Abstract

We present the derivation of the hydrodynamic limit under Eulerian scaling for a general class of one-dimensional interacting particle systems with two or more conservation laws. Following Yau’s relative entropy method it turns out that in case of more than one conservation laws, in order that the system exhibit hydrodynamic behaviour, some particular identities reminiscent of Onsager’s reciprocity relations must hold. We check validity of these identities for a wide class of models. It also follows that, as a general rule, the equilibrium thermodynamic entropy (as function of the densities of the conserved variables) is a globally convex Lax entropy of the hyperbolic systems of conservation laws arising as hydrodynamic limit. The Onsager relations arising in this context and its consequences seem to be novel. As concrete examples we also present a number of models modeling deposition (or domain growth) phenomena.

1 Introduction

We investigate the hydrodynamic behaviour of a very general class of one dimensional interacting particle systems with two or more conserved observables. The systems are not reversible and the hydrodynamic limit under Eulerian scaling is investigated. We apply Yau’s relative entropy method and obtain validity of the hydrodynamic limit up to the occurrence of the first shock wave in the solution of the limiting pde. There is no novelty in the standard steps of the relative entropy proof, so we only sketch these. The real novelty appears when it turns out that, in case of more than one conserved quantity, in order to complete the relative entropy proof, a class of identities should hold, relating the macroscopic fluxes appearing in the
hydrodynamic pdes. These identities are much reminiscent of Onsager’s reciprocity relations. As far as we know these relations have not been pointed out in the context mathematically rigorous Eulerian hydrodynamics. We check the validity of these relations for the very general class of interacting particle systems considered. As a consequence of the Onsager relations it follows that the systems of partial differential equations (systems of conservation laws) arising as hydrodynamic limit are by force of hyperbolic type and the equilibrium thermodynamic entropy of the system (as function of the densities of the conserved quantities) is globally convex Lax entropy of the hydrodynamic equations. This fact may be not so surprising, as it is commonly accepted physical fact. So much so that hyperbolic systems of conservation laws possessing a globally convex Lax entropy are commonly called of physical type, see [9]. Nevertheless, as far as we know, this fact has not been emphasized in the context of mathematically rigorous derivation of hydrodynamic behaviour. It is worth noting that given a hyperbolic system of conservation laws the existence of convex Lax entropies is far from trivial: in the case of two component systems the local existence of convex Lax entropies was established in the very technical work [5]. In case of more than two components in general the pdes defining Lax entropies are overdetermined, so in general Lax entropies do not exist at all. It turns out from our result that the hyperbolic systems of conservation laws arising as hydrodynamic limit are of very special type: they always possess a globally convex Lax entropy, namely the equilibrium thermodynamic entropy of the system.

Beside the general framework we also present a number of concrete examples of deposition models with two conserved quantities to which the general result applies, deriving in this way systems of pdes (hyperbolic systems of conservation laws) which describe macroscopically domain growth phenomena in 1+1 dimension.

Our general results are easily extended to more than one dimensions, however the formalism becomes more complicated. We were mostly motivated by the (one dimensional) deposition models presented as concrete examples.

The paper is organized as follows: In section 3 we present the general formalism and the conditions under which the hydrodynamic limit is derived.
In section 3 we state the main results of the paper. In section 4 we present a number of concrete examples to which the general framework applies. We hope that the models introduced in this section could be of interest in the context of deposition/domain growth phenomena. In section 5 we sketch the proof of the main result formulated in section 3. The sketchy proof is broken up into several parts. We only hint at the standard steps of the relative entropy proof, referring the reader to the original work [13] or the monographs [4] or [3]. The essential parts of this section are subsections 5.2 and 5.3 where the Onsager relations and their consequences are derived. Finally, in section 6 we extend the results formulated in the previous sections from two to arbitrary number of conserved quantities.

2 Microscopic models

2.1 State space, conserved quantities

Throughout this paper we denote by $T^N$ the discrete tori $\mathbb{Z}/N\mathbb{Z}$, $N \in \mathbb{N}$, and by $T$ the continuous torus $\mathbb{R}/\mathbb{Z}$. We will denote the local spin state by $S$, we only consider the case when $S$ is finite. The state space of the interacting particle system is

$$\Omega^N := S^{T^N}.$$ 

Configurations will be denoted

$$\omega := (\omega_j)_{j \in T^N} \in \Omega^N,$$

For sake of simplicity we consider discrete (integer valued) conserved quantities only. The two conserved quantities are denoted by

$$\xi: S \to \mathbb{Z},$$
$$\eta: S \to \mathbb{Z},$$

we also use the notations $\xi_j = \xi(\omega_j)$, $\eta_j = \eta(\omega_j)$. This means that the sums $\sum_j \xi_j$ and $\sum_j \eta_j$ are conserved by the dynamics. We assume that the conserved quantities are different and non-trivial, i.e. the functions $\xi, \eta$ and the constant function 1 on $S$ are linearly independent.
2.2 Rate function, infinitesimal generator

We consider the rate function \( r : S \times S \times S \times S \to \mathbb{R}_+ \). The dynamics of the system consists of elementary jumps effecting nearest neighbour spins, \((\omega_j, \omega_{j+1}) \to (\omega'_j, \omega'_{j+1})\), performed with rate \( r(\omega_j, \omega_{j+1}; \omega'_j, \omega'_{j+1}) \).

We require that the rate function \( r \) satisfy the following conditions.

(A) If \( r(\omega_1, \omega_2; \omega'_1, \omega'_2) > 0 \) then
\[
\begin{align*}
\xi(\omega_1) + \xi(\omega_2) &= \xi(\omega'_1) + \xi(\omega'_2), \\
\eta(\omega_1) + \eta(\omega_2) &= \eta(\omega'_1) + \eta(\omega'_2).
\end{align*}
\]

(B) For every \( K \in [\min \xi, \max \xi], L \in [\min \eta, \max \eta] \) the set
\[
\Omega_{K,L}^N := \left\{ \omega \in \Omega^N : \sum_{j \in \mathbb{T}^N} \xi_j = K, \sum_{j \in \mathbb{T}^N} \eta_j = L \right\}
\]
is an irreducible component of \( \Omega^N \), i.e. if \( \omega, \omega' \in \Omega^N \) then there exists a series of elementary jumps with positive rates transforming \( \omega \) into \( \omega' \).

(C) There exists a probability measure \( \pi \) on \( S \) such that for any \( \omega_1, \omega_2, \omega'_1, \omega'_2 \in S \)
\[
\pi(\omega_1)\pi(\omega_2)r(\omega_1, \omega_2; \omega'_1, \omega'_2) = \pi(\omega'_2)\pi(\omega'_1)r(\omega'_2, \omega'_1; \omega_2, \omega_1).
\]

(D) We denote \( R(\omega_1, \omega_2) := \sum_{\omega'_1, \omega'_2 \in S} r(\omega_1, \omega_2; \omega'_1, \omega'_2) \). This is the total jump rate of the nearest neighbour spin pair \((\omega_1, \omega_2)\). Then for any \( \omega_1, \omega_2, \omega_3 \in S \)
\[
R(\omega_1, \omega_2) + R(\omega_2, \omega_3) + R(\omega_3, \omega_1) = R(\omega_1, \omega_3) + R(\omega_3, \omega_2) + R(\omega_2, \omega_1).
\]

For a precise formulation of the infinitesimal generator on \( \Omega^N \) we first define the map \( \Theta_j^{\omega', \omega''} : \Omega^N \to \Omega^N \) for every \( \omega', \omega'' \in S, j \in \mathbb{T}^N \):
\[
\left( \Theta_j^{\omega', \omega''}(\omega) \right)_i = \begin{cases} 
\omega' & \text{if } i = j \\
\omega'' & \text{if } i = j + 1 \\
\omega_1 & \text{if } i \neq j, j + 1.
\end{cases}
\]

The infinitesimal generator of the process defined on \( \Omega^N \) is
\[
L^N f(\omega) = \sum_{j \in \mathbb{T}^N} \sum_{\omega', \omega'' \in S} r(\omega_j, \omega_{j+1}; \omega', \omega'')(f(\Theta_j^{\omega', \omega''}(\omega)) - f(\omega)).
\]
We denote by $X_t^N$ the Markov process on the state space $\Omega^N$ with infinitesimal generator $L^N$.

**Remarks:**

1. Condition (A) implies that $\sum_j \xi_j$ and $\sum_j \eta_j$ are indeed conserved quantities of the dynamics, while condition (B) ensures that there are no other hidden conservation laws.

2. Condition (B) is somewhat implicit. It seems to us that it is far not trivial (if not impossible) to formulate explicit conditions involving the rate functions which would be necessary and sufficient for irreducibility. However, in the concrete examples treated in section 4 one can easily check that irreducibility holds.

3. Conditions (A), (B) and (C) determine the measure $\pi(\omega)$ up to an exponential distortion, that is the probability measures satisfying these conditions are of the form (2) of the next subsection.

4. Conditions (C) and (D) imply that the stationary measures of the process $X_t^N$ are computable and have the structure required for hydrodynamic behaviour. See the next subsection for details. Another consequence of these conditions is Lemma 1 which turns out to be of crucial importance for hydrodynamic behaviour.

### 2.3 Stationary measures, reversed process

For every $\theta, \tau \in \mathbb{R}$ let $G(\theta, \tau)$ be the moment generating function defined below:

$$G(\theta, \tau) := \log \sum_{\omega \in S} e^{\theta \xi(\omega) + \tau \eta(\omega)} \pi(\omega).$$

In thermodynamic terms $G(\theta, \tau)$ corresponds to the Gibbs free energy, see 7. We define the probability measures

$$\pi_{\theta, \tau}(\omega) := \pi(\omega) \exp(\theta \xi(\omega) + \tau \eta(\omega) - G(\theta, \tau))$$

(2)

on $S$. 

5
Using conditions (C) and (D), by very similar considerations as in [1], [2], [8] or [12] one can show that for any \( \theta \) and \( \tau \) the product measure

\[
\pi^N_{\theta, \tau} := \prod_{j \in \mathbb{T}^N} \pi_{\theta, \tau}
\]

is stationary for the Markov process on \( X^N_t \) on \( \Omega^N \) with infinitesimal generator \( L^N \). We will refer to these measures as the canonical measures. Since \( \sum_j \xi_j \) and \( \sum_j \eta_j \) are conserved the canonical measures on \( \Omega^N \) are not ergodic. The conditioned measures defined on \( \Omega^N_{K,L} \) by:

\[
\pi^N_{K,L}(\omega) := \pi^N_{\theta, \tau}\left(\omega \mid \sum_j \xi_j = K, \sum_j \eta_j = L\right) = \frac{\pi^N_{\theta, \tau}(\omega) \mathbb{1}\{\omega \in \Omega^N_{K,L}\}}{\pi^N_{\theta, \tau}(\Omega^N_{K,L})}
\]

are also stationary and due to condition (B) satisfied by the rate functions they are also ergodic. We shall call these measures the microcanonical measures of our system. (It is easy to see that the measure \( \pi^N_{K,L} \) does not depend on the values of \( \theta, \tau \).)

The elementary movements of the reversed stationary process are \((\omega_{j-1}, \omega_j) \rightarrow (\omega'_{j-1}, \omega'_j)\) with rate \( r(\omega_j, \omega_{j-1}; \omega'_j, \omega'_{j-1}) \). The reversed generator is

\[
L^*_N f(\omega) = \sum_{j \in \mathbb{T}^N} \sum_{\omega', \omega'' \in S} r(\omega_j, \omega_{j-1}; \omega'', \omega')(f(\Theta_{j-1}^{\omega'} \omega'') - f(\omega)).
\]

This is the adjoint of the operator \( L^N \) with respect to all microcanonical (and canonical) measures. I.e. the reversed process is the same for any \( \pi^N_{\theta, \tau} \) or \( \pi^N_{K,L} \).

### 2.4 Expectations

Expectation, variance, covariance with respect to the measures \( \pi^N_{\theta, \tau} \) will be denoted by \( E_{\theta, \tau}(\cdot), \text{Var}_{\theta, \tau}(\cdot), \text{Cov}_{\theta, \tau}(\cdot) \).

We compute the expectations of the conserved quantities with respect to the canonical measures, as functions of the parameters \( \theta \) and \( \tau \):

\[
u(\theta, \tau) := E_{\theta, \tau}(\eta) = \sum_{\omega \in S} \eta(\omega) \pi_{\theta, \tau}(\omega) = G'_{\tau}(\theta, \tau),
\]

\[
u(\theta, \tau) := E_{\theta, \tau}(\xi) = \sum_{\omega \in S} \xi(\omega) \pi_{\theta, \tau}(\omega) = G'_{\theta}(\theta, \tau).
\]
Elementary calculations show, that the matrix-valued function
\[
\left( \begin{array}{cc}
u'_\theta & v'_\tau \\
\theta'_\theta & \theta'_\tau \end{array} \right) = \left( \begin{array}{cc}
G''_{\theta\theta} & G''_{\theta\tau} \\
G''_{\theta\tau} & G''_{\tau\tau} \end{array} \right) =: G''(\theta, \tau)
\]
is equal to the covariance matrix \( \text{Cov}_{\theta, \tau}(\xi, \eta) \) and therefore it is strictly positive definite. It follows that the function \((\theta, \tau) \mapsto (u(\theta, \tau), v(\theta, \tau))\) is invertible. We denote the inverse function by \((u, v) \mapsto (\theta(u, v), \tau(u, v))\). Actually, denoting by \((u, v) \mapsto S(u, v)\) the convex conjugate (Legendre transform) of the strictly convex function \((\theta, \tau) \mapsto G(\theta, \tau)\):
\[
S(u, v) := \sup_{\theta, \tau} (u\theta + v\tau - G(\theta, \tau)), \tag{3}
\]
we have
\[
\theta(u, v) = S'_u(u, v), \quad \tau(u, v) = S'_v(u, v).
\]
In probabilistic terms: \( S(u, v) \) is the rate function for joint large deviations of \( (\sum_j \xi_j, \sum_j \eta_j) \). In thermodynamic terms: \( S(u, v) \) corresponds to the equilibrium thermodynamic entropy, see [7]. Let
\[
\left( \begin{array}{cc}
\theta'_u & \theta'_v \\
\tau'_u & \tau'_v \end{array} \right) = \left( \begin{array}{cc}
S''_{uu} & S''_{uv} \\
S''_{uv} & S''_{vv} \end{array} \right) =: S''(u, v).
\]
It is obvious that the matrices \( G''(\theta, \tau) \) and \( S''(u, v) \) are strictly positive definite and are inverse of each other:
\[
G''(\theta, \tau)S''(u, v) = I, \tag{4}
\]
where either \((\theta, \tau) = (u(\theta, \tau), v(\theta, \tau))\) or \((u, v) = (\theta(u, v), \tau(u, v))\). With slight abuse of notation we shall denote: \( \pi_{\theta(u, v), \tau(u, v)} =: \pi_{u, v}, \pi^N_{\theta(u, v), \tau(u, v)} =: \pi^N_{u, v}, E_{\theta(u, v), \tau(u, v)} =: E_{u, v}, \) etc.

We introduce the flux of the conserved quantities. The infinitesimal generator \( L^N \) acts on the conserved quantities as follows:
\[
L^N_\xi_i = -\phi(\omega_i, \omega_{i+1}) + \phi(\omega_{i-1}, \omega_i) =: -\phi_i + \phi_{i-1}, \\
L^N_\eta_i = -\psi(\omega_i, \omega_{i+1}) + \psi(\omega_{i-1}, \omega_i) =: -\psi_i + \psi_{i-1},
\]
where

\[ \phi(\omega_1, \omega_2) := \sum_{\omega'_1, \omega'_2 \in S} r(\omega_1, \omega_2; \omega'_1, \omega'_2)(\xi(\omega'_2) - \xi(\omega_2)) \]

\[ = \sum_{\omega'_1, \omega'_2 \in S} r(\omega_1, \omega_2; \omega'_1, \omega'_2)(\xi(\omega_1) - \xi(\omega'_1)), \]

\[ \psi(\omega_1, \omega_2) := \sum_{\omega'_1, \omega'_2 \in S} r(\omega_1, \omega_2; \omega'_1, \omega'_2)(\eta(\omega'_2) - \eta(\omega_2)) \]

\[ = \sum_{\omega'_1, \omega'_2 \in S} r(\omega_1, \omega_2; \omega'_1, \omega'_2)(\eta(\omega_1) - \eta(\omega'_1)). \]

(5)

We shall denote the expectations of these functions with respect to the canonical measure \( \pi^2 \) by

\[ \Phi(u, v) := \mathbb{E}_{u,v}(\phi) \]

\[ = \sum_{\omega_1, \omega_2, \omega'_1, \omega'_2 \in S} r(\omega_1, \omega_2; \omega'_1, \omega'_2)(\xi(\omega'_2) - \xi(\omega_2))\pi_{u,v}(\omega_1)\pi_{u,v}(\omega_2), \]

(6)

\[ \Psi(u, v) := \mathbb{E}_{u,v}(\psi) \]

\[ = \sum_{\omega_1, \omega_2, \omega'_1, \omega'_2 \in S} r(\omega_1, \omega_2; \omega'_1, \omega'_2)(\eta(\omega'_2) - \eta(\omega_2))\pi_{u,v}(\omega_1)\pi_{u,v}(\omega_2). \]

The first derivative matrix of the fluxes \( \Phi \) and \( \Psi \) will be denoted

\[ D(u, v) := \begin{pmatrix} \Phi'_u & \Phi'_v \\ \Psi'_u & \Psi'_v \end{pmatrix} \]

(7)

As a general convention, if \( \delta : S^m \to \mathbb{R} \) is a local function then its expectation with respect to the canonical measure \( \pi^m \) is denoted by

\[ \Delta(u, v) := \mathbb{E}_{u,v}(\delta) = \sum_{\omega_1, \ldots, \omega_m \in S^m} \delta(\omega_1, \ldots, \omega_m)\pi_{u,v}(\omega_1)\cdots\pi_{u,v}(\omega_m). \]

3 The hydrodynamic limit

We will show, applying Yau’s relative entropy method, that under Eulerian scaling the local densities of the conserved quantities \( u(t, x) \), \( v(t, x) \) evolve according to the following system of partial differential equations:

\[ \begin{cases} \partial_t u + \partial_x \Phi(u, v) = 0 \\ \partial_t v + \partial_x \Psi(u, v) = 0 \end{cases} \]

(8)

It also turns out from our proof (more precisely as a consequence of the Onsager relations proved in Lemma 1) that the systems of conservation
laws (8) arising as hydrodynamic limits are necessarily of hyperbolic type and the equilibrium thermodynamic entropy function \((u, v) \mapsto S(u, v)\) is a (very special) globally convex Lax entropy for the system (8). (See [9] or [10] for the pde notions used.) This may be not so surprising, as it is commonly accepted fact and drops out automatically, without any computations in some particular model systems investigated so far. Nevertheless, we have not found a general statement or proof of this fact in the hydrodynamic limit literature.

3.1 Notations

For the proper formulation of our results we need some more notations. Let \(u(t, x), v(t, x), t \in [0, T], x \in S\) be a smooth solution of (8) (more precisely: let it be twice continuously differentiable in both variables). We shall use the notations

\[ \theta(t, x) := \theta(u(t, x), v(t, x)) \]
\[ \tau(t, x) := \tau(u(t, x), v(t, x)). \]

The true distribution of the Markov process \(X^N_s\) at macroscopic time \(t\), i.e., at microscopic time \(Nt\) is

\[ \mu^N_t := \mu^N_0 \exp \{ NtL^N \}. \]  

(9)

The true distribution will be compared to the following time dependent reference measure (also called local equilibrium) on \(\Omega^N\):

\[ \nu^N_t := \prod_{j \in T^N} \pi_{u(t, \frac{j}{N}), v(t, \frac{j}{N})}. \]  

(10)

This measure is not stationary (unless \(u\) and \(v\) are constant), and the local densities of the conserved quantities are discrete approximations of the functions \(u(t, x), v(t, x)\).

We shall use a stationary measure \(\pi^N := \pi^N_{0,0}\) on \(\Omega^N\) as an absolute reference measure. The Radon-Nikodym derivatives of the true distribution and the time dependent reference measure with respect to the absolute
reference measure are denoted as follows:

\[
\begin{align*}
    h_t^N &:= \frac{d\mu_t^N}{d\pi^N}(\omega) = \exp\{NtL^*N\}h_0^N, \\
    f_t^N &:= \frac{d\nu_t^N}{d\pi^N}(\omega) \\
    &= \prod_{j \in \mathbb{N}} \exp\{\xi(\omega_j)\theta(t, \frac{j}{N}) + \eta(\omega_j)\tau(t, \frac{j}{N}) - G(\theta(t, \frac{j}{N}), \tau(t, \frac{j}{N}))\}
\end{align*}
\]

3.2 The main result

Our aim is to prove that if \(\mu_0^N\) is close to \(\nu_0^N\) in the sense of relative entropy, then \(\mu_t^N\) stays close to \(\nu_t^N\) in the same sense uniformly for \(t \in [0, T]\). If we consider two different pairs of smooth solutions \((u_i(t,x), v_i(t,x))\), \(i = 1, 2\) of (8) it is a simple exercise to show that the relative entropy of the two time dependent reference measures is of order \(\asymp N\). This suggests that one should prove

\[
H^N(t) := H(\mu_t^N \mid \nu_t^N) = o(N),
\]

uniformly for \(t \in [0, T]\).

Theorem. Consider an interacting particles system model defined as in the previous section which satisfies conditions (A), (B), (C) and (D). Let \(\Phi(u, v)\) and \(\Psi(u, v)\) be defined as in (8).

(i) The system of conservation laws (8) is hyperbolic in the domain \((u, v) \in (\min \xi, \max \xi) \times (\min \eta, \max \eta)\). Furthermore, the equilibrium thermodynamic entropy \((u, v) \mapsto S(u, v)\) is a globally convex Lax entropy for the system (8).

(ii) Let \([0, T] \times \mathbb{T} \ni (t, x) \mapsto (u(t,x), v(t,x))\) be a smooth solution of (8), and let \(\mu_t^N\) and \(\nu_t^N\) be the measures defined in (9), respectively, (10). Then, if

\[
H(\mu_0^N \mid \pi^N) = O(N),
\]

and (12) holds for \(t = 0\) then it will hold uniformly for \(t \in [0, T]\).

Remark: Part (i) of the Theorem is commonly accepted fact. In some particular models investigated it simply drops out without any computation. However, we do not know about any explicit formulation (or proof) of the general fact stated here.
From part (ii) of the Theorem, by applying the entropy inequality in a standard way (comparing the true measure $\mu^N_t$ with the local equilibrium reference measure $\nu^N_t$) one gets the following corollary:

**Corollary.** Under the conditions of the Theorem, for any $t \in [0,T]$, the following limits hold as $N \to \infty$:

(i) For any smooth test function $g : T \to \mathbb{R}$
\[
\frac{1}{N} \sum_{j \in \mathbb{T}^N} g(j/N)\xi_j(t) \xrightarrow{P} \int_T g(x)u(t,x) \, dx,
\]
\[
\frac{1}{N} \sum_{j \in \mathbb{T}^N} g(j/N)\eta_j(t) \xrightarrow{P} \int_T g(x)v(t,x) \, dx.
\]

(ii) The asymptotics of the relative entropy of the true distribution $\mu^N_t$ with respect to the absolute reference measure $\pi^N_{u_0,v_0}$ is
\[
N^{-1}H(\mu^N_t \mid \pi^N_{u_0,v_0}) \to \int_T (S(u(t,x),v(t,x)) - S(u_0,v_0)) \, dx,
\]
where $S(u,v)$ is the thermodynamic entropy defined in (3).

**Remark:** Note that since $S(u,v)$ is Lax entropy of the pde (8) the right hand side of (13) does not change in time as long as the solution $(u(t,x),v(t,x))$ of (8) is smooth, and starts to decrease when the first shock appears. This means that the relative entropy $H(\mu^N_t \mid \pi^N_{u_0,v_0})$ decreases by $o(N)$ before the appearance of the first shock in the system.

### 4 Examples: deposition models

If we fix the size of the spin space, then we have finitely many equations from the conditions on the rate function, thus we can get a finite-parameter family of models. The smallest value of $|S|$, for which there exists a proper model is 3, since we need to have two different non-trivial conserved quantities.

We present two concrete examples: one with $|S| = 3$, one with $|S| = 4$. A third example with $|S| = \infty$, to which the Theorem applies with some modifications, is described in [11].

Our concrete examples are *deposition models*. $\eta : S \to \mathbb{N}$, and $\xi : S \to \mathbb{Z}$. $\eta_j$, respectively, $\xi_j$ are interpreted as particle occupation number, respectively, (negative) discrete gradient of deposition height. The dynamical
driving mechanism is such that
(i) The deposition height growth is influenced by the local particle density. Typically: growth is enhanced by higher particle densities.
(ii) The particle motion is itself influenced by the deposition profile. Typically: particles are pushed in the direction of the negative gradient of the deposition height.

It is natural to assume left-right symmetry of the models. This is realized in the following way. There is an involution
\[ R : S \rightarrow S, \quad R \circ R = Id \]
which acts on the conserved quantities and the jump rates as follows:
\[ \eta(R\omega) = \eta(\omega), \quad \xi(R\omega) = -\xi(\omega), \]
\[ r(R\omega_2, R\omega_1; R\omega'_2, R\omega'_1) = r(\omega_1, \omega_2; \omega'_1, \omega'_2). \quad (14) \]

Correspondingly on the macroscopic level we shall use the traditional notation \( \rho(t, x) \) (instead of \( v(t, x) \) of the general formulation) and \( u(t, x) \). The limiting partial differential equations will be also invariant under the left-right reflection symmetry: \( (\rho(t, x), u(t, x)) \mapsto (\rho(t, -x), -u(t, -x)) \).

### 4.1 A model with \(|S| = 3\)

The state space is \( S = \{-1, 0, 1\} \). The left-right reflection symmetry is implemented by \( R : S \rightarrow S, R\omega = -\omega \). The two conserved quantities are \( \xi(\omega) = \omega \) (the spin itself) and \( \eta(\omega) = 1 - |\omega| \) (the number of zeros). (It is easy to see that up to linear combinations these are the only two conserved quantities we can define on \( S \).) From condition (A) it follows that \( r(\omega_1, \omega_2; \omega'_1, \omega'_2) > 0 \) only if \( \omega'_1 = \omega_2 \) and \( \omega'_2 = \omega_1 \). I.e. the dynamics consists of exchanges of nearest neighbour spins. It follows that, without any restriction on the rates, condition (C) is satisfied with any probability measure \( \pi \) on \( S \). Our natural parametrization is
\[ \pi_{\rho,u}(0) = \rho, \quad \pi_{\rho,u}(\pm 1) = \frac{1 - \rho \pm u}{2}, \]
with the parameter range \( \{(\rho, u) : \rho \in [0, 1], \quad u \in [-1, 1], \quad \rho + |u| \leq 1\} \).

Condition (D) is fulfilled if and only if
\[ r(1, -1; -1, 1) - r(-1, 1; 1, -1) = r(1, 0; 0, 1) - r(0, 1; 1, 0) + r(0, -1; -1, 0) - r(-1, 0; 0, -1) \]
holds. The reflection symmetry condition (14) reads

\[ r(1, 0; 0, 1) = r(0, -1; -1, 0), \quad r(0, 1; 1, 0) = r(-1, 0; 0, -1). \]

These conditions leave us with

\[
\begin{align*}
  r(1, -1; -1, 1) &= a, & r(-1, 1; 1, -1) &= 2c + a, \\
  r(0, -1; -1, 0) &= b, & r(-1, 0; 0, -1) &= c + b, \\
  r(1, 0, 0, 1) &= b, & r(0, 1, 1, 0) &= c + b,
\end{align*}
\]

where \( a, b \geq 0 \) and \( c \geq \max\{-b, -a/2\} \) are free parameters. Without loss of generality we may choose \( c \geq 0 \) (otherwise, rename \( \tilde{\omega} := -\omega \)). It is easy to check that condition (13) is satisfied iff \((a + 2c)(b + c) > 0\). We are not interested in the \( c = 0 \) case, since that defines the reversible process which would imply diffusive rather than hyperbolic (Eulerian) scaling. By fixing an appropriate time scale we choose \( c = 1 \). It is easy to compute the microscopic fluxes \( \phi_j \) and \( \psi_j \) given by formula (5):

\[
\phi_j = \frac{1}{2} \left( \omega_j - \omega_{j+1} \right) \left( (\omega_j - 1)(1 + \omega_{j+1}) - 2a\omega_j\omega_{j+1} + 2b(1 + \omega_j\omega_{j+1}) \right),
\]

\[
\psi_j = b(\omega_{j+1}^2 - \omega_j^2) + \frac{1}{2}(1 - \omega_j)(1 + \omega_{j+1})(\omega_j + \omega_{j+1})
\]

The macroscopic fluxes are computed with formula (6). Inserted in (8) this leads to the hydrodynamic equation:

\[
\begin{align*}
  \partial_t \rho + \partial_x (\rho u) &= 0 \\
  \partial_t u + \partial_x (\rho + u^2) &= 0.
\end{align*}
\]

This system is known in the pde community as Leroux’s equation. The system has some very special features: it belongs to the so-called Temple class and it was much investigated. For details see [9]. Validity of this pde in the hydrodynamic limit up to the occurrence of shocks follows from our general Theorem.

Remark: It is an easy exercise to see that all models with \(|S| = 3\) satisfying the general conditions (A, B, C, D), without the extra assumption of left-right reflection symmetry, are essentially equivalent, in the sense that in the hydrodynamic limit they lead to pde-s which can be transformed to (15) by linear combinations of the functions involved.
4.2 A finite bricklayer model

In the following example we give a finite version of the infinite bricklayers model introduced in [11]. Let $S = \{0, 1\} \times \{-1, 1\}$. The elements of $S$ will be denoted $\omega = (n, z)$. Left-right reflection symmetry is implemented as $R: S \to S$, $R(n, z) = (n, -z)$. The conserved quantities are $\xi(\omega) = z$ and $\eta(\omega) = n$. Condition (A) leaves twenty (possibly) non-zero rates. Due to the left-right reflection symmetry conditions eight pairs of rates are equal. Using the notation $r(\omega_1, \omega_2; \omega'_1, \omega'_2) = r(n_1, n_2, n'_1, n'_2)$ in the following table we list the (possibly) non-zero rates, parametrized by twelve nonnegative parameters.

| Rate Expression | Value |
|-----------------|-------|
| $r(0, 0, 0, 0)$ | $a$ |
| $r(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \frac{1}{2})$ | $c$ |
| $r(0, 0, \frac{1}{2}, \frac{1}{2})$ | $e$ |
| $r(\frac{1}{2}, 0, \frac{1}{2}, \frac{1}{2})$ | $f$ |
| $r(0, 1, 1, 0)$ | $p$ |
| $r(1, 1, 1, 1)$ | $q$ |
| $r(0, 0, 1, 0)$ | $r$ |
| $r(1, 0, 1, 0)$ | $s$ |
| $r(0, 1, 1, 0)$ | $x$ |
| $r(1, 0, 1, 0)$ | $y$ |

All the other jump rates are zero.

It is easy to check that condition (C) imposes

$$r = s$$

and no other restriction. It also follows that the measures $\pi_{\rho, u}$ are of the product form

$$\pi_{\rho, u}(n, z) = \left(n\rho + (1 - n)(1 - \rho)\right) \frac{1 + zu}{2}, \quad n = 0, 1, \quad z = +, -,$$

with the parameters $\rho \in (0, 1), \ u \in (-1, +1)$. 
Another straightforward computation shows that condition (D) reads
\[
c + f + p + y = d + e + q + x \\
a + f + q + y = b + e + p + x
\] (18)

So, we are left with a nine-parameter family of models. Given the formulas (5) we compute the fluxes $\phi_j$ and $\psi_j$. Using the conditions (16) and (18) eventually we get

\[
2\phi_j = (b - a) + (p - q)(n_j + n_{j+1}) - (b + a)(z_{j+1} - z_j) \\
+ (a + b - e - f - x - y)(n_j + n_{j+1})(z_{j+1} - z_j) + (a - b)z_{j+1}z_j \\
- (a + b + c + d - 2e - 2f - 2x - 2y)n_jn_{j+1}(z_{j+1} - z_j) \\
- (p - q)(n_j + n_{j+1})z_{j+1}z_j
\]

\[
4\psi_j = -(p + q + r + s + x + y)(n_{j+1} - n_j) \\
+ (p - q)(n_j + n_{j+1})(z_j + z_{j+1}) + (y - x)(n_{j+1} - n_j)(z_{j+1} - z_j) \\
- 2(p - q)n_jn_{j+1}(z_j + z_{j+1}) \\
- (p + q - r - s - x - y)(n_{j+1} - n_j)z_{j+1}z_j
\]

The macroscopic fluxes are again explicitly computable. From (6) and (17) we get

\[
\Phi(\rho, u) = (\rho - (a - b)/2)(1 - u^2), \\
\Psi(\rho, u) = (p - q)\rho(1 - \rho)u.
\]

Without loss of generality we may assume $p - q \geq 0$ (otherwise rename the microscopic variables $\tilde{n}_j := n_j$, $\tilde{z}_j := -z_j$). Further on, $p = q$ leads to diffusive rather than hyperbolic (Eulerian) scaling of the particle density, so we are interested in the $p > q$ cases only. By setting the appropriate time scale we can choose $p - q = 1$ and denote $\gamma := \frac{a - b}{2(p - q)}$. So, eventually we get the system of pdes

\[
\begin{align*}
\partial_t \rho + \partial_x (\rho(1 - \rho)u) &= 0 \\
\partial_t u + \partial_x ((\rho - \gamma)(1 - u^2)) &= 0
\end{align*}
\] (19)

In [16] another family of four-state models with two conserved quantities, the so-called two channel traffic models are analyzed. These models also satisfy conditions (A), (B), (C) and (D). As a consequence our general Theorem is applicable to the two channel traffic models, too.
About the relation of our four state deposition models (treated in this subsection) and the two channel traffic models treated in [6]: Due to the different symmetry conditions imposed — we impose the left-right reflection symmetry described in the first paragraph of this section, while in [6] symmetry between the two traffic channels is imposed — the two families of models do not intersect. The one parameter family of partial differential equations derived in [6] essentially differs from our partial differential equations (19). (Actually there is no parameter value for which the two pde-s are equivalent.) However, the two families of models show many similarities and do have common generalizations.

5 Sketch of proof

The present section is divided into four subsections. In subsection 5.1 we present the first steps of the ‘relative entropy method’ applied. As there is no real novelty in this part, we only list the main steps without the computational details which are essentially the same as in the original work [13] of Yau or in Chapter 6. of [1] or in [3].

It turns out that for a general two (or more) component system some identity relating the macroscopic fluxes $\Phi$ and $\Psi$ is essentially needed for completing the proof. These relations are reminiscent of Onsager’s reciprocity relations of nonequilibrium thermodynamics, see e.g. Chapter 10.D of [7]. However an essential difference is worth noting: while the traditional Onsager relations are derived under the condition of reversibility of the microscopic dynamics, in our case conditions (A), (C) and (D) are involved which do not imply reversibility by any means. Seemingly, these relations were not explicitly noted so far in the context of mathematically rigorous hydrodynamic limits. This omission is probably explained by the fact that in the concrete models investigated so far these identities just dropped out without any computations.

In subsection 5.2 we prove that under the conditions (A), (C) and (D) these identities hold in general. We shall refer to these identities as Onsager relations. It also follows from these identities that the systems of partial differential equations arising as hydrodynamic limits under Eulerian scaling are indeed of hyperbolic type and the thermodynamic equilibrium entropy $S(u, v)$ is globally convex Lax entropy of the hydrodynamic equations, as it
is commonly assumed. In subsection 5.3 we formulate the consequences of
the Onsager relations which are crucial for the further steps of the proof of
the hydrodynamic limit.

Finally, in subsection 5.4 we sketch the last steps of the proof. Here
again we follow the standard steps of the relative entropy method, so we
omit all computational details, referring only to the main stations of the
proof. For the computational details of subsections 5.1 and 5.4 we refer
the reader to Chapter 6. of [4] or to [3]. However, we warn the reader
that the omitted details (in particular the last two steps: the control of the
block replacement and the one-block estimate) are rather sophisticated and
mathematically deep.

5.1 First transformations

In order to obtain the main estimate (12) our aim is to get a Grönwall type
inequality: we will prove that for every $t \in [0, T]$

$$H^N(t) - H^N(0) \leq C \int_0^t H^N(s) ds + o(N),$$

(20)

where the error term is uniform in $t \in [0, T]$. Because it is assumed that
$H^N(0) = o(N)$, the Theorem follows.

For proving (20) we try to bound (from above) $\partial_t H^N(s)$ by $\text{const} \cdot
H^N(s) + o(N)$, uniformly for $s \in [0, T]$. We start form the inequality (21)
which is derived in [4] under very general conditions, valid in our case.

$$\partial_t H^N(t) \leq N \int_{\Omega^N} \frac{L^N f^N_{t}}{f^N_{t}} d\mu^N_t - \int_{\Omega^N} \frac{\partial \phi}{f^N_{t}} d\mu^N_t.$$  

(21)

Next we transform the two terms appearing on the right hand side of (21).
Equation (22) follows form the smoothness of the functions $\theta(t, x)$ and $\tau(t, x)$
and from the entropy inequality applied to the measures $\mu^N_t$ compared with
the absolute reference measure $\pi^N$.

$$N \int_{\Omega^N} \frac{L^N f^N_{t}}{f^N_{t}} d\mu^N_t = - \sum_{j \in \mathbb{T}^N} \partial_x \theta(t, j/N) \int_{\Omega^N} \phi_j d\mu^N_t$$

$$- \sum_{j \in \mathbb{T}^N} \partial_x \tau(t, j/N) \int_{\Omega^N} \psi_j d\mu^N_t$$

$$+ O(1)$$

(22)
Equation (23) follows from direct computation of the time derivative of the function $f^N_t$.

$$
\int_{\Omega^N} \frac{\partial f^N_t}{f^N_t} d\mu^N_t = \sum_{j \in T^N} \partial_t \theta(t, j/N) \int_{\Omega^N} (\xi_j - u(t, j/N)) d\mu^N_t + \sum_{j \in T^N} \partial_t \tau(t, j/N) \int_{\Omega^N} (\eta_j - v(t, j/N)) d\mu^N_t
$$

Next we replace the local variables $\phi_j$ and $\psi_j$ in (22), respectively, $\xi_j$ and $\eta_j$ in (23) by their block averages defined as follows: if $\delta_j$ is a local microscopic variable its block average is defined as

$$
\delta^*_l := \frac{\delta_j + \cdots + \delta_{j+l-1}}{l}.
$$

In the following two block-replacements we use again the smoothness of the functions $\theta(t, x)$ and $\tau(t, x)$ and the entropy inequality applied to the measures $\mu^N_t$ compared with the absolute reference measure $\pi^N$.

$$
N \int_{\Omega^N} \frac{L^N f^N_t}{f^N_t} d\mu^N_t = - \sum_{j \in T^N} \partial_x \theta(t, j/n) \int_{\Omega^N} \phi^l_j d\mu^N_t - \sum_{j \in T^N} \partial_x \tau(t, j/n) \int_{\Omega^N} \psi^l_j d\mu^N_t + O(l)
$$

$$
\int_{\Omega^N} \frac{\partial f^N_t}{f^N_t} d\mu^N_t = \sum_{j \in T^N} \partial_t \theta(t, j/N) \int_{\Omega^N} (\xi^l_j - u(t, j/N)) d\mu^N_t + \sum_{j \in T^N} \partial_t \tau(t, j/N) \int_{\Omega^N} (\eta^l_j - v(t, j/N)) d\mu^N_t + O(l)
$$

The last transformation of this first, preparatory part is replacing in (24) the block averages $\phi^l_j$, respectively, $\psi^l_j$ by their equilibrium averages computed at the empirical densities, $\Phi(\xi^l_j, \eta^l_j)$, respectively, $\Psi(\xi^l_j, \eta^l_j)$. The error terms appearing in the third and fourth lines of the right hand side of (25) are the most important error terms to be controlled by the so called one block
estimate towards the end of the proof.

\[
N \int_{\Omega^N} \frac{L}{f_i^N} \int_{f_i^N} \Lambda \mu_i^N = - \sum_{j \in T^N} \partial x(t, j/n) \int_{\Omega^N} \Phi(\xi_j^t, \eta_j^t) d\mu_i^N \\
- \sum_{j \in T^N} \partial x(t, j/n) \int_{\Omega^N} \Psi(\xi_j^t, \eta_j^t) d\mu_i^N \\
- \sum_{j \in T^N} \partial x(t, j/n) \int_{\Omega^N} \left( \phi_j^t - \Phi(\xi_j^t, \eta_j^t) \right) d\mu_i^N \\
- \sum_{j \in T^N} \partial x(t, j/n) \int_{\Omega^N} \left( \psi_j^t - \Psi(\xi_j^t, \eta_j^t) \right) d\mu_i^N \\
+ O(l)
\]  

(26)

Before going on with the standard steps of the relative entropy proof we need to make a detour.

5.2 An Onsager type identity

**Lemma 1.** Suppose we have a particle system with two conserved quantities and rates satisfying conditions \([A], [C]\) and \([D]\). Then there exists a potential function \((\theta, \tau) \mapsto U(\theta, \tau)\) such that

\[
\Phi(\theta, \tau) := \Phi(u(\theta, \tau), v(\theta, \tau)) = U'_\theta, \\
\Psi(\theta, \tau) := \Psi(u(\theta, \tau), v(\theta, \tau)) = U'_\tau,
\]

or, equivalently

\[
\Phi'_\tau = \Psi'_\theta.
\]

(27)

**Proof.** We prove (28). Throughout the forthcoming proof we adopt the notation \(\xi_j := \xi(\omega_j), \xi_j' := \xi(\omega_j')\), etc.

From the definitions

\[
\pi_{\theta, \tau}(\omega_1)\pi_{\theta, \tau}(\omega_2) = \exp\{\theta(\xi_1 + \xi_2) + \tau(\eta_1 + \eta_2) - 2G(\theta, \tau)\}\pi(\omega_1)\pi(\omega_2),
\]

and

\[
\left(\pi_{\theta, \tau}(\omega_1)\pi_{\theta, \tau}(\omega_2)\right)'_\theta = \\
\pi(\omega_1)\pi(\omega_2)e^{\theta(\xi_1 + \xi_2) + \tau(\eta_1 + \eta_2) - 2G(\theta, \tau)}\{\xi_1 + \xi_2\} = \\
\frac{\pi(\omega_1)\pi(\omega_2)}{Z(\theta, \tau)^3} \sum_{\omega_3 \in S} \pi(\omega_3)(\xi_1 + \xi_2 - 2\xi_3)e^{\theta(\xi_1 + \xi_2 + \xi_3) + \tau(\eta_1 + \eta_2 + \eta_3)},
\]

(28)
where \( Z(\theta, \tau) = \exp\{G(\theta, \tau)\} \). Similarly,

\[
(\pi_{\theta, \tau}(\omega_1) \pi_{\theta, \tau}(\omega_2))'_{\tau} = \frac{\pi(\omega_1)\pi(\omega_2)}{Z(\theta, \tau)^3} \sum_{\omega_3 \in S} \pi(\omega_3)(\eta_1 + \eta_2 - 2\eta_3)e^{\theta(\xi_1 + \xi_2 + \xi_3 + \tau(\eta_1 + \eta_2 + \eta_3))}.
\]

Hence

\[
\Phi'(\theta, \tau) = \frac{1}{Z(\theta, \tau)^3} \sum_{\omega_1, \omega_2, \omega_3 \in S} \pi(\omega_1)\pi(\omega_2)\pi(\omega_3)e^{\theta(\xi_1 + \xi_2 + \xi_3 + \tau(\eta_1 + \eta_2 + \eta_3))} \times (\eta_1 + \eta_2 - 2\eta_3) \sum_{\omega_1', \omega_2' \in S} r(\omega_1, \omega_2, \omega_1', \omega_2')(\xi_2' - \xi_2),
\]

\[
\Psi'(\theta, \tau) = \frac{1}{Z(\theta, \tau)^3} \sum_{\omega_1, \omega_2, \omega_3 \in S} \pi(\omega_1)\pi(\omega_2)\pi(\omega_3)e^{\theta(\xi_1 + \xi_2 + \xi_3 + \tau(\eta_1 + \eta_2 + \eta_3))} \times (\xi_1 + \xi_2 - 2\xi_3) \sum_{\omega_1', \omega_2' \in S} r(\omega_1, \omega_2, \omega_1', \omega_2')(\eta_2' - \eta_2),
\]

For the proof of the lemma it is enough to prove for any \( K \in \lbrack 3 \min \xi, 3 \max \eta \rbrack \) and \( L \in \lbrack 3 \min \eta, 3 \max \eta \)

\[
\sum_{\omega_1, \omega_2, \omega_3, \omega_1', \omega_2' \in S; \xi_1 + \xi_2 + \xi_3 = K \atop \eta_1 + \eta_2 + \eta' = L} \pi(\omega_1)\pi(\omega_2)\pi(\omega_3)r(\omega_1, \omega_2; \omega_1', \omega_2') \times ((\eta_1 + \eta_2 - 2\eta_3)(\xi_2' - \xi_2) - (\xi_1 + \xi_2 - 2\xi_3)(\eta_2' - \eta_2)) = 0
\]

From condition \([A]\) imposed on the rate functions it follows that in all nonzero terms of the above sum one can replace \( \eta_1 + \eta_2 \) by \( \eta'_1 + \eta'_2 \) and \( \eta'_2 - \eta_2 \) by \( \eta_1 - \eta'_1 \), and similarly for the \( \xi \)-s. After straightforward computations this equation (still to be proved) becomes

\[
\sum_{\omega_1, \omega_2, \omega_3, \omega_1', \omega_2' \in S; \xi_1 + \xi_2 + \xi_3 = K \atop \eta_1 + \eta_2 + \eta' = L} \pi(\omega_1)\pi(\omega_2)\pi(\omega_3)r(\omega_1, \omega_2; \omega_1', \omega_2') \times (\Delta(\omega_1, \omega_2, \omega_3) + \Delta(\omega_2', \omega_1', \omega_3)) = 0
\]

where \( \Delta : S \times S \times S \rightarrow Z \) is defined as follows

\[
\Delta(\omega_1, \omega_2, \omega_3) := \xi_1(\eta_2 - \eta_3) + \xi_2(\eta_3 - \eta_1) + \xi_3(\eta_1 - \eta_2).
\]

Note that \( \Delta \) is antissymetric regarding permutation of its variables.

Next, from condition \([C]\) it follows that the contribution of the two terms on the left hand side of the previous equation is the same. Thus, it is to be
proved that
\[
\sum_{\omega_1, \omega_2, \omega_3, \omega'_1, \omega'_2 \in S: \xi_1 + \xi_2 + \xi' = K} \pi(\omega_1) \pi(\omega_2) r(\omega_1, \omega_2; \omega'_1, \omega'_2) \Delta(\omega_1, \omega_2, \omega_3) = \\
\sum_{\omega_1, \omega_2, \omega_3 \in S: \xi_1 + \xi_2 + \xi' = K} \pi(\omega_1) \pi(\omega_2) R(\omega_1, \omega_2) \Delta(\omega_1, \omega_2, \omega_3) = 0
\]

Finally, from the antisymmetry of the function \(\Delta\) and condition (3) imposed on the function \(R\) it follows indeed that this last sum equals zero.

\[\square\]

5.3 Consequences of the Onsager relations

Relation (28) is the same as saying that the matrix \(D(u(\theta, \tau), v(\theta, \tau)) \cdot G''(\theta, \tau)\) is symmetric. Using (4) this also reads as
\[
S''(u, v) \cdot D(u, v) = (S''(u, v) \cdot D(u, v))^\dagger.
\]

This relation implies that only hyperbolic two-by-two systems of conservation laws (8) can arise as hydrodynamic limits. Indeed, as the following elementary argument shows relation (29) can hold with a positive definite matrix \(S''\) only if \(D(u, v)\) can be diagonalized (in the real sense), which is exactly the condition of hyperbolicity of the system (8). Indeed, since \(S''\) is positive definite, we can write
\[
D = (S'')^{-1/2} \left( (S'')^{-1/2} (S'' D) (S'')^{-1/2} \right) (S'')^{1/2},
\]
which means that \(D\) is similar to the real symmetric matrix \((S'')^{-1/2} (S'' D) (S'')^{-1/2}\), and from this the (real) diagonalizability of \(D\) follows. Furthermore, (29) is spelled out as
\[
S''_{uv} \Phi'_v + S''_{vu} \Psi'_u = S''_{vu} \Phi'_u + S''_{uv} \Psi'_v,
\]
which is readily recognized as the partial differential equation defining the Lax entropies of the system (8). The function \(F(u, v) := U(\theta(u, v), \tau(u, v))\) is the corresponding (macroscopic) entropy-flux. See (3) or (4) for the pde notions involved. Thus, part (i) of the Theorem is proved.

Now we turn to two further consequences of Lemma 1 which turn out to be of crucial importance in the hydrodynamic behavior.
First, the time derivatives of \( \theta \) and \( \tau \) are expressed. From the pde (8) it follows that
\[
\partial_t \theta = -\theta' u \Phi' u - \theta' v \Phi' v - \theta' u \Psi' u - \theta' v \Psi' v.
\]
Using the identity (31) we replace \( \theta' u \Phi' v = \theta v \Phi' u + \tau' v \Psi' u - \tau' u \Psi' v \) in the second term of the right hand side. Using also the straightforward identities \( u' \tau = v' \theta \) and \( \theta' v = \tau' u \) (see subsection 2.4) we finally get
\[
\partial_t \theta = \Phi' u \partial_x \theta + \Psi' u \partial_x \tau, \tag{32}
\]
and by identical considerations
\[
\partial_t \tau = \Phi' v \partial_x \theta + \Psi' v \partial_x \tau. \tag{33}
\]

Second, due to identity (27),
\[
\sum_{j \in T_N} \left( \partial_x \theta(j/N) \Phi(\xi_{j,j}, \eta_{j,j}) + \partial_x \tau(j/N) \Psi(\xi_{j,j}, \eta_{j,j}) \right)
= \sum_{j \in T_N} \partial_x U(\xi_{j,j}, \eta_{j,j}) = O(1). \tag{34}
\]

5.4 End of proof

Now we return to proving (20). Denote
\[
\mathcal{D}(u, v; \tilde{u}, \tilde{v}) := \Phi(\tilde{u}, \tilde{v}) - \Phi(u, v) - \Phi'_u(u, v)(\tilde{u} - u) - \Phi'_v(u, v)(\tilde{v} - v)
\]
and similarly for \( \mathcal{D}(u; v; \tilde{u}, \tilde{v}) \). Applying (32), (33) and (34), from (24) and (26) we obtain
\[
\int_{\Omega_N} \frac{\partial_t f^N_i - NL v^N f^N_i}{f^N_i} d\mu^N_i = \tag{35}
\]
\[
\sum_{j \in T_N} \partial_x \theta(t, j/n) \int_{\Omega_N} \mathcal{D}(u(t, j/N), v(t, j/N); \xi_{j,j}^l, \eta_{j,j}^l) d\mu^N_i
+ \sum_{j \in T_N} \partial_x \tau(t, j/n) \int_{\Omega_N} \mathcal{D}(u(t, j/N), v(t, j/N); \xi_{j,j}^l, \eta_{j,j}^l) d\mu^N_i
+ \sum_{j \in T_N} \left( \phi_{j,j}^l - \Phi(\xi_{j,j}, \eta_{j,j}) \right) d\mu^N_i
+ \sum_{j \in T_N} \left( \psi_{j,j}^l - \Psi(\xi_{j,j}, \eta_{j,j}) \right) d\mu^N_i
+ O(l)
\]
The first two terms on the right hand side of \((35)\) are estimated by the entropy inequality, comparing the measure \(\mu_t^N\) with the local equilibrium measure \(\nu_t^N\):

\[
\sum_{j \in T^N} \int_{\Omega^N} \left( |D\Phi(u(t,j/N), v(t,j/N); \xi_j^l, \eta_j^l)| + |D\Psi(u(t,j/N), v(t,j/N); \xi_j^l, \eta_j^l)| \right) d\mu_t^N
\leq CH^N(t) + O(N^{-1}).
\]

The last two terms in \((35)\) are estimated only integrated against time. Applying the so-called one block estimate (see e.g. Chapter 5 of [4]) one gets

\[
\lim_{l \to \infty} \lim_{N \to \infty} N^{-1} \sum_{j \in T^N} \int_0^t ds \int_{\Omega^N} \left| \phi_j^l - \Phi(\xi_j^l, \eta_j^l) \right| d\mu_t^N = 0,
\]

\[
\lim_{l \to \infty} \lim_{N \to \infty} N^{-1} \sum_{j \in T^N} \int_0^t ds \int_{\Omega^N} \left| \psi_j^l - \Psi(\xi_j^l, \eta_j^l) \right| d\mu_t^N = 0.
\]

This is the only part of the proof where condition \((3)\) is used, which ensures ergodicity of the Markov process \(X_t^N\) on the ‘hyperplanes’ \(\Omega_{KL}^N\).

Finally, inserting \((36)\) and \((37)\) in \((35)\), via \((21)\) we obtain \((20)\) and thus the part (ii) of the Theorem is also proved.

6 Particle systems with several conserved variables

As noted in the introduction, the results described in the previous sections are also valid for particle systems with more than 2 conserved quantities.

Before we formulate the general results we have to summarize some notations. Let \(n \geq 2\) be fixed integer, and \(\xi = (\xi^1, \xi^2, \ldots, \xi^n) : S \to \mathbb{R}^n\) the vector of conserved quantities. Throughout the present section bold face symbols will denote \(n\)-vectors.

We require the rate function to satisfy similar conditions as listed in subsection 2.2 (in place of conditions \((3)\) and \((4)\) we need the suitable generalizations). For every \(\theta \in \mathbb{R}^n\) we can define momentum generating function \(G(\theta)\) as

\[
G(\theta) := \log \sum_{\omega \in S} e^{\theta \xi(\omega)} \pi(\omega),
\]
and the probability measures

\[ \pi_\theta(\omega) := \pi(\omega) \exp(\theta \cdot \xi(\omega) - G(\theta)) \]

\[ \pi^N_\theta := \prod_{j \in T^N} \pi_\theta \]

on \( S \), respectively, on \( \Omega^N \). We define the expectation of the conserved quantities with respect to the measure \( \pi^N_\theta \):

\[ u(\theta) := E_\theta(\xi) = \nabla_\theta G(\theta). \]

One can easily show, that \( \nabla_\theta^2 G(\theta) = \text{Cov}_\theta(u, u) \) is positive definite. As a consequence, the function \( \theta \mapsto u \) is invertible, and

\[ \theta(u) = \nabla u S(u), \]

where \( S(u) \) is the convex conjugate of \( G(\theta) \):

\[ S(u) := \text{sup}_{u \in \mathbb{R}^n} (u \cdot \theta - G(\theta)). \]

We introduce the flux of the vector of the conserved quantities and its expectation:

\[ \phi(\omega_1, \omega_2) := \sum_{\omega_1', \omega_2' \in S} r(\omega_1, \omega_2; \omega_1', \omega_2')(\xi(\omega_2') - \xi(\omega_2)) \]

\[ \Phi(u) := E_{\theta(u)} \phi \]

\[ = \sum_{\omega_1, \omega_2 \in \omega_1', \omega_2' \in S} r(\omega_1, \omega_2; \omega_1', \omega_2')(\xi(\omega_2') - \xi(\omega_2)) \pi_u(\omega_1) \pi_u(\omega_2). \]

Now we are able to formulate results of the previous sections in the more general setting.

Using the arguments presented in section \( \mathbb{I} \) one can show that under Eulerian scaling the vector of the local densities of the conserved quantities \( u(t, x) \) evolve according to the following \( n \)-component partial differential equation:

\[ \partial_t u + \partial_x \Phi(u) = 0. \] (38)

Lemma \( \mathbb{I} \) applies for any two conserved quantities \( \xi^i, \xi^j \) (\( i \neq j \)), thus if we denote the derivative matrix of the flux vector \( \Phi(u) \) by \( D(u) := \nabla u \Phi(u) \)
and the second derivative matrix of the thermodynamic entropy \( S''(u) := \nabla_u^2 S(u) \), we get
\[
S''(u) \cdot D(u) = (S''(u) \cdot D(u))^\dagger
\] (39)
