Abstract

Background Aspirin exerts side effects within the gastrointestinal tract. Hydrogen sulfide (H₂S) and carbon monoxide (CO) have been implicated in gastroprotection but the mechanism of beneficial action of these gaseous mediators against aspirin-induced damage has not been fully studied. We determined the involvement of afferent sensory neurons, calcitonin-gene-related peptide (CGRP), lipid peroxidation, and nitric oxide (NO) biosynthesis in gastroprotection of H₂S-releasing NaHS and CO-releasing tricarbonyldichlororuthenium(II) dimer (CORM-2) against aspirin-induced injury.

Methods Wistar rats with or without capsaicin-induced denervation of sensory neurons were pretreated with vehicle, CORM-2 (5 mg/kg intragastrically), or NaHS (5 mg/kg intragastrically) with or without capsazepine (5 mg/kg intragastrically) or N(G)-nitro-L-arginine (L-NNA, 20 mg/kg intraperitoneally). The areas of aspirin-induced lesions and gastric blood flow (GBF) were assessed by planimetry and laser flowmetry respectively. Gastric mucosal messenger RNA and/or protein expression of CGRP, heme oxygenase 1, inducible nitric oxide synthase, cyclooxygenase 2, interleukin-1β, glutathione peroxidase 1 (GPx-1), and superoxide dismutase was determined by real-time PCR or Western blot. Malondialdehyde (MDA) and 4-hydroxynonenal (4-HNE) content was determined by colorimetric assay.

Results Aspirin caused gastric lesions, decreased GBF, and raised MDA content, but pretreatment with NaHS and CORM-2 reduced these effects. Capsaicin-induced denervation or co-treatment with capsazepine reversed the gastroprotective and vasodilatory effects of NaHS but not those of CORM-2. L-NNA reversed NaHS-induced gastroprotection and partly reduced CORM-2-induced gastroprotection. NaHS and CORM-2 decreased MDA and 4-HNE content, restoring GPx-1 protein expression.

Conclusions We conclude that H₂S- but not CO-mediated gastroprotection against aspirin-induced injury involves afferent sensory nerves and partly NO activity. NaHS and CORM-2 prevented aspirin-induced gastric mucosal lipid peroxidation via restoration of microcirculation and antioxidative GPx-1 protein expression.

Keywords Hydrogen sulfide · Carbon monoxide · Nitric oxide · Afferent sensory nerves · Aspirin

Introduction

Aspirin is the most popular representative among the nonsteroidal anti-inflammatory drugs (NSAIDs), which, however, exerts side effects within the gastrointestinal tract, including hemorrhagic microbleedings and gastric erosions [1–4]. The gaseous mediators hydrogen sulfide (H₂S), carbon monoxide (CO), and nitric oxide (NO) were reported to afford gastroprotection against injury induced by noxious agents but the mechanism of this beneficial action of these molecules has not been fully elucidated [5–10]. All three mediators have been shown to take part in
regulation of physiological processes in the gastrointestinal tract and other systems [11–13]. The H2S-releasing derivatives of NSAIDs, such as ATB-346, exert an anti-inflammatory effect similar to that of the parent drugs (naproxen in the case of ATB-346) but cause pronouncedly fewer side effects as compared with the native form of the drug. This indicates the usefulness of this new class of H2S derivatives of NSAIDs and the potential safety and possible translation to clinical settings [14]. Moreover, these recently introduced NSAID prodrugs—namely, H2S-releasing anti-inflammatory drugs—were suggested as promising agents in chemoprevention of cancers [15, 16]. Recently, it has been reported that inhibition of H2S generation contributes to the formation of aspirin-induced gastric injury [5]. The CO and H2S biosynthesis pathways were both shown to synergistically interact in the mechanism of gastroprotection against NSAID-induced gastric damage via restoration of gastric microcirculation impaired by these drugs [17].

We aimed to investigate the involvement of afferent sensory neurons, calcitonin-gene-related peptide (CGRP), and vanilloid receptor 1 (also known as transient receptor potential cation channel V1; TRPV1) in gastroprotection of H2S released from NaHS and CO released from tricarbonyldichlororuthenium(II) dimer (CORM-2) and the accompanying changes in gastric blood flow (GBF) with regard to experimental gastric lesions induced by aspirin. Moreover, we studied the potential role of H2S and CO in regulation of aspirin-induced lipid peroxidation. We also investigated the involvement of endogenous NO and messenger RNA (mRNA) or protein expression of the antioxidant enzymes glutathione peroxidase 1 (GPx-1) and superoxide dismutase (SOD) in the protective activity of H2S and CO against aspirin-induced ulcerogenesis.

Materials and methods

Animals, chemicals and drugs, and determination of the gastric damage and GBF

Seventy male Wistar rats weighting 220–300 g were fasted for 24 h with free access to drinking water before the experiments. The study was approved by the Institutional Animal Care and Use Committee of Jagiellonian University Medical College in Cracow and was conducted in accordance with the Helsinki Declaration regarding handling of experimental animals.

Two weeks before the experiment, capsaicin was administered subcutaneously to some of the rats (series A) in three doses of 25, 50, and 50 mg/kg (total dose 125 mg/kg) to induce the functional ablation of sensory nerves as reported in our previous studies [18, 19].

On the day of experiment, aspirin dissolved in 0.2 M HCl solution was administered intragastrically in a dose of 125 mg/kg (1.5 ml per rat) to induce gastric lesions, as described previously [17]. Thirty minutes before aspirin application, rats with capsaicin-induced denervation (series A) and rats without capsaicin-induced denervation (series B) were pretreated intragastrically with (1) 0.9% saline (vehicle control) or dimethyl sulfoxide and saline (1:10), (2) CO-releasing CORM-2 [20], applied in a dose of 5 mg/kg, which has previously been reported by our group to increase CO content in gastric mucosa and to exert gastroprotection against aspirin- and ethanol-induced gastric damage [17, 21], or (3) NaHS, the H2S-releasing salt applied intragastrically in a dose of 5 mg/kg, which has been demonstrated to protect gastric mucosa against aspirin-, stress-, or alendronate-induced lesions [17, 19, 22]. In a separate series (C), rats with intact sensory nerves were pretreated with NaHS or CORM-2 in combination with capsazepine (5 mg/kg intragastrically), a TRPV1 antagonist [23], or N^ω-nitro-L-arginine (L-NNA, 20 mg/kg intraperitoneally), a nonselective nitric oxide synthase (NOS) inhibitor [24]. All chemicals were purchased from Sigma-Aldrich (Schnelldorf, Germany) and were injected intraperitoneally or administered intragastrically by means of an orogastric tube as reported previously [18, 25].

One hour after administration of aspirin, rats were anesthetized with pentobarbital (60 mg/kg intraperitoneally). Their abdomens were opened for the GBF measurement by a laser Doppler flowmeter (Laserflo blood perfusion monitor, model BPM 403A, Vasamedics, St Paul, MN, USA), as described elsewhere [25]. The stomach was excised and opened along the greater curvature to determine the area of aspirin-induced gastric lesions by means of computerized planimetry (Morphomat, Carl Zeiss, Berlin, Germany) [26, 27]. Next, the gastric mucosal samples from oxyntic mucosa were scraped off on ice, snap-frozen in liquid nitrogen, and stored at −80 °C until further analysis [21].

Determination of mRNA expression of β-actin, α-CGRP, heme oxygenase 1, cyclooxygenase 2, inducible NOS, interleukin-1β, GPx-1, and SOD-2 in rat gastric mucosa by real-time polymerase chain reaction

Expression of mRNA for particular genes of interest in gastric mucosa was determined by real-time polymerase chain reaction (PCR) as described previously [21, 22]. Briefly, RNA was isolated from gastric mucosal biopsy samples with use of a GeneMATRIX universal RNA
purification kit (EURx, Gdansk, Poland). Reverse transcrip-
tion to complementary DNA was performed with a
high-capacity complementary DNA reverse transcription
kit (Thermo Fisher Scientific, Life Technologies, MA,
USA). Expression of β-actin, heme oxygenase 1 (HO-1),
cyclooxygenase (COX)-2, inducible NOS (iNOS), inter-
leukin-1β (IL-1β), GPx-1, and SOD-2 was determined by
real-time PCR using specific primers [17, 22]. SG qPCR
master mix (2×) including SYBR Green (EURx, Gdansk,
Poland), and Quant Studio 12K Flex thermal cycler
(Thermo Fisher Scientific, MA, USA). To determine α-
CGRP mRNA expression, 5′-GCTCACCAGGGAGG-
CATCAT-3′ forward primer and 5′-ATGCCTGGTA-
CAGGAGCAAGA-3′ reverse primer were used. β-Actin
was used as an internal control. Data were analyzed by the
2−ΔΔCt method [28].

Determination of protein expression in gastric
mucosa by Western blot

Protein expression of β-actin, GPx-1, SOD-1, and iNOS in
gastric mucosa was determined by Western blot, as
described previously [17, 21, 22]. Rabbit polyclonal anti-
iNOS antibody (1:500, ab3523, Abcam, Cambridge, UK),
rabbit polyclonal anti-GPx-1 antibody (1:1000, ab22604,
Abcam), rabbit polyclonal anti-SOD-1 antibody (1:1000,
ab13498, Abcam), and rabbit polyclonal anti-β-actin anti-
body (1:1000, 20536-1-AP, Proteintech, Manchester, UK)
were used as primary antibodies. Protein expression was
visualized by means of peroxidase-conjugated secondary
goat anti-rabbit IgG antibody (sc-2004, Santa Cruz
Biotechnology) at a dilution of 1:2000. All primary and
secondary antibodies were diluted in 5% nonfat milk.

Chemiluminescence was developed with use of
WesternSure™ enhanced chemiluminescence substrate (LI-
COR, Lincoln, NE, USA) and was measured with a
C-DiGit® blot scanner (LI-COR). The intensity of bands
was determined and analyzed by Image Studio 4.0 (LI-
COR). The expression of the proteins of interest was
normalized to the expression of β-actin as a loading control.

Determination of the gastric mucosal lipid
peroxidation as malondialdehyde and 4-
hydroxynonenal content

To determine malondialdehyde (MDA) and 4-hydroxy-
ynenal (4-HNE) tissue concentration, the colorimetric
assay for lipid peroxidation (Bioxxytech LPO-586, Oxis,
Portland, OR, USA) was used as described previously [27].
In brief, about 200 mg of gastric mucosa was excised and
then quickly washed in a test tube, and 20 μL 0.5 M buty-
lated hydroxytoluene was added to prevent sample oxida-
tion. Next, samples were homogenized in 20 mM
tris(hydroxymethyl)aminomethane for 15 s in pH 7.4 and
centrifuged (3000g at 4 °C for 10 min). The supernatant was
collected and stored at −80 °C until further analysis. The
colorimetric assay used to determine MDA concentration
in gastric mucosa is based on the reaction of a chromogenic
reagent (N-methyl-2-phenylindole) with MDA and 4-HNE
at 45 °C, which yields a stable chromophore with maximal
absorbance at 586 nm, analyzed with a microplate reader
(Tecan Sunrise, Männedorf, Switzerland).

Statistical analysis

The results are presented as the mean ± standard error of
the mean. Statistical analysis was performed with Student’s
t test or the Mann–Whitney U test if appropriate assump-
tions did not hold. ANOVA with the Tukey post hoc test
was used if more than two experimental groups were
compared. We considered p < 0.05 to be statistically sig-
nificant. Data were analyzed with GraphPad Prism 5.0.

Results

Effect of afferent sensory nerve ablation
and inhibition of TRPV1 receptors on CORM-2-
and NaHS-mediated gastroprotection

Figure 1 shows that pretreatment with CORM-2 (5 mg/kg
intragastrically) and NaHS (5 mg/kg intragastrically) sig-
nificantly decreased the mean area of gastric lesions and
significantly increased GBF as compared with vehicle
treatment (p < 0.05) (Fig. 1). These data confirm our
previously published results that CO and H2S donors pro-
tected gastric mucosa against aspirin-induced gastric
damage [17]. Capsaicin-induced denervation significantly
increased the area of aspirin-induced gastric lesions and
decreased GBF as compared with vehicle treatment in rats
with intact sensory nerves (p < 0.05) (Fig. 1). The reduc-
tion of the area of gastric lesions and the accompanying
increase in GBF caused by NaHS were reversed in rats
with capsacin-induced denervation (p < 0.05) (Fig. 1).
Capsazepine (5 mg/kg intragastrically) by itself did not
affect aspirin-induced gastric damage and GBF as com-
pared with vehicle treatment (Fig. 1). When NaHS was
combined with capsazepine, a significant increase in the
mean area of gastric lesions as compared with that for rats
pretreated with this H2S donor alone was observed
(p < 0.05), whereas GBF was significantly increased as
compared with that in the vehicle-control group (p < 0.05).
The capsazepine and CORM-2 co-treatment failed to affect
the decrease of gastric damage area and the increase in
GBF as compared with the respective values obtained in
the group of rats pretreated with CORM-2 alone (Fig. 1).
Expression of CGRP mRNA in gastric mucosa

Figure 2 shows that the CGRP mRNA expression in gastric mucosa with aspirin-induced gastric damage was significantly increased in rats with capsaicin-induced denervation pretreated with vehicle as compared with the respective values in intact gastric mucosa and the vehicle-pretreated group without capsaicin-induced denervation (p < 0.05) (Fig. 2). Pretreatment with CORM-2 but not with NaHS significantly decreased mRNA expression of CGRP in gastric mucosa of rats with aspirin-induced gastric damage as compared with the vehicle-control group (p < 0.05) (Fig. 2).

Expression of HO-1, iNOS, COX-2, and IL-1β mRNA in gastric mucosa

Figure 3 shows that the mRNA expression for HO-1, iNOS, COX-2, or IL-1β was significantly increased in vehicle-pretreated gastric mucosa in rats administered with aspirin as compared with that observed in intact rats (p < 0.05). Pretreatment with CORM-2 significantly increased mRNA expression of HO-1 and significantly decreased mRNA expression of iNOS, COX-2, and IL-1β in rats with aspirin-induced gastric damage as compared with the vehicle-control group without capsaicin-induced denervation.
denervation (p < 0.05) (Fig. 3). The pretreatment with NaHS significantly decreased mRNA expression of IL-1β but not that of HO-1, iNOS, or COX-2 as compared with vehicle treatment without capsaicin-induced denervation (p < 0.05) (Fig. 3). These results confirmed our data published previously [17]. In vehicle-pretreated rats with capsaicin-induced denervation, mRNA expression of HO-1, iNOS, or IL-1β was significantly increased as compared with that in respective group without capsaicin denervation (p < 0.05) (Fig. 3a, b, d). In rats with afferent sensory nerves ablation, pretreatment with CORM-2 but not NaHS significantly decreased IL-1β mRNA expression as compared with that in the vehicle-treated control group (p < 0.05) (Fig. 3d). Pretreatment with CORM-2 or NaHS

Fig. 3 Messenger RNA (mRNA) expression of a heme oxygenase 1 (HO-1), b inducible nitric oxide synthase (iNOS), c cyclooxygenase 2 (COX-2), and d interleukin-1β (IL-1β) in gastric mucosa of rats with or without capsaicin-induced denervation and pretreated with vehicle, NaHS (5 mg/kg intragastrically), or tricarbonyldichlororuthenium(II) dimer (CORM-2; 5 mg/kg intragastrically) and 30 min later given aspirin (ASA; 125 mg/kg intragastrically). Intact refers to healthy rats without any treatment. The results are expressed as mRNA expression of HO-1 (a), iNOS (b), COX-2 (c), and IL-1β (d) normalized to β-actin expression and are the mean ± standard error of the mean of four or five determinations per group. One asterisk indicates a significant change as compared with the values in intact gastric mucosa (p < 0.05). A significant change as compared with the values obtained in the vehicle-pretreated group with intact sensory nerves is indicated by a cross or two asterisks (p < 0.05). A significant change as compared with the vehicle-control group with capsaicin-induced denervation is indicated by two crosses (p < 0.05). i.g. intragastrically
did not affect mRNA expression of HO-1, iNOS, or COX-2 in gastric mucosa of rats with sensory nerve ablation and given aspirin.

**Expression of GPx-1 and SOD-2 mRNA in gastric mucosa**

The results for gastric mucosal mRNA expression of GPx-1 and SOD-2 in intact rats and those with or without capsaicin-induced denervation pretreated with vehicle, CORM-2, or NaHS and exposed to aspirin are presented in Fig. 4. The expression of GPx-1 and SOD-2 mRNA was significantly decreased in vehicle-pretreated rats given aspirin as compared with intact rats ($p < 0.05$). Pretreatment with NaHS significantly increased GPx-1 and SOD-2 mRNA expression in gastric mucosa of rats with intact sensory nerves ($p < 0.05$) (Fig. 4). In rats with intact sensory nerves, the pretreatment with NaHS failed to affect GPx-1 or SOD-2 mRNA expression as compared with vehicle pretreatment combined with exposure to aspirin (Fig. 4). Likewise, in rats with capsaicin-induced denervation, the pretreatment with NaHS did not affect GPx-1 or SOD-2 mRNA expression as compared with vehicle pretreatment combined with exposure to aspirin but this mRNA expression for both antioxidizing enzymes was significantly decreased as compared with that in the group with intact sensory nerves and pretreated with NaHS ($p < 0.05$) (Fig. 4).

**Effect of NOS inhibition on CORM-2- and NaHS-mediated gastroprotection against aspirin-induced gastric damage**

Figure 5 shows that CORM-2 and NaHS administered in a dose of 5 mg/kg intragastrically significantly decreased the area of aspirin-induced gastric damage (Fig. 5a) and increased GBF (Fig. 5b) as compared with vehicle treatment ($p < 0.05$), and these results are similar to the data presented in Fig. 1. When CORM-2 was administered with L-NNA, the area of gastric lesions was significantly increased as compared with that in vehicle-pretreated rats receiving CORM-2 and compromised by aspirin (control) ($p < 0.05$) but the GBF was not significantly altered in these rats (Fig. 5). Concurrent administration of NaHS and L-NNA (20 mg/kg intraperitoneally) significantly increased the area of gastric lesions (Fig. 5a) and significantly decreased GBF (Fig. 5b) as compared with the values observed when this H$_2$S donor was applied without L-NNA ($p < 0.05$).
Protein expression of iNOS, SOD-1 and GPx-1 in gastric mucosa

Figure 6a shows that protein expression of iNOS is significantly increased in gastric mucosa compromised by aspirin as compared with intact gastric mucosa ($p < 0.05$). Pretreatment with CORM-2 (5 mg/kg intragastrically) or NaHS (5 mg/kg intragastrically) significantly increased protein expression of GPx-1 but not SOD-1 as compared with vehicle pretreatment ($p < 0.05$) (Fig. 6b, c).

Determination of MDA and 4-HNE content in gastric mucosa

MDA and 4-HNE content in gastric mucosa was significantly increased in rats pretreated with vehicle and given aspirin as compared with intact rats ($p < 0.05$) (Fig. 7). The pretreatment with CORM-2 (5 mg/kg intragastrically) or NaHS (5 mg/kg intragastrically) significantly decreased MDA and 4-HNE content in gastric mucosa compromised by aspirin as compared with vehicle pretreatment ($p < 0.05$).

Discussion

In this study we used an experimental model of acute aspirin-induced gastric damage, which resembles microbleeds and gastric erosions in human gastric mucosa. Previous studies have documented that the mechanism of aspirin-induced gastric damage involves an inhibition of cytoprotective prostaglandin E$_2$ production via COX-1/COX-2 enzymatic activity and the prominent fall in GBF leading to the formation of severe hemorrhagic lesions of gastric mucosa [5, 29–33]. On the other hand, recent studies reported that the endogenous gaseous mediators H$_2$S, CO, and NO contribute to the maintenance of gastric mucosal integrity and prevent the formation of gastric mucosal lesions induced by various noxious stimuli, such as exposure to stress or administration of ethanol, bisphosphonates, and NSAIDs, including aspirin [5, 17, 19, 21, 22, 26, 34].

We have observed that pretreatment with CORM-2 or NaHS, both applied in a dose of 5 mg/kg, protected gastric mucosa against aspirin-induced gastric damage and increased the GBF, which is similar to what our group presented elsewhere [17]. Herein, we have demonstrated for the first time that this beneficial protective effect of an H$_2$S donor but not that of a CO donor was reduced in rats with capsaicin-induced denervation, suggesting that the protective activity of NaHS releasing H$_2$S unlike CORM-2 releasing CO can be mediated by neuropeptides such as CGRP released from sensory afferent nerves. Moreover, we found that neither NaHS nor CORM-2 had any significant influence on the gastric mucosal expression of CGRP in rats without sensory innervation treated with aspirin. However, this expression of CGRP was dramatically upregulated in rats with capsaicin-induced afferent sensory
Fig. 6  Protein expression of a inducible nitric oxide synthase (iNOS), b superoxide dismutase 1 (SOD), and c glutathione peroxidase 1 (GPx) in gastric mucosa of rats pretreated with vehicle, NaHS (5 mg/kg intragastrically) or tricarbonyldichlororuthenium(II) dimer (CORM-2; 5 mg/kg intragastrically) and 30 min later given aspirin (ASA; 125 mg/kg intragastrically). Intact refers to healthy rats without any treatment. The results are expressed as protein expression of iNOS, SOD, or GPx normalized to β-actin expression and are the mean ± standard error of the mean for four or five rats per group. An asterisk indicates a significant change as compared with the values in intact gastric mucosa (p < 0.05). A cross indicates a significant change as compared with the values obtained in the vehicle-pretreated group (p < 0.05). i.g. intragastrically.
nerve denervation, and this effect was attenuated by pretreatment with CORM-2 but not NaHS. We studied whether the protection by H₂S against aspirin ulcerogenesis could be mediated by the NO–TRPV1–CGRP signaling pathway. Recently, the H₂S-evoked vasodilatory effects were attributed to NO production and activation of the HNO–transient receptor potential cation channel A1 (TRPA1)–CGRP pathway, indicating that these mediators can contribute to the enhancement in the gastric microcirculation observed in the present study [35]. When an H₂S donor was administered in combination with the TRPV1 antagonist capsazepine, the NaHS-induced protection was reversed. However, capsazepine did not affect the NaHS-induced increase in GBF, suggesting that in this model H₂S can regulate GBF with no involvement of TRPV1 receptors. On the other hand, capsazepine failed to influence the CORM-2-induced attenuation of aspirin damage and the accompanying rise in GBF. We observed that capsaicin-induced denervation even further enhanced the increase of mRNA expression of proinflammatory markers such as iNOS, IL-1β, COX-2, and HO-1 observed in rats subjected to aspirin. The expression of proinflammatory IL-1β mRNA was abrogated by CORM-2, and this effect was not influenced by capsaicin-induced denervation in contrast to groups pretreated with NaHS. However, neither a CO donor nor H₂S-releasing NaHS, decreased upregulated mRNA expression of HO-1, iNOS, or COX-2 in rats with sensory nerve ablation. On the basis of these findings, we assume that CO decreased infiltration of IL-1β-induced activation of neutrophils and macrophages in the gastric mucosa after administration of aspirin in rats with capsaicin-induced denervation. However, this gaseous mediator was not sufficiently effective in regulation of intracellular inflammation because it failed to affect an increase in iNOS, HO-1, and COX-2 mRNA expression in these rats with capsaicin-induced denervation. In contrast to rats with intact sensory nerves, the pretreatment with NaHS did not alter the mRNA expression of the antioxidative enzymes GPx-1 or SOD-2 in gastric mucosa compromised by aspirin, which was evidently suppressed in rats with capsaicin-induced denervation, confirming that H₂S-donor-mediated gastroprotection depends on afferent sensory nerve activity. The results of the present study corroborate with previously published evidence that NaHS-induced gastroprotection against stress-induced gastric mucosal lesions is attenuated in rats with functional ablation of afferent sensory nerves [19]. Therefore, we conclude that the gastroprotective effect of NaHS releasing H₂S against aspirin-induced lesions depends on the activity of afferent sensory neurons and CGRP, which is known to exert vasodilatory, anti-inflammatory, and antioxidative properties. However, sensory nerves releasing vasodilatory neuropeptides seem to be less important in CORM-2-induced gastroprotection because despite this CO donor reduced aspirin-induced damage, it failed to attenuate all molecular proinflammatory and antioxidative parameters overexpressed in rats with capsaicin-induced denervation. Our data suggest that H₂S-induced gastroprotection against aspirin-induced damage may involve endogenous NO biosynthesis since administration of a nonselective NO inhibitor, L-NNA, completely abolished the protective and hyperemic effects of NaHS in rats administered with aspirin. CO-mediated gastroprotection was only reduced when CORM-2 was combined with L-NNA. Moreover, the upregulation of gastric mucosal iNOS protein expression induced by aspirin was decreased in rats pretreated with CORM-2 but not with NaHS. This finding is in keeping with our previous observation that CO released from CORM-2 decreased NO content that was possibly elevated because of an increase in iNOS activity in gastric mucosa of rats compromised by stress and that L-NNA had no effect on the gastroprotective action of this compound [26]. Regarding the effect of L-NNA on NaHS-induced gastroprotection, there is convincing evidence that H₂S can interact with NO in the regulation of mucus secretion, GBF, and gastric mucosal defense in experimental models.
and in regulation of vascular tone in animals and humans [36, 37]. We cannot exclude the possibility that NO is involved in CORM-2-induced gastroprotection because an in vitro study revealed that CORM-2 directly enhanced endothelial NOS activity mediated by intracellular calcium release, intracellular Akt signaling, and endothelial NOS dimerization [38]. Therefore, we conclude that endogenous NO can mediate H2S gastroprotection against aspirin-induced damage and that this endogenous mediator can be, only in part, involved in CO-induced gastroprotection.

After administration of aspirin, lipid peroxidation was increased since the MDA and 4-HNE content in gastric mucosa reached higher concentrations than those recorded in healthy intact rats, whereas the protein expression and mRNA expression in gastric mucosa for the antioxidative enzymes GPx-1 and SOD were both decreased in aspirin-treated gastric mucosa. CORM-2 and NaHS prevented an aspirin-induced increase in gastric mucosal lipid peroxidation and restored protein expression of GPx-1 but not that of SOD-1. This effect could be explained by an aspirin-induced decrease in gastric mucosa of the availability of metals, which are known to be bound to SOD [39, 40]. Both CORM-2 and NaHS failed to reduce this effect of aspirin, because SOD protein expression remained decreased as observed 1 h after aspirin administration. We speculate that a longer time after aspirin administration than that used in our study is needed to observe the influence of NaHS and CORM-2 on aspirin-induced impairment in SOD protein expression. However, in contrast to CORM-2, pretreatment with NaHS increased mRNA expression for antioxidative SOD-2 in gastric mucosa compromised by aspirin. NaHS but not CORM-2 restored GPx-1 mRNA expression in gastric mucosa injured by aspirin. Together these observations suggest that mainly H2S but to lesser degree of CO can promote an antioxidative response in gastric mucosa at the mRNA level for both enzymes. It has previously been reported that differences in GPx-1 and SOD activities could serve as a marker of the pathological condition [41]. Our present observations support recent findings that H2S-releasing Lawesson’s reagent or another CO donor, dimanganese decacarbonyl, protected gastric mucosa against alendronate-induced gastric damage via regulation of oxidative stress as manifested by an increase in reduced glutathione content and a decrease in MDA content in rat gastric mucosa injured by alendronate [42, 43]. Thus, we conclude that the antioxidative properties of the gaseous mediators CO and H2S can contribute, at least in part, to the observed gastroprotective effect of these molecules against aspirin-induced gastric damage. CO seems to protect gastric mucosa against oxidation induced by aspirin, whereas additionally H2S stimulates an antioxidative gastric mucosal response at the molecular level.

From the findings taken together, we conclude that H2S-mediated gastroprotection against aspirin-induced mucosal lesions involves an increase in gastric microcirculation mediated by endogenous NO. However, a CO-mediated beneficial protective effect against aspirin-induced damage may depend only in part on NO biosynthesis. NaHS-induced gastroprotection unlike CORM-2-induced gastroprotection depends on the activity of afferent sensory nerves releasing CGRP and on the activation of TRPV1. Both H2S released from NaHS and CO released from CORM-2 attenuate the aspirin-induced rise in MDA content considered as an index of gastric mucosal lipid peroxidation and can improve the antioxidative status of gastric mucosa because of the restoration of antioxidative GPx-1 protein expression impaired by aspirin treatment.
