymnocephalus cernua*), burbot (*Lota lota*), and walleye (*Sander* spp.) (4), which are not present in South America. Therefore, *D. latus* tapeworms had to adapt to new second or paratenic intermediate hosts (i.e., salmonids) after their introduction to the Southern Hemisphere, even though salmonids are not suitable hosts in the Northern Hemisphere, where these tapeworms occurred originally (1,4).

The origin of freshwater, human-infecting broad fish tapeworms in South America remains unknown. Salmonids were introduced to Chile (from Germany) and Argentina (from the United States) at the beginning of the 20th century as eggs or juveniles from a hatchery (8,9). However, no evidence indicates that naturally infected salmonids were imported to South America. Introduction of adult tapeworms of *Dibothriocephalus* spp. through infected humans or dogs cannot be ruled out, nor can the introduction of *D. dendriticus* tapeworms by migratory birds (1,4).

Our findings provide evidence of host switching of *D. latus* plerocercoids in Patagonia. Adaptation to new fish hosts might have serious epidemiologic consequences because of the economic importance of salmonids and their consumption by humans locally and abroad. Moreover, these introduced salmonids currently represent a substantial proportion of the total fish population in most of the lakes in the Andes region (5,10). Therefore, parasitologic examination of fish before their exportation on ice is necessary to avoid emergence of new foci of human diphyllobothriosis.

Achromobacter xylosoxidans Infections after Prostate Biopsies, France, 2014

DOI: https://doi.org/10.3201/eid2511.161487

To the Editor: We read with interest the article by Haviari et al. concerning a health care–associated outbreak of Achromobacter xylosoxidans infections after prostate biopsies (1). Although noteworthy, the description lacks some data.

First, the isolates of Achromobacter cannot be referred to as A. xylosoxidans from just the method used in this study, API 20 NE mass spectrometry (bioMérieux, https://www.biomerieux.com). Since 2012, a total of 18 species have been defined in the genus Achromobacter (2). Only multilocus sequence typing or sequencing 765 bp of the housekeeping gene nrdA enables the identification of the isolates to the species level (3). To date, in the few studies available, a great variety of species have been detected in clinical samples, with A. xylosoxidans the most predominant (4,5). Correct identification of the isolates involved in all types of infection is necessary to help understand the epidemiology, pathogenicity, and resistance pattern of the various species.

Second, the antimicrobial drug resistance profiles are not given (except for ceftriaxone, which is an intrinsic resistance, and ofloxacin) but again are valuable epidemiologic data. This information might help in detecting the emergence of new cases in the unit or in other hospitals, as well as in discussing the therapeutic options.

Finally, all the bacteria recovered in the container belonged to environmental waterborne genera frequently encountered in wet sites in hospitals. As discussed by the authors, these microorganisms have been involved in contamination of antiseptic solutions containing quaternary ammonium compounds or chlorhexidine. Unfortunately, the authors did not mention which disinfectants were used in the biopsy room (for hands, sinks, surfaces, or containers).
Host-Switching of Zoonotic Broad Fish Tapeworm (*Dibothriocephalus latus*) to Salmonids, Patagonia

Appendix

**Appendix Table 1.** Second intermediate or paratenic hosts of *D. dendriticus* (*Dd*) and *D. latus* (*Dl*) reported from South America (Argentinean and Chilean Patagonia)*

| Intermediate or paratenic hosts | *Dendriticus* | *D. latus* |
|--------------------------------|---------------|-----------|
| **1. Basilichthys australis** (Atherinopsidae) | – *Dd* (2), Chile; *Dl* (3), Chile | |
| **2. Diplomystes camposensis** (Diplomystidae) | – *Dd* (4), Chile | |
| **3. Galaxias maculatus** (Galaxiidae) | – *Dd* (5), Chile & *Dl* (2), Chile | |
| **4. Galaxias platei** (Galaxiidae) | – *Dl* (2), Chile | |
| **5. Odontesthes mauleanum** (Atherinopsidae) | – *Dd* (6), Chile | |
| **6. Oncorhynchus kisutch** (Salmonidae) | – *Dd* (7), cited as *D. microcordiceps*, Argentina & *Dl* (8), Chile | |
| **7. Percilia gillissi** (Perciliidae) | – *Dd* (2), Chile | |
| **8. *Salmo salar*** (Salmonidae) | – *Dd* (7), Argentina | |
| **9. *Salmo trutta*** (Salmonidae) | – *Dd* (9), Argentina | |
| **10. *Salvelinus fontinalis*** (Salmonidae) | *Dd* & *Dl* (7), Argentina | |

* Asterisks indicate introduced hosts. More recent data available at Rauque et al. (1).

**Appendix Table 2.** Sequenced samples of plerocercoids from Argentina. Results based on PCR amplification using species-specific primers for partial *cox1* mt gene and consequent sequential analysis.
