Abstract: Optical complexity and various properties of Case 2 waters make it essential to derive inherent optical properties (IOPs) through an appropriate method. Based on field measured data of Lake Chaohu between 2009 and 2018, the quasi-analytical algorithm (QAA) was modified for the particular scenario of that lake to derive absorption coefficients based on the moderate-resolution imaging spectroradiometer (MODIS) bands. By changing the reference wavelength to longer ones and building a relationship between the value of spectral power for particle backscattering coefficient (Y), suspended particulate matter (SPM), and above-surface remote-sensing reflectance (Rrs), we improved the accuracy of the retrieval of total absorption coefficients. The absorption coefficients of gelbstoff and non-algal particulates (adg) and absorption coefficients of phytoplankton (aph) in Lake Chaohu were also derived by changing important parameters according to Lake Chaohu. The derived aph tend to be bigger than measured aph in this study, while derived adg tend to be smaller than measured data. We also used the corrected MODIS surface reflectance product (MOD09/MYD09) to calculate the aph(443), aph(645), and aph(678) by the model proposed in this study. It shows that in summer and autumn, aph tended to be higher in the northwestern part of Lake Chaohu, and were relatively lower in the spring and winter, which is similar to previous studies. Overall, our study provides an algorithm that is effectively used in the case of Lake Chaohu and applicable to the data obtained by MODIS, which can be used for further study to investigate the change law of absorption coefficients in long time series by applying MODIS data.

Keywords: inherent optical properties (IOPs); absorption coefficients; quasi-analytical algorithm (QAA); MODIS; Lake Chaohu

1. Introduction

The inversion of water color involves the derivation of inherent optical properties (IOPs) from apparent optical properties (AOPs). As a result, information about water constituents is retrieved from derived IOPs, such as concentrations of chlorophyll-a (Chl a), suspended sediments, and colored, dissolved organic matter (CDOM).

Recent studies have emphasized the importance of retrieving IOPs through remote sensing. Variations in IOPs can precisely indicate changes in water constituents and mass. AOPs refer to the parameters that vary with the change of illumination conditions, including water-leaving radiance (Lw), above-surface remote-sensing reflectance (Rrs), and so on [1]. The IOPs and light field together determine the AOPs. The inversion of the IOPs can be achieved by using the related algorithms from
the AOPs. Rs is one of the most important AOPs, which is determined by the IOPs of the water body and the geometric structure of the underwater light field. Through the IOPs (absorption and scattering), inherent nonlinear intrinsic correlations exist between the concentration of each component and the remote-sensing reflectance.

Solutions to accurately derive the optical properties remotely have been studied for many years, and scientists have proposed algorithms related to this subject. Empirical algorithms use certain regressions between the IOPs and the ratios of below-surface remote sensing reflectance ($r_{rs}$) or $R_{rs}$. The main advantage of such an algorithm is that data processing is simple and rapid, which is essential in retrieving information from satellite sensors. However, due to the lack of a certain physical foundation, empirical models often rely too much on field-measured data, which are limited by time and region. Therefore, the applicability of those algorithms may be limited and may result in errors in different areas [2]. A semi-analytical model is based on the radiative transfer equation between the water composition, IOPs, and AOPs. These algorithms are suitable for various water types and are much more accurate than empirical algorithms [3,4]. Based on the basic theory of optical properties and the spectral model of water bodies, the quantitative relationship between the substance concentration in water and the optical properties of the water body can be established, which is called an analytical model. This model can be used for the large-scale and long-term monitoring of water color and quality. However the theoretical research and data measurement in different waters have not reached a perfect, applicable level.

Extensive work has been conducted on the inversion of IOPs in China and abroad, and the inversion model has gradually progressed from the traditional empirical model to the semi-analytical model. Carder et al. [3,5] presented a moderate-resolution imaging spectroradiometer (MODIS) semi-analytical algorithm, which can use $R_{rs}$ to retrieve IOPs including absorption and backscattering coefficients. Hoge and Lyon [6,7] created a linear matrix inversion model by using $R_{rs}$ at 412, 490, and 555 nm and retrieved the IOPs of the water body. Doerffer built a retrieval procedure of suspended particulate matter (SPM), chlorophyll, and gelbstoff concentration based on neutral network [8]. Lee et al. [9] investigated a quasi-analytical algorithm (QAA) that can retrieve IOPs by using multi-band $R_{rs}$ data. This algorithm is applicable to hyperspectral data and multi-band satellite sensor data that have been or will be launched, such as the coastal zone color scanner (CZCS), the sea-viewing, wide field-of-view sensor (SeaWiFS), and MODIS [9]. It is derived from the analytical, semi-analytical, and empirical formulas for oceanic and coastal waters. It was updated to QAA_v6 in the following years [10].

QAA is one of the mainstream models at present. It has the characteristics of high precision and fast operation speed and can be used to process large quantities of data. In recent years, many scholars in China have conducted research on the application of QAA in coastal waters in the country [11–13]. For inland Case 2 waters, whose optical properties are significantly influenced by mineral particles, CDOM, or microbubbles [14], Le et al. [15,16] validated and improved the QAA algorithm in Lake Taihu; the results showed that the reference wavelength has to be longer in turbid waters. Xie et al. [17] applied the QAA to the inversion of the IOPs of Lake Kuncheng. Domestic research on IOPs mainly focuses on the inversion of ocean IOPs and the backscattering coefficient of inland water, but the inversion of the absorption coefficient of inland water is less studied [18]. Although QAA is widely used, there are still many uncertainties in deriving optical properties for optically complex Case 2 waters [16,19,20]. Specifically, the reference wavelength and the empirical formulas do not work for inland Case 2 waters, especially for the case of Lake Chaohu, which is a lake of high turbidity, Chl a concentrations, and complicated optical properties.

This study aimed to provide a solution to derive IOPs of Lake Chaohu by applying MODIS data. The time resolution of MODIS is effective for further study to investigate the change law of IOPs of Lake Chaohu in the long time series. In this paper, the derived absorption coefficients and measured absorption coefficients were compared and analyzed. Thereafter, some test data were used to measure
2.1. Study Area

Lake Chaohu (31°25′–31°43′N, 117°17′–117°51′E, Figure 1) is an eutrophic and turbid shallow lake in Anhui Province, in the east of China, with an acreage of 770 km² and an average depth of 3.0 m [21]. This lake is an important source of fish and drinking water for Hefei, a city under a subtropical monsoon climate (Figure 1). Lake Chaohu has a volume of $32.3 \times 10^8$ m³ during the rainy season for approximately five months and only $17.2 \times 10^8$ m³ during the dry season for approximately seven months [22]. Around 9 million people live around the lake, in which the main contamination sources are agricultural, industrial, and municipal pollution [23,24]. Lake Chaohu has had poor water quality and frequent algal blooms, particularly cyanobacteria blooms, over the past few decades [25].

![Figure 1. The study area and samples in Lake Chaohu, China, during 11 cruise surveys from October 2009 to July 2018.](image)

2.2. Sampling and Data Collection

We conducted 11 cruise surveys, with 119 surface samples from October 2009 to July 2018 to measure optical properties in Lake Chaohu in this study (Figure 1). From this, 94 samples were used to build models and 25 samples were used as test data. We measured $R_{rs}$ data at the sites. The water samples were kept at 4 °C in the dark before experiments of SPM, Chl $a$, dissolved organic carbon concentration (DOC), and absorption coefficients.

Measurements of Relevant Parameters

A handheld ASD (analytical spectral device) under the NASA Ocean Optics protocols was used to obtain $R_{rs}$ [26]. Applying the method described by Mobley et al. [27], the viewing direction was 40 degree from the nadir and 135 degree from the Sun.

We filtered the water samples by Whatman GF/C glass-fiber filters with a pore size of approximately 1.2 µm and extracted pigments with a reference of 90% acetone. We used a Shimadzu UV-2600 (Kyoto, Japan) to measure the absorbance then achieved Chl $a$ data [28]. We pre-combusted Whatman GF/F glass-fiber filters with a pore size of 0.7 µm at 450 °C for 6 h and pre-weighed them. We then filtered the water samples and dried them at high temperature (105 °C) for approximately 4–6 h for the measurement of SPM concentrations. Suspended particulate inorganic matter (SPIM) was similarly measured through weighing the filters before and after burning organic matter for 6 h [29].
The absorption coefficients of total particulate matter, absorption coefficients of non-algal particulate \((a_d)\), and absorption coefficients of phytoplankton \((a_{ph})\) at 350–800 nm were obtained by using the same machine with GF/F filters [26]. The baseline was obtained by a blank filter with distilled water [2]. The \(a_d\) was measured after the pigments were bleached with sodium hypochlorite, and then \(a_{ph}\) were derived. The absorption coefficient of CDOM \((a_g)\) was measured using the same machine with Milli-Q water as the reference from water filtered by filters with a 0.22-µm pore size from 280 to 700 nm (1-nm interval) [2,30,31].

2.3. Satellite Image Data Preprocessing

In this study, MODIS data were selected as input data. MODIS has high spectral and time resolutions. It is set on Terra and Aqua and has five levels of data products. MODIS provides continuous global remote sensing data that have a wide range of applications in ecology and geography research. The MODIS data preprocessing in this study mainly refer to the geometric correction and atmospheric correction of the MODIS surface reflectance product (MOD09/MYD09) in Lake Chaohu.

2.3.1. The MOD09/MYD09 Product

The MOD09/MYD09 surface reflectance product can be used in the calculation of the Earth’s surface albedo [32,33]. It belongs to the terrestrial product and corresponds to the Terra and Aqua satellites, respectively. MOD09/MYD09 has reflectance data with 250-m resolution of Bands 1 and 2 (620–670 nm and 841–876 nm), 500-m resolution of Bands 1–7 (620–670 nm, 841–876 nm, 459–479 nm, 545–565 nm, 1230–1250 nm, 1628–1652 nm, and 2105–2155 nm), 1-km resolution of Bands 1–16 (620–670 nm, 841–876 nm, 459–479 nm, 545–565 nm, 1230–1250 nm, 1628–1652 nm, 2105–2155 nm, 405–420 nm, 438–448 nm, 483–493 nm, 526–536 nm, 546–556 nm, 662–672 nm, 673–683 nm, 743–753 nm, and 862–877 nm), multi-resolution pixel state QA (quality assessment) data, and 1-km observation statistics. In the QA data, the type of ground cover is indicated. MOD09/MYD09 data (hereinafter referred to as MOD09) are based on Level1B data, which are corrected for the effects of low atmospheric gases and aerosols. Atmospheric correction aims to remove the impact of Sun glint, residual aerosol scattering, and so on. Given the requirements of lake water bodies for reflectance data, MOD09 data are still insufficient for Case 2 water body monitoring. In order to eliminate residual effects, further correction is needed.

2.3.2. The MOD09 Correction Method

The atmosphere is an important factor affecting the quantitative analysis and application of remote sensing. Therefore, removing the effects of atmospheric scattering and absorption from the radiance value received by the sensor has become the premise of remote sensing quantitative analysis. In some studies, MOD09 reflectance data are used directly [34–36]. Nevertheless, by comparing MOD09 data and measured data, it has been found that the MOD09 data generally show higher phenomena in some bands compared with the measured data [37].

In this study, we used a simple correction method based on near-infrared (NIR) and short-wave infrared (SWIR) bands [37]. The advantage of using this correction method is that it can eliminate the noise in MOD09 data by simple correction and then convert the surface reflectance to the scale of remote-sensing reflectance, so that a more accurate \(R_{rs}\) is obtained and can be more easily applied to processing. The specific correction method is as follows:

\[
R_{rs}(λ) = \frac{R(λ) - \min(R_{NIR} : R_{SWIR})}{π}
\]

where \(\min(R_{NIR} : R_{SWIR})\) refers to the minimum reflectance value of NIR and SWIR bands. Due to the strong absorption of water in the NIR and SWIR bands, reflectance will generally drop to 0 in the NIR band in the case of general water, while reflectance will generally decrease to 0 in the SWIR band in the
case of turbid water [38]. Therefore, the reflectance value of the NIR and SWIR bands is considered as additive noise. The additive noise can be eliminated by subtracting the value from each band value.

After the correction by this method, there are still some gaps between the corrected $R_{rs}$ and the measured values at 748 nm (Figure 2a). Therefore, this study used the least-square method to calibrate the values at 748 nm, again based on the measured data. The equation between the measured $R_{rs}$ and the values derived from MOD09 is constructed to make the values closer to the measured data. The $R_{rs}$ after recalibration is shown in Figure 2b (N = 79). Similarly, the $R_{rs}$ values at 413 and 443 nm were also corrected again using this method.

![Figure 2](image-url)

**Figure 2.** Measured above-surface remote-sensing reflectance ($R_{rs}$) and $R_{rs}$ derived from MODIS surface reflectance product (MOD09) at 748 nm (a) before recalibration and (b) after recalibration.

### 3. Improving QAA

QAA is a semi-analytical method for calculating the absorption coefficient and backscattering coefficient of water proposed by Lee et al. [9]. The inversion process of QAA has two parts. The first one is deriving the total absorption coefficient and backscattering coefficient. The second, utilizing the coefficient of the total absorption obtained from the first part, is decomposing the total absorption coefficient into different elements. The QAA algorithm is proposed for open ocean and coastal waters; accordingly, some empirical formulas are used for specific research areas, which cannot be directly applied to the inversion of the absorption coefficients for inland Case 2 waters.

#### 3.1. Inversion of Total Absorption Coefficients

In the first part of QAA, a relationship between $R_{rs}$ and total absorption coefficients was established. Similarly in this study, a new relationship needs to be established according to Lake Chaohu by changing some parameters and formulas as follows.

##### 3.1.1. Values of $g_0$ and $g_1$

$$u(\lambda) = -g_0 + [(g_0)^2 + 4g_1r_{rs}(\lambda)]^{1/2}/2g_1$$

(2)

The ratio of backscattering coefficient to the sum of absorption and backscattering coefficients ($u(\lambda)$) is calculated by $r_{rs}$ and $g_0$, $g_1$. Gordon et al. [39] found the values of $g_0 = 0.0949$ and $g_1 = 0.0794$ for oceanic Case 1 waters, whose optical properties are determined primarily by phytoplankton, CDOM, and detritus degradation products [40]. Lee et al. [9,41] advised that $g_0 = 0.084$ and $g_1 = 0.17$ is more accurate for higher-scattering coastal waters. In fact, the values of $g_0$ and $g_1$ are different because they depend on the particle phase function, which cannot be measured remotely. The values of these
two parameters have to be estimated before being used in semi-analytical algorithms. Lee [9] used the averaged \(g_0\) and \(g_1\) values, which can be applied to coastal and open ocean waters. However, the values of \(g_0\) and \(g_1\) have a minimal influence on the inversion accuracy of the total absorption coefficient. Therefore, in this study, after trying to apply different values, we used the values of \(g_0\) of 0.08945 and \(g_1\) of 0.1247 as in the QAA original algorithm, which is suitable for more types of waters.

### 3.1.2. Reference Wavelength

The measurements of absorption coefficients of water constituents include \(a_{ph}(\lambda)\), \(a_d(\lambda)\), and \(a_g(\lambda)\). The total absorption coefficient \(a(\lambda)\) is the sum of \(a_{ph}(\lambda)\), \(a_d(\lambda)\), \(a_g(\lambda)\), and the absorption coefficient of pure water \(a_w(\lambda)\) [42].

\[
a(\lambda) = a_{ph}(\lambda) + a_d(\lambda) + a_g(\lambda) + a_w(\lambda)
\]  

(3)

The principle of selecting the reference wavelength in Step 2 (QAA) is that the absorption coefficient of pure water is dominant at the reference wavelength, and a \(\lambda_0\) of 0 around 700 nm [43,44]. In our study, on the basis of the center wavelengths of MODIS bands, three reference wavelengths (645, 678, and 748 nm) were used to derive the total absorption coefficients of three different samples (Figure 3), which represent three kinds of water, namely, turbid, eutrophic, and general water. The turbid water has high SPM concentration (SPM concentration = 93 mg/L), the eutrophic water has high Chl \(a\) concentration (Chl \(a\) concentration = 183.39 \(\mu\)g/L) and the SPM and Chl \(a\) concentrations of general water are not high (SPM concentration = 27 mg/L, Chl \(a\) concentration = 17.04 \(\mu\)g/L). As the graphs suggest, in the case of using 748 nm as reference wavelength, the derived total absorption coefficients are much closer to the measured total absorption coefficients. We can conclude that, regardless of the type of water, setting 748 nm as the reference wavelength is most suitable for Lake Chaohu.

### Table 1. Reference wavelengths from different cases of waters.

| Reference Wavelength | Areas                        | Reference |
|----------------------|------------------------------|-----------|
| 555 nm               | oligotrophic waters          | [9]       |
| 640 nm               | mesotrophic waters           | [9]       |
| 695 nm               | high-absorbing waters        | [17]      |
| 715 nm               | Lake Taihu, Chaohu           | [15,43]   |

According to the basic water quality in Lake Chaohu, \(a_w\) increases and \(a_g\) and \(a_{ph}\) tend to decrease to 0 around 700 nm. Therefore, the reference wavelengths should be around 700 nm [43,44]. In our study, on the basis of the center wavelengths of MODIS bands, three reference wavelengths (645, 678, and 748 nm) were used to derive the total absorption coefficients of three different samples (Figure 3), which represent three kinds of water, namely, turbid, eutrophic, and general water. The turbid water has high SPM concentration (SPM concentration = 93 mg/L), the eutrophic water has high Chl \(a\) concentration (Chl \(a\) concentration = 183.39 \(\mu\)g/L) and the SPM and Chl \(a\) concentrations of general water are not high (SPM concentration = 27 mg/L, Chl \(a\) concentration = 17.04 \(\mu\)g/L). As the graphs suggest, in the case of using 748 nm as reference wavelength, the derived total absorption coefficients are much closer to the measured total absorption coefficients. We can conclude that, regardless of the type of water, setting 748 nm as the reference wavelength is most suitable for Lake Chaohu.

Figure 3. Cont.
We found out that a very good correlation did not exist between the ratio of $R_{rs}$ and $Y$. The $Y$ value is related to parameters, such as $R_{rs}$, and concentrations of water compositions. First, we found out that a very good correlation did not exist between the ratio of $R_{rs}$ and $Y$ by applying measured data of Lake Chaohu. Thus, the relationships between the reference $Y$ value and certain water quality parameters were established (Figure 5). As the graphs show, the relationship between SPM...
concentration and Y value had the best correlation. Therefore, this model \( Y = 0.0103 \times SPM + 1.6386 \) \((N = 80)\) was used in our algorithm.

![Figure 4](image_url)

**Figure 4.** Comparison of measured total absorption coefficients with derived values of different Y values in the cases of (a) turbid, (b) eutrophic, and (c) general water.

Even though the relationship between the Y value and SPM is modeled, water quality parameters cannot be determined from previous calculations. Thus, the model of SPM concentration and \( R_{rs} \) should be built. Based on several references, the general characteristics of SPM inversion algorithms are presented in Table 3. In this study, similar methods were used to construct the relationship between \( R_{rs} \) and SPM concentration. We found that SPM concentration and \( R_{rs}(555)/R_{rs}(748) \) had the best correlation (Figure 6).

| Models | Areas | Reference |
|--------|-------|-----------|
| SPM = −1.91 + 1140.25 * \( R_{rs}(645) \) | Biloxi Bay | [47] |
| SPM = 9.65 * exp(58.81 * \( R_{rs}(645) \)) | Lake Taihu | [48] |
| \( \ln(SPM) = (R_{rs}(840)/R_{rs}(545) + 0.9614)/0.3193 \) | Gironde | [49] |
| SPM = 349.83 * \( R_{rs}(645) \) + 2.9663 | Muuga Port | [50] |
3.2. Decomposition of Total Absorption Coefficient

Deriving $a_{ph}(\lambda)$ and the absorption coefficients of gelbstoff and non-algal particulates ($a_{dg}(\lambda)$) from the total absorption coefficients ($a(\lambda)$) is a major challenge because the total absorption coefficient is the sum of $a_w$, $a_{ph}$, $a_d$, and $a_g$. Lee has developed an empirical algorithm for the separation [9].
We should estimate two parameters first: $\zeta$, which is equal to $a_{ph}(410)/a_{ph}(440)$, and $\xi$, which amounts to $a_{dg}(410)/a_{dg}(440)$. The value of $\zeta$ is obtained using the ratio of measured $r_{rs}(440)/r_{rs}(555)$ data in the QAA algorithm.

### 3.2.1. The Value of Spectral Slope of $a_{dg}$ Spectrum (S)

The spectral slope of $a_{dg}$ spectrum (S) can depict the spectral shape of $a_{dg}(\lambda)$, which is the sum of $a_g(\lambda)$ and $a_d(\lambda)$. In the original QAA process, $S$ was valued at 0.015 nm$^{-1}$. The measured data of $a_{dg}(410)$ and $a_{dg}(440)$ in Lake Chaohu were used to calculate $S$. We concluded that the average value of $S$ is 0.01453, and the standard deviation is 0.001129, which means that all the values are basically distributed around the average. Therefore, we selected the mean, 0.01453, as the value of $S$ in our study.

### 3.2.2. The Relationship of $a_{ph}$ and $r_{rs}$

The value of $a_{ph}(410)/a_{ph}(440)$ is calculated from the ratio of $r_{rs}(440)/r_{rs}(555)$ through an empirical formula in the original QAA algorithm [9]. Considering the research area, we had to rebuild the relationship between $a_{ph}$ and $r_{rs}$ by simulating the relationship between the $a_{ph}(410)/a_{ph}(440)$ and the spectral ratio $r_{rs}$ of the center wavelengths of MODIS bands between 400 and 800 nm. The model was constructed using $r_{rs}(645)/r_{rs}(678)$ with a high correlation, as shown in Figure 7.

**Figure 7.** Model of relationship of below-surface remote sensing reflectance $r_{rs}(645)/r_{rs}(678)$ with absorption coefficients of phytoplankton $a_{ph}(410)/a_{ph}(440)$.

The specific calculation process of this improved QAA is as follows (Table 4).

To evaluate the performance of this algorithm and the accuracy of the MOD09 data after correction, three parameters were calculated.

The accuracy evaluation indicators used in this study include average relative error (MRE) [51], average absolute error (MAE) and root mean square error (RMSE) [52]. The expression equations are as follows:

\[
\text{MRE} = \frac{1}{N} \sum_{i=1}^{N} \left| \frac{y_i - x_i}{x_i} \right|
\]

\[
\text{MAE} = \frac{1}{N} \sum_{i=1}^{N} \left| y_i - x_i \right|
\]

\[
\text{RMSE} = \sqrt{\frac{1}{N} \sum_{i=1}^{N} (y_i - x_i)^2}
\]
where x represents the measured value, y represents the derived value, and N represents the number of samples. Coefficient of determination ($R^2$) was also used to assess the accuracy of the model.

Table 4. Steps of the improved quasi-analytical algorithm (QAA).

| Step | Formula | Approach |
|------|---------|----------|
| 0    | $r_n = R_{rs}/(0.52 + 1.7R_{rs})$ | Semi-analytical |
| 1    | $u(\lambda) = \frac{x - \xi}{\varphi + (\phi + 4\varphi^2)}$ | Semi-analytical |
| 2    | $a(748) = a_{0}(748)$ | Empirical |
| 3    | $b_{bp}(748) = \frac{a(748)}{\varphi + (\phi + 4\varphi^2)} - b_{bp}(748)$ | Analytical |
| 4    | $Y = 0.0103 \times \exp[(0.0121(R_{rs}(555)/R_{rs}(748))^2 - 0.3452(R_{rs}(555)/R_{rs}(748)) + 4.7784] + 1.6386$ | Empirical |
| 5    | $b_{bp}(\lambda) = b_{bp}(748)\left[\frac{\lambda}{748}\right]^\lambda$ | Semi-analytical |
| 6    | $a(\lambda) = \frac{[1-a(\lambda)]\beta_{bp}(\lambda) + \beta_{bp}(\lambda)}{\beta_{bp}(\lambda)}$ | Analytical |
| 7    | $\xi = \frac{a_{0}(410) - a_{0}(440)}{\beta_{bp}(440)}$ | Empirical |
| 8    | $\xi = \frac{a_{0}(440) - a_{0}(410)}{\beta_{bp}(440)}$ | Semi-analytical |
| 9    | $a_{bp}(440) = a(440) - a_{dp}(440) - a_{dp}(440)$ | Analytical |
| 10   | $a_{bp}(440) = a(440) - a_{dp}(440)$ | Analytical |

4. Results and Validation

4.1. MODIS Corrected Data Accuracy Evaluation

Compared with the measured $R_{rs}$ data, the errors of the $R_{rs}$ derived from MOD09 product were evaluated in this paper. Before correction, as shown in Figure 8a, most of the 79 points of $R_{rs}$ were above the 1:1 line, indicating that, on the same scale, the data at 413, 443, 469, 555, 645, 678, and 748 nm were generally larger than the measured data; after using this correction method, as shown in Figure 8b, the $R_{rs}$ of the points generally had a good linear correlation. The scatterplots were mostly distributed near the 1:1 line. At the wavelength 748 nm, the corrected values were still a little higher above the 1:1 line, indicating that, on the same scale, the data at 413, 443, 469, 555, 645, 678, and 748 nm were generally larger than the measured data; after using this correction method, as shown in Figure 8b, the $R_{rs}$ of the points generally had a good linear correlation. The scatterplots were mostly distributed near the 1:1 line. At the wavelength 748 nm, the corrected values were still a little higher than the measured data. Tables 5 and 6 show the statistics of the errors before and after correction. The MRE at 413 nm was reduced from 76.46% to 30.02%, and the RMSE was from 0.012 sr$^{-1}$ to 0.005 sr$^{-1}$. The MRE value before correction at the 555-nm band was 13.83%, while the MRE value after correction was only 9.23%. The MRE of 748 nm before correction was as high as 84.66%, while the MRE after correction was 30.02%, and the RMSE was from 0.012 sr$^{-1}$ to 0.005 sr$^{-1}$. Compared with the original MOD09, the RMSEs and MREs of the corrected MOD09 at all bands were significantly reduced. This shows that the correction method we used in this study can obtain more accurate $R_{rs}$.

Figure 8. Scatterplots of $R_{rs}$ derived from (a) original and (b) corrected MOD09 compared with measurements in different bands.
Table 5. Error statistics of \( R_{rs} \) derived from the original MOD09.

| Wavelength (nm) | MRE (%) | RMSE (sr\(^{-1}\)) |
|-----------------|---------|---------------------|
| 413             | 76.46   | 0.012               |
| 443             | 68.35   | 0.012               |
| 555             | 13.83   | 0.005               |

4.2. Inversion of Absorption Coefficients in Different Water Types

The measured data of \( R_{rs} \) of Lake Chaohu were applied to this model to obtain absorption coefficients. The wavelengths of input \( R_{rs} \) were at center wavelengths of MODIS bands between 400 and 700 nm, including 413, 443, 469, 488, 531, 551, 555, 645, 667, and 678 nm. The retrieved IOPs included \( a_{ph}(\lambda) \) and \( a_{dg}(\lambda) \) of these wavelengths. Figure 9 shows the comparison of retrieved and measured \( a_{ph} \) and \( a_{dg} \) of the three different types of water. The concentrations of SPM and Chl \( a \) are shown in the graphs.

Figure 9. Cont.
Figure 9. Comparison of derived and measured $a_{ph}$ and $a_{dg}$ of three different types of water: (a)/(b) turbid water, (c)/(d) eutrophic water, and (e)/(f) general water.

As shown in Figure 9, this model tends to be more suitable for general waters as it is more effective in obtaining $a_{ph}$ when applied to general water than eutrophic water. The values of obtained $a_{dg}$ are closer to those of measured $a_{dg}$ than $a_{ph}$. Thus, the accuracy of derived $a_{ph}$ in all water conditions needs to be improved especially in the case of turbid waters.

4.3. Derived Values at Typical Wavelengths

To present a general description of the performance of this algorithm, we used 25 field-measured test samples to derive $a(\lambda)$, $a_{ph}(\lambda)$, and $a_{dg}(\lambda)$ at 410 nm, 440 nm, and center wavelengths of MODIS bands between 400 and 700 nm, then compared them with measured data. Table 7, Figures 10 and 11 show the results of this analysis.

| Values | MRE (%) | RMSE (sr⁻¹) |
|--------|---------|-------------|
| $a(\lambda)$ | 18.96 | 0.88 |
| $a_{ph}(\lambda)$ | 102.04 | 0.52 |
| $a_{dg}(\lambda)$ | 30.33 | 1.09 |

Figure 10 shows the total absorption coefficients of typical wavelengths such as 440, 488, and 555 nm.

Figure 10. Comparison of improved QAA-derived total absorption coefficients $a(\lambda)$ versus the measured total absorption coefficients $a(\lambda)$ for wavelengths at 440, 488, and 555 nm.
5. Discussion

5.1. Error Propagation

Error propagation means errors that may occur at each step have varying effects on the analysis results. The errors in each step propagate to the next step in the step-by-step process. We analyzed the error propagation of some steps of this algorithm by using modeling data (Table 8). This part shows the performance assessment of absorption coefficients at wavelengths 410, 440 nm, and the center wavelengths of MODIS bands between 400 and 700 nm.
shows the performance assessment of absorption coefficients at wavelengths 410, 440 nm, and the center wavelengths of MODIS bands between 400 and 700 nm.

| Step | Formulas | Approach | Relative Errors Range | MRE | RMSE (sr⁻¹) |
|------|----------|----------|------------------------|-----|-------------|
| 2    | $\alpha(748) = \alpha_0(748)$ | Empirical | $-14.26\%$ | $3.68\%$ | $0.12$ |
| 4    | $Y = 0.0103*\exp[0.0121(R_\text{rs}(555)/R_\text{rs}(748))^2 - 0.3452(R_\text{rs}(555)/R_\text{rs}(748)) + 4.7784] + 1.6386$ | Empirical | $-34.14\%$ | $19.31\%$ | $0.72$ |
| 7    | $\xi = \frac{\alpha(410)}{\alpha(440)} = \frac{2.896}{r_s(445)/r_s(678)} - 1.2933$ | Empirical | $-25.91\%$ | $12.62\%$ | $0.15$ |
| 8    | $\xi = \frac{\alpha(410)}{\alpha(440)} = \exp[S(440 - 410)]$ | Semi-analytical | $-8.19\%$ | $2.74\%$ | $0.05$ |
|      | $\alpha_{dg}$ | Empirical | $28.25\%$ | $35.07\%$ | $1.22$ |
|      | $\alpha_{dg}$ | Semi-analytical | $133.10\%$ | $133.10\%$ | $1.22$ |
|      | $\alpha_{ph}$ | Semi-analytical | $14.26\%$ | $46.19\%$ | $0.12$ |

As the table suggests, all the errors were from the empirical and semi-analytical algorithms. Through the steps to retrieve the total absorption coefficients, the MRE between calculated Y values and reference Y values was approximately $19.31\%$, which was due to the relationship of $R_{\text{rs}}$, SPM concentration, and the value of Y. Therefore, this step consequently led to the errors of the calculated total absorption. The retrieval of $\alpha_{ph}(410)/\alpha_{ph}(440)$ and $\alpha_{dg}(410)/\alpha_{dg}(440)$ had errors of $12.62\%$ and $2.74\%$, respectively, which showed that the main source of the errors of $\alpha_{dg}$ was due to the calculation of $a_{ph}$ and then extended to $a_{dg}$ in the full wavelength range. Also, the errors of derived total absorption coefficients affected the accuracy of $a_{ph}$ and $a_{dg}$. At the same time, because the values of measured $a_{ph}$ at longer wavelengths and some samples were small, the MREs increased, thereby influencing the total MRE of $a_{ph}$.

5.2. Comparison with QAA

As mentioned, QAA did not function well when applied to Lake Chaohu (Figure 12). In the case below, especially at a wavelength longer than 600 nm, the values of $a_{ph}$ are almost less than zero, which was impossible for Lake Chaohu. Therefore, improving this algorithm is necessary.

![Figure 12](image-url)  
**Figure 12.** Comparison of QAA-retrieved $a_{ph}$ versus measured data and the improved QAA-retrieved a ($a_{ph}$) versus measured data.

The algorithm in this article was further validated by the measured dataset collected in Lake Chaohu. The version, QAA_v6, tended to be more suitable for turbid coastal waters, so it was also applied to the same dataset (Figure 13). The assessment results for retrieved absorption coefficients at some special wavelengths are summarized in Table 9. The RMSEs and MREs for the algorithm in this study were in the range of 0.21–1.06 sr⁻¹ and 17.27–54.85%, while those of QAA_v6 were 0.99–4.17 sr⁻¹...
and 56.93–73.51%, respectively. Specifically, the RMSEs and MREs of the QAA_v6 were larger than those of the algorithm in this study. The values of total absorption coefficients derived from QAA_v6 were much smaller than measured data. The larger RMSEs' and MREs' values derived from QAA_v6 were mainly because of a short reference wavelength and inappropriate estimated formulas that do not work for turbid Case 2 waters. The \( a_{\text{ph}}(443) \) was also retrieved based on QAA_v6 for comparison. Scatterplots of derived and measured \( a_{\text{ph}}(443) \) are shown in Figure 13, and the evaluation indices are also demonstrated in Table 9. In general, we can conclude that the algorithm in this research had smaller errors of RMSE and MRE of 0.60 sr\(^{-1}\) and 54.85%, respectively, compared with those of 1.46 sr\(^{-1}\) and 56.93% from the \( a_{\text{ph}}(443) \) estimated by QAA_v6. However, because the \( a_{\text{ph}} \) derived from the algorithm in this study tended to be larger than measured data, at some points, \( a_{\text{ph}}(443) \) derived from QAA-v6 were closer to measured data than those of this study.

![Figure 12](image)

**Figure 12.** Comparison of QAA-retrieved \( a \) (\( a_{\text{ph}} \)) versus measured data and the improved QAA-retrieved \( a \) (\( a_{\text{ph}} \)) versus measured data.

The algorithm in this article was further validated by the measured dataset collected in Lake Chaohu. The version, QAA_v6, tended to be more suitable for turbid coastal waters, so it was also applied to the same dataset (Figure 13). The assessment results for retrieved absorption coefficients at some special wavelengths are summarized in Table 9. The RMSEs and MREs for the algorithm in this study were in the range of 0.21–1.06 sr\(^{-1}\) and 17.27%–54.85%, while those of QAA_v6 were 0.99–4.17 sr\(^{-1}\) and 56.93%–73.51%, respectively. Specifically, the RMSEs and MREs of the QAA_v6 were larger than those of the algorithm in this study. The values of total absorption coefficients derived from QAA_v6 were much smaller than measured data. The larger RMSEs' and MREs' values derived from QAA_v6 were mainly because of a short reference wavelength and inappropriate estimated formulas that do not work for turbid Case 2 waters. The \( a_{\text{ph}}(443) \) was also retrieved based on QAA_v6 for comparison. Scatterplots of derived and measured \( a_{\text{ph}}(443) \) are shown in Figure 13, and the evaluation indices are also demonstrated in Table 9. In general, we can conclude that the algorithm in this research had smaller errors of RMSE and MRE of 0.60 sr\(^{-1}\) and 54.85%, respectively, compared with those of 1.46 sr\(^{-1}\) and 56.93% from the \( a_{\text{ph}}(443) \) estimated by QAA_v6. However, because the \( a_{\text{ph}} \) derived from the algorithm in this study tended to be larger than measured data, at some points, \( a_{\text{ph}}(443) \) derived from QAA-v6 were closer to measured data than those of this study.

**Figure 13.** Cont.
Figure 13. Comparison of measured and derived total absorption coefficients at (a) 443 nm and (b) 555 nm, and a_{ph} at (c) 443 nm for applying the algorithm in this study and QAA_v6, respectively.

Table 9. Accuracy assessment of the algorithm in this study and QAA_v6.

| Algorithms | N  | MRE     | R^2  | RMSE (sr^{-1}) |
|------------|----|---------|------|-----------------|
| a(443)     |    |         |      |                 |
| this study | 25 | 17.27%  | 0.75 | 1.06            |
| QAA_v6     | 25 | 73.51%  | 0.43 | 4.17            |
| a(555)     |    |         |      |                 |
| this study | 25 | 18.71%  | 0.88 | 0.21            |
| QAA_v6     | 25 | 57.72%  | 0.37 | 0.99            |
| a_{ph}(443)|    |         |      |                 |
| this study | 25 | 54.85%  | 0.76 | 0.60            |
| QAA_v6     | 25 | 56.93%  | 0.60 | 1.46            |

5.3. MODIS Data Inversion

We used the algorithm proposed in this study to calculate the a_{ph} at 443, 645, and 678 nm of Lake Chaohu in 2013 by applying corrected MOD09 data (Figure 14). Because of the difference of bands, we used MODIS bands 8 and 9 data to be the input parameters at 410 and 440 nm. The missing parts of the image were due to saturation that usually occurs at long wavelengths of 1-km resolution of this product. Even though there were some problems with this product, we still could verify the general seasonal changes of Lake Chaohu. Generally, a_{ph} varied largely in Lake Chaohu. High a_{ph} was observed in the northwestern parts of Lake Chaohu in the summer and autumn, and a_{ph} were relatively lower in the spring and winter. This pattern is consistent with the known phenomenon. Cyanobacteria blooms occur mainly in the western area in the summer, and the large amount of cyanobacteria in the western part is due to the exogenous load of the lakes mainly from the northwest of the basin. The suitable temperature of 20–34 °C in summer, the higher N and P concentrations, the higher PH value, the appropriate light intensity, and other environmental conditions provide the perfect environment for the growth of cyanobacteria. Therefore, a_{ph} tends to be higher in the western part in summer.
6. Conclusions

Based on the field-measured data of Lake Chaohu, this study improved the QAA algorithm to provide an effective inversion of the IOPs of Lake Chaohu according to MODIS bands. The appropriate reference wavelength was shifted to 748 nm according to the measured data from the lake, and the applicable empirical model of the Y value was established by building models with SPM concentration and Rs. The $a_{dg}$ and $a_{ph}$ were also derived by changing important parameters according to Lake Chaohu. To test the accuracy of this model, we applied this algorithm to a test dataset. This algorithm tends to be more suitable for general waters. It works better in the retrieval of total absorption coefficients in the condition of Lake Chaohu than original QAA and QAA_v6 do. The derived $a_{dg}$ of this algorithm tend to be smaller than measured data and the derived $a_{ph}$ tend to be bigger than measured values at some points. We also used the corrected MOD09 data to calculate $a_{ph}$ at 443, 645, and 678 nm by the model proposed in this study. It shows that, in summer and autumn, $a_{ph}$ tend to be higher in the northwestern part of Lake Chaohu, which is similar to the previous studies.

More independent tests with field measurement are required for validating and improving the algorithm. This algorithm needs to be improved in several aspects. First, the accuracy of the empirical model for calculating the Y value can be developed because it is one of the errors of the derived total absorption coefficients. Secondly, basic wavelengths can be changed to derive accurate $a_{ph}$ and $a_{dg}$. 
Combining the measured backscattering coefficients with the derived backscattering coefficients in future research will help improve the accuracy of this algorithm.
