Generic Consequences of a Supersymmetric U(1) Gauge Factor at the TeV Scale

E. Keith and Ernest Ma

Department of Physics, University of California, Riverside, CA 92521, USA

Abstract

We consider an arbitrary supersymmetric U(1) gauge factor at the TeV scale, under which the two Higgs superfields $H_{1,2}$ of the standard model are nontrivial. We assume that there is a singlet superfield $S$ such that $H_1 H_2 S$ is an allowed term in the superpotential. We discuss first the generic consequences of this hypothesis on the structure of the two-doublet Higgs sector at the electroweak energy scale, as well as $Z - Z'$ mixing and the neutralino sector. We then assume the existence of a grand unified symmetry and universal soft supersymmetry breaking terms at that scale. We further assume that the additional U(1) is broken radiatively via a superpotential term of the form $hh^c S$, where $h$ and $h^c$ are exotic color-triplet fields which appear in $E_6$ models. We show that the U(1) breaking scale and the parameter $\tan \beta \equiv v_2/v_1$ are then both predicted as functions of the $H_1 H_2 S$ coupling.
1 Introduction

If supersymmetry is broken at the TeV energy scale and the standard \( SU(3)_C \times SU(2)_L \times U(1)_Y \) gauge symmetry is not extended at that same scale, then the existence of supersymmetry above that scale protects the theory from nondecoupling contributions of physics above that scale. In other words, we get the Minimal Supersymmetric Standard Model (MSSM). However, if the gauge symmetry is extended also at the TeV energy scale and it breaks down to that of the standard model together with the supersymmetry, there will be in general new important phenomenological consequences at the TeV scale as well as the 100 GeV scale. With further simplifying assumptions, the parameters of the two scales may also be related.

A particularly interesting extension of the MSSM is the inclusion of an extra \( U(1) \) factor at the TeV energy scale. The motivation for this could be theoretical. If the standard model is embedded in a larger symmetry group of rank greater than 4, such as \( SO(10) \) [rank 5] or \( E_6 \) [rank 6], then an extra \( U(1) \) gauge factor is very possible at the TeV energy scale. This is especially true for the supersymmetric \( E_6 \) model\(^1\)\(^2\) based on the \( E_8 \times E_8 \) heterotic string. In particular, if only flux loops are invoked to break \( E_6 \) down to \( SU(3)_C \times SU(2)_L \times U(1)_Y \), then a specific extra \( U(1) \) [conventionally known as \( U(1)_\eta \)] is obtained. Remarkably, \( U(1)_\eta \) is also phenomenologically implicated\(^3\) by the experimental \( R_b \equiv \Gamma(Z \rightarrow b\bar{b})/\Gamma(Z \rightarrow \text{hadrons}) \) excess. Another possible clue is the totality of neutrino-oscillation experiments (solar, atmospheric, and laboratory) which suggest that there are at least 4 neutrinos. This has been shown\(^4\) to have a natural explanation in terms of the \( E_6 \) superstring model with a specific \( U(1) \) called \( U(1)_N \).

In Sec. 2, we consider a generic extra supersymmetric \( U(1) \) gauge factor at the TeV energy scale with two doublet superfields \( H_{1,2} \) and a singlet superfield \( S \) such that \( H_1 H_2 S \) is an allowed term in the superpotential. (Note that if \( S \) has a nonzero charge under the
additional U(1), as is the case if the scalar component of S is to acquire a nonzero vacuum expectation value (VEV) so as to break this U(1), then above this breaking scale, no $\mu H_1H_2$ superpotential term exists.) We then derive its nondecoupling effects on the two-doublet Higgs sector at the 100 GeV scale. In Sec. 3, we specialize to a class of $U(1)_{\alpha}$ models derivable from $E_6$, of which the $U(1)_\eta$ and $U(1)_N$ models are special cases. In Sec. 4, we discuss how the new $Z'$ mixes with the standard Z in the general case, and formulate the effects in terms of the oblique parameters $\epsilon_{1,2,3}$ or $S,T,U$ in the $U(1)_\alpha$ models. We also discuss the generic neutralino sector. In Sec. 5, we show how supersymmetric scalar masses are affected by the extra D-terms from $U(1)_\alpha$. Combining this with the results of Sec. 2 and Sec. 3, and assuming universal soft supersymmetry breaking terms at the grand-unification scale, we show that there is a relationship between the $U(1)_{\alpha}$ vacuum expectation value and the well-known parameter $\tan \beta \equiv v_2/v_1$ used in the MSSM. Finally in Sec. 6, we have some concluding remarks.

2 Tree-Level Nondecoupling at the 100 GeV Scale

As the U(1) gauge factor is broken together with the supersymmetry at the TeV scale, the resulting heavy scalar particles have nondecoupling contributions to the interactions of the light scalar particles.[5] Consequently, the two-doublet Higgs structure is of a more general form than that of the Minimal Supersymmetric Standard Model (MSSM). Previous specific examples have been given.[6, 7, 8] Here we present the most general analysis. We denote the scalar components of $H_1$, $H_2$, and $S$ as $\tilde{\Phi}_1$, $\Phi_2$, and $\chi$ respectively. Under $SU(3)_C \times SU(2)_L \times U(1)_Y \times U(1)_X$, we then have

$$
\tilde{\Phi}_1 = \begin{pmatrix} \phi^0_1 \\ -\phi^-_1 \end{pmatrix} \sim (1, 2, -\frac{1}{2}; -a),
$$

(1)
\[ \Phi_2 = \begin{pmatrix} \phi_2^+ \\ \phi_2^0 \end{pmatrix} \sim (1, 2, \frac{1}{2}; -1 + a), \quad (2) \]
\[ \chi = \chi^0 \sim (1, 1, 0; 1), \quad (3) \]

where each last entry is the arbitrary assignment of that scalar multiplet under the extra \( U(1)_X \) with coupling \( g_x \), assuming of course that the superpotential has the term \( fH_1H_2S \).

The corresponding scalar potential contains thus

\[ V_F = f^2[(\Phi_1^\dagger \Phi_2)(\Phi_2^\dagger \Phi_1) + (\Phi_1^\dagger \Phi_1 + \Phi_2^\dagger \Phi_2)\bar{\chi}\chi], \quad (4) \]

and from the gauge interactions,

\[ V_D = \frac{1}{8}g_1^2[(\Phi_1^\dagger \Phi_1)^2 + (\Phi_2^\dagger \Phi_2)^2 + 2(\Phi_1^\dagger \Phi_1)(\Phi_2^\dagger \Phi_2) - 4(\Phi_1^\dagger \Phi_2)(\Phi_2^\dagger \Phi_1)] \]
\[ + \frac{1}{8}g_1^2[-\Phi_1^\dagger \Phi_1 + \Phi_2^\dagger \Phi_2]^2 \]
\[ + \frac{1}{2}g_x^2[-a\Phi_1^\dagger \Phi_1 - (1 - a)\Phi_2^\dagger \Phi_2 + \bar{\chi}\chi]^2. \quad (5) \]

Let \( \langle \chi \rangle = u \), then \( \sqrt{2}\text{Re}\chi \) is a physical scalar boson with \( m^2 = 2g_x^2u^2 \), and the \((\Phi_1^\dagger \Phi_1)\sqrt{2}\text{Re}\chi \)

coupling is \( \sqrt{2}u(f^2 - g_x^2a) \). Hence the effective \((\Phi_1^\dagger \Phi_1)^2 \)
coupling \( \lambda_1 \) is given by

\[ \lambda_1 = \frac{1}{4}(g_1^2 + g_2^2) + g_x^2a^2 - \frac{2(f^2 - g_x^2a)^2}{2g_x^2} \]
\[ = \frac{1}{4}(g_1^2 + g_2^2) + 2af^2 - \frac{f^4}{g_x^2}. \quad (6) \]

Similarly,

\[ \lambda_2 = \frac{1}{4}(g_1^2 + g_2^2) + 2(1 - a)f^2 - \frac{f^4}{g_x^2}, \quad (7) \]
\[ \lambda_3 = -\frac{1}{4}g_1^2 + \frac{1}{4}g_2^2 + f^2 - \frac{f^4}{g_x^2}, \quad (8) \]
\[ \lambda_4 = -\frac{1}{2}g_2^2 + f^2, \quad (9) \]

where the two-doublet Higgs potential has the generic form

\[ V = m_1^2\Phi_1^\dagger \Phi_1 + m_2^2\Phi_2^\dagger \Phi_2 + m_{12}(\Phi_1^\dagger \Phi_2 + \Phi_2^\dagger \Phi_1) + \frac{1}{2}\lambda_1(\Phi_1^\dagger \Phi_1)^2 \]
\[ + \frac{1}{2}\lambda_2(\Phi_2^\dagger \Phi_2)^2 + \lambda_3(\Phi_1^\dagger \Phi_1)(\Phi_2^\dagger \Phi_2) + \lambda_4(\Phi_1^\dagger \Phi_2)(\Phi_2^\dagger \Phi_1). \quad (10) \]
From Eqs. (6) to (9), it is clear that the MSSM is recovered in the limit \( f = 0 \). [Note that \( m_{12}^2 \neq 0 \) only after U(1) symmetry breaking and it would be proportional to \( f \) if universal soft supersymmetry breaking is assumed.] Let \( \langle \phi^0_{1,2} \rangle \equiv v_{1,2}, \tan \beta \equiv v_2/v_1, \) and \( v^2 \equiv v_1^2 + v_2^2 \), then this \( V \) has an upper bound on the lighter of the two neutral scalar bosons given by

\[
(m^2_h)_{\text{max}} = 2v^2[\lambda_1 \cos^4 \beta + \lambda_2 \sin^4 \beta + 2(\lambda_3 + \lambda_4) \sin^2 \beta \cos^2 \beta] + \epsilon, \tag{11}
\]

where we have added the radiative correction\[9\] due to the \( t \) quark and its supersymmetric scalar partners, \( \epsilon = \frac{3g_2^2m_t^4}{8\pi^2M_W^2} \ln \left( 1 + \frac{\tilde{m}^2}{m_t^2} \right). \tag{12} \)

We note also that the soft supersymmetry-breaking term \( fA_f \Phi_1^\dagger \Phi_2 \chi + \text{h.c.} \) (from which we obtain \( m_{12}^2 = fA_f u \)) also contributes to \( \lambda_4 \) and generates some additional quartic scalar couplings. However, we assume here that \( fA_f/g_x^2 u \) is small, because we are mainly interested in the case where the electroweak Higgs sector has two relatively light doublets and not just one light doublet. Using Eqs. (6) to (9), we obtain

\[
(m^2_h)_{\text{max}} = M_Z^2 \cos^2 2\beta + \epsilon + \frac{f^2}{\sqrt{2}G_F} \left[ A - \frac{f^2}{g_x^2} \right], \tag{13}
\]

where

\[
A = \frac{3}{2} + (2a - 1) \cos 2\beta - \frac{1}{2} \cos^2 2\beta. \tag{14}
\]

If \( A > 0 \), then the MSSM bound can be exceeded. However, \( f^2 \) is still constrained from the requirement that \( V \) be bounded from below. We note here that although \( V_F \) of Eq. (4) and \( V_D \) of Eq. (5) are nonnegative for any value of \( f \), \( V \) of Eq. (10) is not automatically bounded from below. This simply means that if \( f \) is too large, the minimum of the original potential only breaks the extra U(1) but not the electroweak gauge symmetry. Given \( g_x \) and \( a \), we can vary \( \cos 2\beta \) and \( f \) to find the largest numerical value of \( m_h \). We show in Fig. 1 this upper bound on \( m_h \) as a function of \( g_x^2 \) for several specific values of \( a \). The value \( a_0 \) is chosen in the top curve to maximize \( m_h \) for a given value of \( g_x^2 \). This upper bound increases as \( g_x^2 \)
increases. However, it is reasonable to assume that \( g_x \) cannot be too large. In fact, in the specific models to be discussed in the next section, \( g_x^2 < 0.16 \). As shown in Fig. 1, even for \( g_x^2 = 0.5 \), the upper bound is only about 190 GeV.

It should be mentioned that an upper bound on \( m_h \) has been previously obtained\cite{10} assuming that there is no extra U(1) at the supersymmetry-breaking scale. However, the same proof also goes through with an extra U(1). We improve on Ref.\cite{10} in this case by computing exactly how the off-diagonal nondecoupling terms affect the upper bound on \( m_h \), resulting in Fig. 1 as shown. If \( f A_f / g_x^2 u \) is not small as we have assumed, then the reduction to \( V \) of Eq. (10) is not valid. In this case, the electroweak Higgs sector consists of effectively only one Higgs doublet with \( m_h \) bounded by a function which involves also \( A_f \).\cite{11}

3 \ U(1) Gauge Factor from E(6)

As already mentioned in the Introduction, an extra supersymmetric U(1) gauge factor at the TeV scale is a very viable possibility from the spontaneous breakdown of \( E_6 \). Consider the following sequential reduction:

\[
E_6 \rightarrow SO(10) \ [\times U(1)_{\psi}] \tag{15}
\]

\[
SO(10) \rightarrow SU(5) \ [\times U(1)_{\chi}] \tag{16}
\]

\[
SU(5) \rightarrow SU(3)_C \times SU(2)_L \ [\times U(1)_Y]. \tag{17}
\]

At each step, a U(1) gauge factor may or may not appear, depending on the details of the symmetry breaking. Assuming that a single extra U(1) survives down to the TeV energy scale, then it is generally given by a linear combination of \( U(1)_\psi \) and \( U(1)_\chi \) which we will call \( U(1)_a \).

Under the maximal subgroup \( SU(3)_C \times SU(3)_L \times SU(3)_R \), the fundamental representation
of $E_a$ is given by

$$27 = (3, 3, 1) + (3^*, 1, 3^*) + (1, 3^*, 3).$$

(18)

Under the subgroup $SU(5) \times U(1)_\psi \times U(1)_\chi$, we then have

$$27 = (10; 1, -1) [(u, d), u^e, e^c]$$

$$+ (5^*; 1, 3) [d^c, (\nu_e, e)]$$

$$+ (1; 1, -5) [N]$$

$$+ (5; -2, 2) [h, (E^c, N^c_E)]$$

$$+ (5^*; -2, -2) [h^c, (\nu_E, E)]$$

$$+ (1; 4, 0) [S],$$

(19)

where the $U(1)$ charges refer to $2\sqrt{6}Q_\psi$ and $2\sqrt{10}Q_\chi$. Note that the known quarks and leptons are contained in $(10; 1, -1)$ and $(5^*; 1, 3)$, and the two Higgs scalar doublets are represented by $(\nu_E, E)$ and $(E^c, N^c_E)$. Let

$$Q_\alpha = Q_\psi \cos \alpha - Q_\chi \sin \alpha,$$

(20)

then the $\eta$-model\cite{1,2} is obtained with $\tan \alpha = \sqrt{3/5}$ and we have

$$27 = (10; 2) + (5^*; -1) + (1; 5)$$

$$+ (5; -4) + (5^*; -1) + (1; 5),$$

(21)

where $2\sqrt{15}Q_\eta$ is denoted; and the $N$-model\cite{4} is obtained with $\tan \alpha = -1/\sqrt{15}$ resulting in

$$27 = (10; 1) + (5^*; 2) + (1; 0)$$

$$+ (5; -2) + (5^*; -3) + (1; 5),$$

(22)

where $2\sqrt{10}Q_N$ is denoted. This model is so called because the superfield $N$ has $Q_N = 0$. It allows $S$ to be a naturally light singlet neutrino and is ideally suited to explain the totality
of all neutrino-oscillation experiments, i.e. solar\(^{12}\), atmospheric\(^{13}\), and laboratory\(^{14}\). It is also a natural consequence of an alternative \(SO(10)\) decomposition\(^{15}\) of \(E_6\), i.e.

\[
16 = [(u, d), u^c, e^c; h^c, (\nu_E, E); S],
\]

\[
10 = [h, (E^c, N^c_E); d^c, (\nu_e, e)],
\]

\[
1 = [N],
\]

which differs from the conventional assignment by how the \(SU(5)\) multiplets are embedded.

Identifying \(\tilde{\Phi}_1, \Phi_2,\) and \(\chi\) with the scalar components of \((\nu_E, E), (E^c, N^c_E),\) and \(S\) of which we can choose one copy of each via a discrete symmetry\(^{11}\) to be the ones with VEVs, we see that the general analysis of the previous section is applicable for this class of \(U(1)\)-extended models. (Of course, more than one copy of \((\nu_E, E), (E^c, N^c_E),\) or \(S\) could have VEVs but that would lead to a much less constrained scenario.) Assuming that \(U(1)_\alpha\) is normalized in the same way as \(U(1)_Y\), we find it to be a very good approximation\(^{8}\) to have \(g^2_\alpha = (5/3)g^2_1\). We then obtain for the \(\eta\)-model,

\[
g^2_\alpha = \frac{25}{36} g^2_1, \quad a = \frac{1}{5},
\]

and for the \(N\)-model,

\[
g^2_\alpha = \frac{25}{24} g^2_1, \quad a = \frac{3}{5},
\]

whereas in the exotic left-right model\(^{13,14}\),

\[
g^2_\alpha = \frac{(g^2_1 + g^2_2)(1 - \sin^2 \theta_W)^2}{4(1 - 2 \sin^2 \theta_W)}, \quad a = \tan^2 \theta_W.
\]

These three specific points have been singled out in Fig. 1. Furthermore, when we take the squark masses to be about 1 TeV we find the largest numerical value of \(m_h\) in the \(U(1)_\alpha\) models to be about 142 GeV , as compared to 128 GeV in the MSSM, and it is achieved with

\[
\tan \alpha = -\frac{2\sqrt{3/5} \cos 2\beta}{3 - \cos^2 2\beta},
\]

which is possible in the \(\eta\)-model, i.e. \(\tan \alpha = \sqrt{3/5}\) and \(\cos 2\beta = -1\).
4 Z - Z’ and Neutralino Sectors

The part of the Lagrangian containing the interaction of $\Phi_{1,2}$ and $\chi$ with the vector gauge bosons $A_i(i = 1, 2, 3)$, $B$, and $Z'$ belonging to the gauge factors $SU(2)_L$, $U(1)_Y$, and $U(1)_X$ respectively is given by

$$L = |(\partial^\mu - \frac{ig_2}{2} \tau_i A_i^\mu + \frac{ig_1}{2} B^\mu + ig_x a Z'^\mu)\tilde{\Phi}_1|^2$$
$$+ |(\partial^\mu - \frac{ig_2}{2} \tau_i A_i^\mu - \frac{ig_1}{2} B^\mu + ig_x (1-a) Z'^\mu)\Phi_2|^2$$
$$+ |(\partial^\mu - ig_x Z'^\mu)\chi|^2,$$

(30)

where $\tau_i$ are the usual $2 \times 2$ Pauli matrices. With the definition $Z \equiv (g_2 A_3 - g_1 B)/g_Z$, where $g_Z \equiv \sqrt{g_1^2 + g_2^2}$, the mass-squared matrix spanning $Z$ and $Z'$ is given by

$$M_{Z,Z'}^2 = \begin{bmatrix} (1/2)g_Z^2(v_1^2 + v_2^2) & g_Z g_x [-av_1^2 + (1-a)v_2^2] \\ g_Z g_x [-av_1^2 + (1-a)v_2^2] & 2g_x^2[u^2 - a v_1^4 + (1-a)v_2^4] \end{bmatrix}.$$  

(31)

Let the mass eigenstates of the $Z - Z'$ system be

$$Z_1 = Z \cos \theta + Z' \sin \theta, \quad Z_2 = -Z \sin \theta + Z' \cos \theta,$$

(32)

then the experimentally observed neutral gauge boson is identified in this model as $Z_1$, with mass given by

$$M_{Z_1}^2 \equiv M_Z^2 \simeq \frac{1}{2} g_Z^2 v^2 \left[ 1 - (\sin^2 \beta - a)^2 \frac{v_2^2}{u^2} \right],$$

(33)

and

$$\theta \simeq -\frac{g_Z}{2g_x} (\sin^2 \beta - a) \frac{v_2^2}{u^2}.$$ 

(34)

Note that $Z_2$ has essentially the same mass as the physical scalar boson $\sqrt{2}Re\chi$ discussed earlier.

So far, our discussion of the $Z - Z'$ sector is completely general. However, in order to make contact with experiment, we have to specify how $Z'$ interacts with the known quarks.
and leptons. In the class of $U(1)_\alpha$ models from $E_6$, all such couplings are determined. In particular, we have
\[ g_x = \sqrt{\frac{2}{3}} g_\alpha \cos \alpha, \quad a = \frac{1}{2} \left( 1 - \sqrt{\frac{3}{5}} \tan \alpha \right). \] (35)

Using the leptonic widths and forward-backward asymmetries of $Z_1$ decay, the deviations from the standard model are conveniently parametrized\[16]\:
\[ \epsilon_1 = \left[ \sin^4 \beta - \frac{1}{4} \left( 1 - \sqrt{\frac{3}{5}} \tan \alpha \right)^2 \right] \frac{v^2}{u^2} \simeq \alpha T, \] (36)
\[ \epsilon_2 = \frac{1}{4} \left( 3 - \sqrt{15} \tan \alpha \right) \left[ \sin^2 \beta - \frac{1}{2} \left( 1 - \sqrt{\frac{3}{5}} \tan \alpha \right) \right] \frac{v^2}{u^2} \simeq -\frac{\alpha U}{4 \sin^2 \theta_W}, \] (37)
\[ \epsilon_3 = \frac{1}{4} \left[ 1 - 3 \sqrt{\frac{3}{5}} \tan \alpha + \frac{1}{2 \sin^2 \theta_W} \left( 1 + \sqrt{\frac{3}{5}} \tan \alpha \right) \right] \left[ \sin^2 \beta - \frac{1}{2} \left( 1 - \sqrt{\frac{3}{5}} \tan \alpha \right) \right] \frac{v^2}{u^2} \simeq \frac{\alpha S}{4 \sin^2 \theta_W}. \] (38)

Since the experimental errors on these quantities are fractions of a percent, $u \sim \text{TeV}$ is allowed.

In the MSSM, there are four neutralinos (two gauge fermions and two Higgs fermions) which mix in a well-known $4 \times 4$ mass matrix\[17]\. Here we have six neutralinos: the gauginos of $U(1)_Y$ and the third component of $SU(2)_L$, the Higgsinos of $\tilde{\phi}_1^0$ and $\phi_2^0$, the $U(1)_X$ gaugino and the $\chi$ Higgsino. The corresponding mass matrix is then given by
\[ M_N = \begin{pmatrix}
M_1 & 0 & -g_1 v_1 / \sqrt{2} & g_1 v_2 / \sqrt{2} & 0 & 0 \\
0 & M_2 & g_2 v_1 / \sqrt{2} & -g_2 v_2 / \sqrt{2} & 0 & 0 \\
-g_1 v_1 / \sqrt{2} & g_2 v_1 / \sqrt{2} & 0 & fu & -g_x a v_1 \sqrt{2} & f v_2 \\
g_1 v_2 / \sqrt{2} & -g_2 v_2 / \sqrt{2} & fu & 0 & -g_x (1-a) v_2 \sqrt{2} & f v_1 \\
0 & 0 & -g_x a v_1 \sqrt{2} & -g_x (1-a) v_2 \sqrt{2} & M_x & g_x u \sqrt{2} \\
0 & 0 & f v_2 & f v_1 & g_x u \sqrt{2} & 0
\end{pmatrix}, \] (39)

where $M_{1,2}$ are allowed U(1) and SU(2) gauge-invariant Majorana mass terms which break the supersymmetry softly. Note that without the last two rows and columns, the above
matrix does reduce to that of the MSSM if $fu$ is identified with $-\mu$. However, the $\mu$

parameter in the MSSM is unconstrained, whereas here $fu$ is bounded and $f$ itself appears

in the Higgs potential.

Since $g_xu$ should be of order TeV, the neutralino mass matrix $\mathcal{M}_N$ reduces to either a

$4 \times 4$ or $2 \times 2$ matrix, depending on whether $f$ is much less than $g_x$ or not. In the former

case, it reduces to that of the MSSM but with the stipulation that the $\mu$ parameter must be small, i.e. of order 100 GeV. This means that the two gauginos mix significantly with the two Higgsinos and the lightest supersymmetric particle (LSP) is likely to have nonnegligible components from all four states. In the latter case, the effective $2 \times 2$ mass matrix becomes

$$\mathcal{M}'_N = \begin{pmatrix}
M_1 + g_1^2 v_1 v_2/fu & -g_1 g_2 v_1 v_2/fu
\vline
-g_1 g_2 v_1 v_2/fu & M_2 + g_2^2 v_1 v_2/fu
\end{pmatrix}. \tag{40}$$

Since $v_1v_2/u$ is small, the mass eigenstates of $\mathcal{M}'_N$ are approximately the gauginos $\tilde{B}$ and $\tilde{W}_3$, with masses $M_1$ and $M_2$ respectively. In supergravity models with uniform gaugino masses at the GUT breaking scale,

$$M_1 = \frac{5g_1^2}{3g_2^2} M_2 \simeq 0.5M_2, \tag{41}$$

hence $\tilde{B}$ would be the LSP, which makes it a good candidate for cold dark matter.

5 Supersymmetric Scalar Masses

The spontaneous breaking of the additional U(1) gauge factor at the TeV scale is not possible

without also breaking the supersymmetry. As a reasonable and predictive procedure, we

will adopt the common hypothesis that soft supersymmetry breaking operators appear at

the grand-unification (GUT) scale as the result of a hidden sector which is linked to the

observable sector only through gravity. Moreover these terms will be assumed to be universal,

i.e. of the same magnitude for all fields.
Consider now the masses of the supersymmetric scalar partners of the quarks and leptons:

$$m_B^2 = m_0^2 + m_R^2 + m_F^2 + m_D^2,$$  \hspace{1cm} (42)

where $m_0$ is a universal soft supersymmetry breaking mass at the GUT scale, $m_R^2$ is a correction generated by the renormalization-group equations running from the GUT scale down to the TeV scale, $m_F$ is the explicit mass of the fermion partner, and $m_D^2$ is a term induced by gauge symmetry breaking with rank reduction and can be expressed in terms of the gauge-boson masses. In the MSSM, $m_D^2$ is of order $M_Z^2$ and does not change $m_B$ significantly. In the $U(1)_\alpha$-extended model, $m_D^2$ is of order $M_Z'$ and will affect $m_B$ in a nontrivial way. For example, in the case of ordinary quarks and leptons,

$$\Delta m_D^2(10;1,-1) = \frac{1}{8} M_Z'^2 \left( 1 + \sqrt{\frac{3}{5}} \tan \alpha \right),$$ \hspace{1cm} (43)

$$\Delta m_D^2(5^*;1,3) = \frac{1}{8} M_Z'^2 \left( 1 - 3 \sqrt{\frac{3}{5}} \tan \alpha \right).$$ \hspace{1cm} (44)

This would have important consequences on the experimental search of supersymmetric particles. In fact, if $m_F$ is not too large, it is possible for the exotic scalars (which may be interpreted as leptoquarks depending on their Yukawa couplings) to be lighter than the usual scalar quarks and leptons. We have already discussed this issue in Ref. [18].

Assuming Eq. (42), we first consider the spontaneous breaking of $U(1)_\alpha$, i.e. $\langle \chi \rangle = u$, which requires $m_\chi^2$ to be negative. This may be achieved by considering the superpotential

$$W = f H_1 H_2 S + f' h h^c S + \lambda_t H_2 Q_3 t^c,$$ \hspace{1cm} (45)

(where we have omitted the rest of the MSSM Yukawa couplings) together with the trilinear soft supersymmetry-breaking terms

$$V_{\text{soft}} = f A_f \Phi_1 \Phi_2 \chi + f' A_f h h^c \chi + \lambda_t A_t \Phi_2 \tilde{Q}_3 \tilde{t}^c$$ \hspace{1cm} (46)

along with the soft supersymmetry-breaking scalar masses. Starting with a wide range of given values of $m_0$, the universal gaugino mass $m_{1/2}$, and the universal trilinear massive

12
parameter $A_0$ at the GUT scale, we find that $m_\chi^2$ does indeed turn negative near the TeV energy scale for many typical values of $f$ and $f'$. An example of this is given in Fig. 2. The evolution of $m_\chi^2$ is mostly driven by $f'$, but $f$ also contributes primarily through its direct effect on $A_{f'}$. From the negative value of $m_\chi^2$ at the TeV scale, we then obtain the predicted mass of $Z'$, i.e. $M_{Z'} = (-2m_\chi^2)^{1/2}$, which is also the mass of the physical scalar boson $\sqrt{2} Re\chi$. However, as we will discuss shortly, the mass of the $Z'$ so obtained must also be consistent with the desired electroweak symmetry breaking conditions.

We assume that the top quark’s pole mass is 175 GeV, and that at 1 TeV $\alpha_s = 0.1$ which corresponds to $\alpha_s(M_Z) \approx 0.12$. We will also assume that at the TeV scale and above, the particle content of the model is that of three complete $27$’s of $E_6$ and some additional field content so as to achieve gauge coupling unification. The additional field content could be near the unification scale and hence provide threshold corrections that allow the gauge couplings to unify, perhaps even at the string compactification scale. Another possibility is to add an anomaly-free pair of $SU(2)_L$ doublet fields so as to mimic gauge coupling unification in the MSSM. Such an example is discussed for the $\alpha = N$ model of Ref. [8]. This model has the same unification scale as is possible in the MSSM. In calculating the gauge-coupling beta functions, we will in fact assume the field content of that model, but the choice of additional matter fields or threshold corrections to bring about gauge coupling unification has no significant effect on our calculation. The fact that such models have three complete $27$’s has the noteworthy implication that the gauge coupling at the unification scale is approximately the strong coupling. The reason is that with three copies of $h$ and $h^c$, the beta function for $\alpha_s$ is zero in one loop above the TeV scale. Similarly, the gluino mass also does not evolve in this approximation.

Defining

$$\mathcal{D} \equiv 8\pi^2 \frac{d}{d \ln \mu}$$  \hspace{1cm} (47)
(where \( \mu \) is the scale), the relevant renormalization group equations are:

\[
\mathcal{D} \ln \lambda^2_i = - \sum_i c_i^{(t)} g_i^2 + 6 \lambda^2 t + f^2,
\]

\[
\mathcal{D} \ln f^2 = - \sum_i c_i^{(f)} g_i^2 + 3 \lambda^2 f^2 + 4 f^2 + 3 f'^2,
\]

\[
\mathcal{D} \ln f'^2 = - \sum_i c_i^{(f')} g_i^2 + 3 f^2 + 5 f'^2,
\]

for the Yukawa couplings,

\[
\mathcal{D} A_t = \sum_i c_i^{(t)} g_i^2 M_i + 6 \lambda^2 A_t + f^2 A_f,
\]

\[
\mathcal{D} A_f = \sum_i c_i^{(f)} g_i^2 M_i + 3 \lambda^2 A_t + 4 f^2 A_f + 3 f'^2 A_{f'},
\]

\[
\mathcal{D} A_{f'} = \sum_i c_i^{(f')} g_i^2 M_i + 3 f^2 A_f + 5 f'^2 A_{f'},
\]

for the trilinear scalar parameters \( A_i \), and

\[
\mathcal{D} m_S^2 = - \sum_i c_i^{(S)} g_i^2 + 2 f^2 X_f + 3 f'^2 X_{f'},
\]

\[
\mathcal{D} m_h^2 = - \sum_i c_i^{(h)} g_i^2 + f'^2 X_{f'},
\]

\[
\mathcal{D} m_{h_c}^2 = - \sum_i c_i^{(h_c)} g_i^2 + f^2 X_{f'},
\]

\[
\mathcal{D} m_{\Phi_1}^2 = - \sum_i c_i^{(\Phi_1)} g_i^2 + f^2 X_f,
\]

\[
\mathcal{D} m_{\Phi_2}^2 = - \sum_i c_i^{(\Phi_2)} g_i^2 + 3 \lambda_2^2 t + 2 f^2 X_f,
\]

\[
\mathcal{D} m_{Q_3}^2 = - \sum_i c_i^{(Q_3)} g_i^2 + \lambda_2^2 X_t,
\]

\[
\mathcal{D} m_{t_c}^2 = - \sum_i c_i^{(t_c)} g_i^2 + \lambda_2^2 X_t,
\]

where we have defined

\[
X_t \equiv m_{Q_3}^2 + m_{t_c}^2 + m_{\Phi_2}^2 + A_t^2,
\]

\[
X_f \equiv m_S^2 + m_{\Phi_1}^2 + m_{\Phi_2}^2 + A_f^2,
\]

\[
X_{f'} \equiv m_S^2 + m_h^2 + m_{h_c}^2 + A_{f'}^2,
\]
and the coefficients $c_i^{\text{(field)}}$ have the obvious values. Further, the gaugino mass $M_i$ scales the same as $\alpha_i$. These equations are modified in an obvious manner if $\tan \beta$ is large enough that $\lambda_b$ and $\lambda_t$ cannot be ignored or if there are more than one sizeable coupling serving the purpose of $f'$, which is certainly possible since we have three copies of $h$ and $h^c$ in these models.

A very important outcome of Eq. (42) is that the $U(1)_\alpha$ and electroweak symmetry breakings are related. To see this, go back to the two-doublet Higgs potential $V$ of Eq. (10). Using Eqs. (6) to (9) and Eq. (35), we can express the parameters $m_{12}^2$, $m_1^2$, and $m_2^2$ in terms of the mass of the pseudoscalar boson $m_A$, and $\tan \beta$.

\begin{align*}
m_{12}^2 &= -m_A^2 \sin \beta \cos \beta, \\
m_1^2 &= m_A^2 \sin^2 \beta - \frac{1}{2} M_Z^2 \cos 2 \beta \\
&\quad - \frac{2f^2}{g_Z^2} M_Z^2 \left[ 2 \sin^2 \beta + \left( 1 - \sqrt{\frac{3}{5}} \tan \alpha \right) \cos^2 \beta - \frac{3f^2}{2 \cos^2 \alpha g_a^2} \right], \\
m_2^2 &= m_A^2 \cos^2 \beta + \frac{1}{2} M_Z^2 \cos 2 \beta \\
&\quad - \frac{2f^2}{g_Z^2} M_Z^2 \left[ 2 \cos^2 \beta + \left( 1 + \sqrt{\frac{3}{5}} \tan \alpha \right) \sin^2 \beta - \frac{3f^2}{2 \cos^2 \alpha g_a^2} \right].
\end{align*}

On the other hand, using Eq. (42), we have

\begin{align*}
m_{12}^2 &= fAfu, \\
m_1^2 &= m_0^2 + m_{R1}^2 + f^2 u^2 - \frac{1}{4} \left( 1 - \sqrt{\frac{3}{5}} \tan \alpha \right) M_Z^2, \\
m_2^2 &= m_0^2 + m_{R2}^2 + f^2 u^2 - \frac{1}{4} \left( 1 + \sqrt{\frac{3}{5}} \tan \alpha \right) M_Z^2,
\end{align*}

where $m_{R1}^2$ and $m_{R2}^2$ differ in that $\lambda_t$ (the Yukawa coupling of $\Phi_2$ to the $t$ quark) contributes to the latter but not to the former. Both depend on $m_0$, $m_{1/2}$, $A_0$, the various gauge couplings $g_i$, as well as $f$ and $f'$. Matching Eqs. (64) to (66) with Eqs. (67) to (69) allows us to determine $u$ and $\tan \beta$ for a given set of parameters at the grand-unification scale.
We will now briefly discuss our method for finding \( u \) and \( \tan \beta \) for a given set of universal soft supersymmetry-breaking parameters \( m_3, m_0, A_0 \) at the GUT scale and the Yukawa coupling \( f \), when such a solution exists. First, we guess a value for \( \tan \beta \) so as to choose a value for \( \lambda_t \). We then form a table \([M_{Z'}, m^2_{R1}, m^2_{R2}, A_f](f')\) for many very closely spaced values of \( f' \) extending up to where \( f'(M_G) \) reaches its perturbative limit. By “closely spaced values of \( f' \),” we mean that between two consecutive entries in the table, none of the four parameters differs by more than one percent. Second, we guess a value for \( M_{Z'} \) which lies within the range in the table, so as to choose \( m^2_{R1}, m^2_{R2}, A_f \) from the entry of the table which has \( M_{Z'} \) closest to this value. Third, we equate the right-hand sides of Eq. (65) + Eq. (66) and Eq. (68) + Eq. (69) to solve for \( m^2_A \) as a linear function of \( u^2 \) and \( \cos^2 \beta \). Fourth, using the previous result for \( m^2_A \) we equate the right-hand sides of Eq. (65) − Eq. (66) and Eq. (68) − Eq. (69) to solve for \( u^2 \) as a function of \( \cos^2 \beta \) of the form of a linear function divided by another linear function. Fifth, using the expressions from the previous two steps we equate the right-hand sides of Eq. (64) with that of Eq. (67) and solve numerically for \( \cos^2 \beta \), and hence \( \tan \beta \), by first searching for a root close to the value corresponding to our original guess for \( \tan \beta \). In doing this fifth step, one needs to choose \( fu > 0 \) or \( fu < 0 \) analagous to \( \mu > 0 \) or \( \mu < 0 \) in the MSSM, and then check that the solution is consistent with \( m^2_A = -f A_f u / \sin \beta \cos \beta > 0 \). In fact, taking all Yukawa couplings and \( \tan \beta \) to be positive as well as our convention for the trilinear coupling parameters \( A_i \), solutions exist only for \( u < 0 \). Next, if a solution to these steps has been found, we start the entire cycle over using the values for \( \tan \beta \) and \( M_{Z'} \) just calculated as the new “guessed” values. This iteration is continued until the predicted \( \tan \beta \) and \( M_{Z'} \) become fixed to a reasonable accuracy (we demand about five-percent accuracy). This process can be speeded up by adding a sixth step to the cycle which repeats the third through fifth steps until the prediction for \( \tan \beta \) and \( M_{Z'} \) become fixed for the table found in the second step of the cycle.
Before we discuss our results, we remind the reader that for the case that $A_f$ could be small $f$ has a maximum possible value that comes from requiring that the Higgs potential be bounded from below and which depends on the additional U(1). We plot this maximum value $f_{\text{max}}$ as a function of $\alpha$ (see Eq. (20)) in Fig. 3. In particular, the $\eta$–model requires $f$ to be less than about 0.35, whereas for $\alpha = 0$, $f$ could be as great as 0.46. Note that as $|\alpha|$ approaches $\pi/2$, $f_{\text{max}}$ approaches 0. From Fig. 2(a), one can see that if $f$ is small enough so that $\alpha = \eta$ is allowed, then $f(M_G)$ will always be perturbatively small for a perturbatively valued $f'$. In our examples, we will only be interested in values of $f < 0.35$.

In Fig. 4, we show the predicted values of $\tan \beta$ and $M_{Z'}$ as a function of $\alpha$ for $f = 0.345$ and $m_{\tilde{g}} = 200$ GeV, $A_0 = 650$ GeV and $m_0 = 650$ GeV. In accordance with Fig. 3, we are only interested in showing $|\alpha|$ less than about 0.7. We have also plotted the magnitude $|u|$ of the VEV of the singlet Higgs boson $\chi$ and the mass $f'|u|$ of the exotic fermion $h(h^c)$. In Fig. 5, we show the similar situation for $f = 0.345$ and $m_{\tilde{g}} = 300$ GeV, $A_0 = 950$ GeV and $m_0 = 950$ GeV. These two figures are quite similar except that the mass scale in Fig. 5(b) has been pushed up relative to that shown in Fig. 4(b). These choices of soft supersymmetry-breaking parameters are fairly typical in that generally we need $m_0$ to be at least twice as great as $m_{\tilde{g}}$ to find a solution. Further, if we want to have a solution for all $\alpha$ less than some value, $A_0$ must be positive and of order $m_0$.

In Figs. 6-9, we illustrate the effects of varying the parameters $f, m_{\tilde{g}}, A_0, m_0$ for a fixed value of $\alpha = \eta$. We look at the solutions for $\tan \beta$ and $M_{Z'}$ (as well as $|u|$ and $f'|u|$) when the four input parameters are varied one at a time around the point $f = 0.345$ and $m_{\tilde{g}} = 250$ GeV, $A_0 = 650$ GeV and $m_0 = 650$ GeV. Note from Fig. 6 that with decreasing $f$, $\tan \beta$ and $M_{Z'}$ both increase. We do not extend $f$ above 0.345 so as to avoid the upper bound coming from Fig. 3. We find also that we cannot decrease $f$ much below 0.32 for this example and still have a solution for the electroweak breaking. To use smaller values of $f$, one would have
to increase the scale of the soft supersymmetry-breaking parameters. In Fig. 7, we look at the effect of varying $A_0$. The range of $A_0$ examined is restricted because any extension in either direction would require values of $M_{Z'}$ larger than can be reached via the $f'hh'S$ term with $f'$ within the perturbative regime. In Fig. 8, we vary $m_0$. Note that with increasing $m_0$, the predicted $\tan \beta$ increases significantly and $M_{Z'}$ decreases. In this example, increasing $m_0$ beyond 1200 GeV would predict an $M_{Z'}$ less than 500 GeV and a $\tan \beta$ greater than 10. The lower limit of 500 GeV for $m_0$ used here is due to the same reason as just given for the range of $A_0$ plotted in the previous figure. In Fig. 9, we show the effect of varying the gluino mass which is also here the GUT scale universal gaugino mass. With increasing gluino mass, $\tan \beta$ decreases while $M_{Z'}$ increases. The upper limit of 350 GeV used here for the gluino mass again corresponds to about the size of that parameter for this example where increasing it anymore would require values of $|u|$ larger than can be reached perturbatively through the renormalization-group equations. We find the general trends of Fig. 6-9 to be typical of other choices of parameter values where consistent solutions exist.

If $m_0$ is demanded to be less than about 1 TeV, then in general $\tan \beta < 10$, where the $b$ and $\tau$ Yukawa couplings are small enough not to contribute significantly to the renormalization-group equations. It is interesting to note that in contrast to the MSSM, where $m_1^2 - m_2^2 = -m_{R_2}^2(\lambda_t) = -(m_\lambda^2 + m_Z^2) \cos 2\beta$, solutions with $\tan \beta < 1$ in principle are possible here due to the TeV scale D-terms. However, to have such a solution in practice with $m_t^{(\text{pole})} \approx 175$ GeV means having $\lambda_i(t_i)$ greater than its fixed-point value of about 1.22 with $\alpha_G = \alpha_s(1 \text{ TeV}) \approx 0.1$ where the gauge couplings run according to the additional exotic field content as we have chosen.

If $f A_f / g_x^2 u$, where $g_x^2 = (2/3) g_1^2 \cos^2 \alpha$ is not small, then Eqs. (64) to (66) have additional contributions, but they are always suppressed by $v^2/u^2$ relative to $m_{12}^2 = f A_f u$, hence our numerical results on $\tan \beta$ and $M_{Z'}$, etc. do not change appreciably. The corrections are
only important if the masses and splittings of the two Higgs doublets are considered.

6 Conclusions

We have shown in this paper that there are many interesting and important phenomenological consequences if we assume the existence of a supersymmetric U(1) gauge factor at the TeV energy scale. We assume that there is a Higgs superfield $S$ which is a singlet under the standard gauge group but which transforms nontrivially under this extra U(1) so that it may break the latter spontaneously without breaking the former. We assume also that $H_1H_2S$ is an allowed term in the superpotential. We then analyze the most general form of the Higgs potential and derive an upper limit on the lighter of the two neutral scalar Higgs bosons of the two-doublet Higgs sector as shown in Fig. 1. This generalizes the well-known case of the Minimal Supersymmetric Standard Model (MSSM).

We then specialize to the case where this extra U(1) is derivable from a $E_6$ model with the particle content given by its fundamental $27$ representation. We discuss the effect on $Z - Z'$ mixing and the oblique parameters $\epsilon_{1,2,3}$, as well as the extended neutralino mass matrix. We then work out in detail the consequences for supersymmetric scalar masses. We note that the mere existence of a spontaneously broken U(1) gauge factor at the TeV scale implies new important corrections to these masses through the so-called D-terms which are now dominated by $M_{Z'}^2$ instead of just $M_Z^2$ in the MSSM. This changes the entire supersymmetric scalar particle spectrum and should not be overlooked in future particle searches.

Assuming universal soft supersymmetry-breaking terms at the grand-unification (GUT) scale, we match the electroweak breaking parameters with the corresponding ones from the U(1) breaking. Specifically, the values of $m_1^2$, $m_2^2$, and $m_{12}^2$ in the well-known two-doublet Higgs potential are constrained as shown by Eqs. (64) to (69). We then obtain consistent
numerical solutions to these constraints and demonstrate how the U(1) breaking scale and the parameter $\tan \beta \equiv v_2/v_1$ are related through the $H_1 H_2 S$ coupling. Our results are presented in Figs. 2 to 9.

During the final stage of completing this manuscript, we became aware of Ref. [19], which also discusses electroweak symmetry breaking with an additional supersymmetric U(1) gauge factor, but the emphasis there is on the case $f' = 0$. The case $f' \neq 0$ is also discussed there, but the conclusion is that whereas the breaking of the additional U(1) radiatively via the term $f' hh c S$, already noted in Ref. [2], can be achieved with universal soft supersymmetry-breaking terms at the GUT scale, it does not work in the large trilinear coupling scenario. Our approach is essentially orthogonal. We concentrate on solutions where the U(1) scale is much larger than the electroweak scale. With the two scales being intimately related through the matching of Eqs. (64) to (66) with Eqs. (67) to (69), it is in fact highly nontrivial to find solutions which are consistent with this matching even with an arbitrary $f'$. We note also that our examples are models with complete $E_6$ particle content and in our approximation, the Yukawa coupling $f$ is bounded as shown in Fig. 3. In the more general case, the bound on $f$ increases as the trilinear coupling increases.
