In the context of a canonical quantization of general relativity, one can deform the loop gravity phase space on a graph by replacing the $T^\ast SU(2)$ phase space attached to each edge by $SL(2,\mathbb{C})$ seen as a phase space. This deformation is supposed to encode the presence of a non-zero cosmological constant. Here we show how to parametrize this phase space in terms of spinor variables, thus obtaining deformed spinor networks for loop gravity, with a deformed action of the gauge group $SU(2)$ at the vertices. These are to be formally interpreted as the generalization of loop gravity twisted geometries to a hyperbolic curvature.

Introduction

Loop quantum gravity is an approach to quantum gravity, based on a canonical quantization of general relativity formulated as a gauge field theory (typically $SU(2)$ or $SL(2,\mathbb{C})$ depending on the precise formulation). It defines quantum states of geometry and encodes the theory’s dynamics in quantum Hamiltonian constraints generating space-time diffeomorphisms. In this context, the cosmological constant $\Lambda$ is a mere coupling constant (for the 3-volume term) entering the Hamiltonian.

There are nevertheless many claims that we could encode it in a quantum deformation of the gauge group. Such claims are backed up by rigorous analysis in 2+1-dimensional quantum gravity, for which there are clear relations between the cosmological constant and quantum group deformation (see e.g. [1] for a summary). These studies are mostly based on the Chern-Simons reformulation of 2+1d gravity, seen from the perspectives of path integral quantization [2,3] and Hamiltonian or combinatorial quantization [4–7], but also on the Turaev-Viro state-sum model [8] defining a topological spinfoam path integral for 3d quantum gravity based on $U_q(su(2))$ and believed to account for a non-vanishing cosmological constant (based on the asymptotics of the quantum-deformed 6j-symbol) [9,10]. We refer also to [11] for the link between the spinfoam quantization and the combinatorial quantization and the more recent works [12–15] for attempts to relate the spinfoam framework and the canonical loop gravity quantization.

The previous work [16] showed how to deform at the classical level the loop gravity phase space (on a fixed graph) and analyzed in details its deformed symmetries. It was then shown in [17] that its quantization yields to spin networks states based on the quantum gauge group $U_q(su(2))$. The results in [16] were based on the deformation of the $T^\ast SU(2)$ phase space identified as the (double cover of the) ISO(3) Poincaré group to the $SL(2,\mathbb{C})$ phase space with Poisson brackets defined in terms of the classical $r$-matrix of $sl_2$. The deformed loop gravity phase space on a given graph was then defined as many copies of this $SL(2,\mathbb{C})$ phase space together with a deformed action of the $SU(2)$ gauge group on the data at the graph vertices. We further discussed the geometrical interpretation of this deformed loop gravity phase space on (3-valent) graphs within the context of 3d gravity. More precisely, we proved that a graph dressed with $SL(2,\mathbb{C})$ group elements along the edges, provided with appropriate gauge invariant $SU(2)$ flatness constraints, could be interpreted as defining a discrete hyperbolic surface, built from hyperbolic triangles (dual to the graph vertices) glued together consistently within the 3d one-sheet-hyperboloid (defined as set of unit time-like vectors in 4d Minkowski space-time).

Here we introduce and investigate a reformulation of this hyperbolically-deformed phase space in terms of spinor variables. Indeed in standard loop quantum gravity (with $\Lambda = 0$), there has been a growing interest in the reformulation of the loop gravity phase space in terms of twisted geometries and spinor networks [18–23]. These tools brought a clarification of the geometrical meaning of the holonomy-flux observables on a graph at the classical level and of spin network states at the quantum level. A big advantage of this formalism is a straightforward quantization of the spinor variables parametrizing the phase space and a straightforward construction of coherent states of geometry [21,24,25].
They also led to new insights on spinfoam amplitudes (for the dynamics of spin networks in loop quantum gravity) and on the associated 3nj-symbols of spin recoupling, providing a new light on the recursion relations and generating functions for the amplitudes and allowing for some exact analytical evaluations [26–29]. This spinorial formalism also turned out to be relevant from a purely mathematical point of view, see e.g. [30].

We set on introducing a similar parametrization of the SL(2, C) phase space in terms of spinor variables. Given an oriented graph, we consider two spinors (complex 2-vectors) on each edge, one at each end of the edge. We will reconstruct the whole SL(2, C) phase space for these spinors, both the vector variables (the generalization of the fluxes), identified as triangular matrices, and the SU(2) holonomy along the edge. We will identify canonical spinor variables, as Darboux coordinates for the phase space, that do not transform simply under SU(2) transformations, and we will also define non-canonical spinors, that transform properly as spin-1/2 vectors for the fundamental representation of SU(2), from which we can directly reconstruct the vector variables as quadratic polynomials in their components.

The paper goes as follows. In a first section, we review the standard construction of the \( T^*\text{SU}(2) \sim \text{ISO}(3) \) phase space from spinor variables. We review in the second section the definition of the SL(2, C) phase space, parametrized in terms of triangular matrices and SU(2) group elements. The third and fourth sections introduce the new spinor variables and shows how to define the triangular matrices from them. The fifth section describes how to reconstruct the whole SL(2, C) phase space from the spinors. The sixth section summarizes the new spinorial parametrization of the hyperbolically-deformed loop gravity phase space and the deformed action of SU(2) transformations on all the variables. We conclude with a discussion on the possibilities opened by this formalism.

**I. STANDARD SPINOR PHASE SPACE AND HOLONOMY RECONSTRUCTION**

Let us consider a spinor \( |\zeta\rangle \in \mathbb{C}^2 \) and its conjugate \( \langle \bar{\zeta}| \in \mathbb{C}^2 \),

\[
|\zeta\rangle = \begin{pmatrix} \zeta_0 \\ \zeta_1 \end{pmatrix}, \quad \langle \bar{\zeta}| = (\bar{\zeta}_0, \bar{\zeta}_1),
\]

provided with the canonical Poisson brackets:

\[
\{\zeta_0, \bar{\zeta}_0\} = \{\zeta_1, \bar{\zeta}_1\} = -i. \tag{2}
\]

We also introduce the dual spinor:

\[
|\bar{\zeta}\rangle = \begin{pmatrix} -\bar{\zeta}_1 \\ \bar{\zeta}_0 \end{pmatrix} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} |\zeta\rangle, \quad \langle \bar{\zeta}| = \begin{pmatrix} -\zeta_1 \\ \zeta_0 \end{pmatrix}. \tag{3}
\]

We will also write \( N_A = \zeta_A \bar{\zeta}_A \) for the modulus of the spinor components for \( A = 0, 1 \) and \( N = N_0 + N_1 \) for their sum. It is easy to check that these generate dilatations on the complex variables:

\[
\{N_A, \zeta_B\} = i\delta_{AB}\zeta_A, \quad \{N_A, \bar{\zeta}_B\} = -i\delta_{AB}\bar{\zeta}_B. \]

Considering the rank-1 Hermitian matrix \( X \equiv |\zeta\rangle \langle \zeta| \), one defines its projection onto the identity and the Pauli matrices \( \sigma_i \) for \( i = 1..3 \):

\[
X_0 = \frac{1}{2} \text{Tr}|\zeta\rangle \langle \zeta| = \frac{1}{2} (|\zeta| |\zeta|) = \frac{N_0 + N_1}{2}, \quad \bar{X} = \frac{1}{2} \text{Tr}\bar{\zeta} \langle \zeta| = \frac{1}{2} \langle \bar{\zeta}| \bar{\zeta} \rangle \in \mathbb{R}^3, \quad X = \left( X_0 \mathbb{1} + \bar{X} \cdot \bar{\sigma} \right). \tag{4}
\]

These satisfy the obvious equality \( X_0 = |\bar{X}| \) and their Poisson brackets form a \( su(2) \) algebra:

\[
\{X_i, X_j\} = \epsilon_{ijk}X_k, \quad \{X_0, \bar{X}\} = 0. \tag{5}
\]

We can also decompose this in self-dual and anti-self-dual dual components:

\[
X = X_0 \mathbb{1} + X_3 \sigma_3 + X_+ \sigma_+ + X_- \sigma_- = \begin{pmatrix} X_0 + X_3 \\ X_+ \\ X_+ (X_0 - X_3) \end{pmatrix}, \quad X_+ = \zeta_0 \bar{\zeta}_1, \quad X_- = \zeta_0 \bar{\zeta}_1,
\]

\[
\{X_3, X_\pm\} = \mp iX_\pm \quad \{X_+, X_-\} = -2iX_3. \tag{6}
\]
Note that $[\zeta|\bar{\sigma}|\zeta] = -\langle \zeta|\bar{\sigma}|\zeta \rangle$ hence the dual spinor $|\zeta \rangle$ defines the opposite vector $-\vec{X}$. The vector $\vec{X}$ actually generates SU(2) transformations on the spinor:

$$\{\vec{X}, |\zeta \rangle \} = \left( \begin{array}{c} \frac{i}{2} \bar{\sigma} |\zeta \rangle , \\ e^{(\vec{X}, \bullet)} |\zeta \rangle = e^{\vec{X} \cdot \bar{\sigma}} |\zeta \rangle , \\ e^{\vec{X} \cdot \bar{\sigma}} \in \text{SU}(2) \end{array} \right).$$

(7)

These finite SU(2) transformations act on the spinor $\zeta$ as 2x2 matrices as in the fundamental representation while they simply induce 3d rotations on the vector $\vec{X}$:

$$\left( \begin{array}{c} \langle \zeta \rangle \\ |\zeta \rangle \end{array} \right) \mapsto \begin{pmatrix} g & 0 \\ 0 & g \end{pmatrix} \left( \begin{array}{c} \langle \zeta \rangle \\ |\zeta \rangle \end{array} \right) \mapsto X \mapsto gXg^{-1} \mapsto \left( \begin{array}{c} X_0 \\ \vec{X} \end{array} \right) \mapsto g^{-1} \times \vec{X}$$

(8)

where the spinor $\zeta$ and its dual both transform properly under SU(2) transformations. We can also give the details of the infinitesimal transformations of the spinor components:

$$\begin{align*}
\{X_3, \zeta_0\} &= \frac{i}{2} \zeta_0 \\
\{X_+, \zeta_0\} &= i \zeta_1 \\
\{X_-, \zeta_0\} &= 0 \\
\{X_+, \zeta_1\} &= 0 \\
\{X_-, \zeta_1\} &= i \zeta_0
\end{align*}$$

We now consider one oriented edge of a twisted geometry. We have two vectors at each end of the edge, $\vec{X}$ and $\vec{\tilde{X}}$, and a SU(2) group element $g$. We assume the standard $T^*\text{SU}(2)$ Poisson brackets:

$$\begin{align*}
\{X_i, g\} &= -\frac{i}{2} g \sigma_i, \\
\{X_i, X_j\} &= \epsilon_{ijk} X_k, \\
\{X_i, X_j\} &= \epsilon_{ijk} X_k.
\end{align*}$$

(9)

(10)

Now we further impose the condition that the holonomy $g$ sends one vector onto the other, which can be equivalent written in terms of the corresponding 2x2 Hermitian matrices $X$ and $\vec{X}$ (see Fig. 1):

$$g^{-1} \times \vec{X} = -\vec{X}, \quad gXg^{-1} = \vec{X}^s, \quad \text{with} \quad X = \frac{1}{2}(|\vec{X}| I + \vec{X} \cdot \bar{\sigma}), \quad \vec{X}^s = \frac{1}{2}(|\vec{X}| I - \vec{X} \cdot \bar{\sigma}).$$

(11)

The sign flip is important for the consistency of this condition with the Poisson brackets. Indeed it compensates the sign difference in the brackets of $X$ and $\vec{X}$ with the holonomy $g$ in (9) so that the brackets of this parallel transport condition with $g$, $X$ and $\vec{X}$ vanish. This condition $gXg^{-1} = \vec{X}^s$ can be re-written in terms of 3d Poincaré transformations or equivalently as ISO(3) $\sim \text{SU}(2) \times \mathbb{R}^3$ group elements represented as pairs consisting of a rotation and a translation :

$$(g, \vec{X}) = (I, \vec{X})(g, 0) = (g, 0)(I, -\vec{X}) = (g, -g \times \vec{X}).$$

Noticing that the parallel transport condition $gX = \vec{X}^s g$ does not entirely fix the holonomy $g$ in terms of the two vectors $X$ and $\vec{X}$ but leaves the possibility of an arbitrary 3d rotation around the $\vec{X}$ axis for instance. It is possible to replace this condition by a slightly stronger one using spinor variables. This parametrization of twisted geometries in terms of spinors allows to reconstruct both vectors variables $X$, $\vec{X}$ and SU(2) holonomies $g$ as composite observables on the spinor phase space. These structures are called the spinor networks.

Starting with two spinors $\zeta$ and $\tilde{\zeta}$ as above, we define the vectors $X$ and $\vec{X}$ as previously:

$$X = |\zeta \rangle \langle \zeta|, \quad \vec{X} = |\tilde{\zeta} \rangle \langle \tilde{\zeta}|.$$

(12)

We assume the norm matching condition, $\langle \zeta|\zeta \rangle - \langle \tilde{\zeta}|\tilde{\zeta} \rangle = 0$, which implies that $X$ and $\vec{\tilde{X}}$ have equal norms. We then define the holonomy $g$ as the unique SU(2) group element mapping the $\mathbb{C}^2$ orthonormal basis $|\zeta \rangle, |\tilde{\zeta} \rangle$ to $|\tilde{\zeta} \rangle, -|\zeta \rangle$:

$$g = \frac{|\tilde{\zeta} \rangle \langle \zeta| - |\zeta \rangle \langle \tilde{\zeta}|}{\sqrt{\langle \zeta|\zeta \rangle \langle \tilde{\zeta}|\tilde{\zeta} \rangle}} \in \text{SU}(2), \quad g |\zeta \rangle = |\tilde{\zeta} \rangle, \quad g |\tilde{\zeta} \rangle = -|\zeta \rangle.$$ 

(13)

This properly implements the required parallel transport:

$$gXg^{-1} = g|\zeta \rangle \langle \zeta|g^{-1} = |\tilde{\zeta} \rangle \langle \tilde{\zeta}| = \vec{X}^s.$$ 

(14)
Finally, it is straightforward to check that the components of this SU(2) group element weakly commute with each other assuming the norm-matching-condition:

\[ \{ g_1, g_2 \} \simeq 0 \],

which provides us with the correct \( T^* \text{SU}(2) \) Poisson structure.

Note that it is possible to avoid the sign flip of \( \tilde{X} \) in this formalism. Imposing \( gX = \tilde{X}g \) would require switching the sign of the brackets \( \{ \tilde{X}, g \} \) and \( \{ X, \tilde{X} \} \). Modifying the latter would create an asymmetry between the \( X \) and \( \tilde{X} \) sectors.

II. SL(2, \mathbb{C}) PHASE SPACE

The SL(2, \mathbb{C}) phase space is defined from the SL(2, \mathbb{C}) group element \( D \) provided with the following Poisson bracket:

\[ \{ D_1, D_2 \} = -r D_1 D_2 - D_1 D_2 r^\dagger, \]

with the standard convention \( D_1 = D \otimes \mathbb{I} \) and \( D_2 = \mathbb{I} \otimes D \) and the classical \( r \)-matrix:

\[ r = \frac{\kappa}{4} \sum_i \tau_i \otimes \sigma_i = \frac{i \kappa}{4} \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 4 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \]

in terms of the Pauli matrices \( \sigma_i \) and \( \tau_i \). We are using here the usual notation for the tensor product of two \( 2 \times 2 \) matrices as a \( 4 \times 4 \) matrix:

\[ A_1 B_2 = A \otimes B = \begin{pmatrix} A_{11} B_2 & A_{12} B_2 \\ A_{21} B_2 & A_{22} B_2 \end{pmatrix}. \]

The key to our analysis of the phase space structure is the (left) Iwasawa decomposition SL(2, \mathbb{C}) = \text{SB}(2, \mathbb{C}) \bowtie \text{SU}(2):

\[ D = \ell u, \quad \ell \in \text{SB}(2, \mathbb{C}), \quad u \in \text{SU}(2). \]

The SL(2, \mathbb{C}) bracket \[16\] reads in this parametrization:

\[ \{ \ell_1, \ell_2 \} = -[r, \ell_1 \ell_2], \quad \{ u_1, u_2 \} = [r^\dagger, u_1 u_2], \quad \{ \ell_1, u_2 \} = -\ell_1 r u_2, \quad \{ u_1, \ell_2 \} = -\ell_2 r^\dagger u_1. \]

To get the full symplectic structure, one also computes the brackets with the complex conjugate variables \( \ell^\dagger \). For more details, the reader can refer to \[16\]. Defining \( l = \ell^\dagger - 1 \), we get:

\[ \{ l_1, l_2 \} = -[r^\dagger, l_1 l_2]. \]

This formula contains all the brackets between the components of \( \ell \) and their complex conjugate. More precisely, we explicitly parametrize the triangular matrix as:

\[ \ell = \begin{pmatrix} \lambda & 0 \\ z & \lambda^{-1} \end{pmatrix} \in \text{SB}(2, \mathbb{C}), \quad \lambda \in \mathbb{R}_+, \quad z \in \mathbb{C}, \]

and compute the Poisson algebra:

\[ \{ \lambda, z \} = \frac{i \kappa}{2} \lambda z, \quad \{ \lambda, \bar{z} \} = -\frac{i \kappa}{2} \lambda \bar{z}, \quad \{ z, \bar{z} \} = i \kappa (\lambda^2 - \lambda^{-2}) . \]

Let us underline that these brackets are invariant under the exchange \( \ell \leftrightarrow \bar{\ell}^{-1} \), or explicitly \( (\lambda, z) \leftrightarrow (\lambda^{-1}, \bar{z}) \).

Here we have used the left Iwasawa decomposition. We will also need the right Iwasawa decomposition, which corresponds to the left Iwasawa decomposition for the inverse of the SL(2, \mathbb{C}) group element \( D \):

\[ D = \tilde{\ell}^{-1} \bar{\ell}, \quad D^{-1} = \tilde{\ell} \bar{\ell}. \]
FIG. 1: We fatten the edges of a graph into a ribbon. The ribbon can be read clockwise as a plaquette encoding the constraint $(\tilde{\ell}\tilde{u})(\ell u) = D^{-1}D = I$, which encodes the equivalence of the two Iwasawa decompositions.

We use a slightly different convention from the one previously used in [16], to account for the sign flip. The Poisson brackets for the components of the inverse matrix are easy to compute:

$$\{D_1^{-1}, D_2^{-1}\} = -r^\dagger D_1^{-1}D_2^{-1}D_1^{-1}D_2^{-1}r,$$

which amounts in the end to switching the classical $r$-matrix with its Hermitian conjugate. This leads to the following brackets between the triangular matrix and the SU(2) holonomy:

$$\{\tilde{\ell}_1, \tilde{\ell}_2\} = -[r, \tilde{\ell}_1\tilde{\ell}_2], \quad \{\tilde{u}_1, \tilde{u}_2\} = [r, \tilde{u}_1\tilde{u}_2], \quad \{\tilde{\ell}_1, \tilde{u}_2\} = -\tilde{\ell}_1r^\dagger\tilde{u}_2, \quad \{\tilde{u}_1, \tilde{\ell}_2\} = -\tilde{\ell}_2r\tilde{u}_1. \quad (25)$$

We complete this algebra with the bracket with the complex conjugate of the triangular matrix, $\tilde{\ell} = \tilde{\ell}^\dagger$:

$$\{\tilde{\ell}_1, \tilde{\ell}_2\} = -[r, \tilde{\ell}_1\tilde{\ell}_2]. \quad (26)$$

Parametrizing the triangular matrix $\tilde{\ell}$ as before:

$$\tilde{\ell} = \begin{pmatrix} \hat{\lambda} & 0 \\ \hat{z} & \hat{\lambda}^{-1} \end{pmatrix},$$

we get exactly the same brackets for the tilded sector as for the original sector:

$$\{\hat{\lambda}, \hat{z}\} = \frac{i\kappa}{2}\hat{\lambda}\hat{z}, \quad \{\hat{\lambda}, \hat{\lambda}\} = -\frac{i\kappa}{2}\hat{\lambda}\hat{\lambda}, \quad \{\hat{z}, \hat{z}\} = i\kappa\left(\hat{\lambda}^2 - \hat{\lambda}^{-2}\right). \quad (27)$$

We can also calculate the Poisson brackets between the two different decompositions.

$$\{\ell_1, \ell_2\} = \{u_1, \tilde{u}_2\} = 0, \quad \{\tilde{u}_1, \ell_2\} = \tilde{u}_1r^\dagger\ell_2, \quad \{\tilde{\ell}_1, u_2\} = u_2r\tilde{\ell}_1. \quad (28)$$

Our goal will be first to reproduce the Poisson brackets (27) from some spinor variables and then to reconstruct the whole SL(2, $\mathbb{C}$) phase space, with in particular the SU(2) group elements $u$ and $\tilde{u}$, from those spinors.

### III. NEW SPINOR VARIABLES AND DEFORMED ACTION OF ROTATIONS

We now define $\kappa$-deformed spinors $|\zeta^\kappa\rangle$, $\langle\zeta^\kappa|$ with components

$$\zeta_A^\kappa = \zeta_A\sqrt{\frac{2\sinh(\frac{\kappa N_A}{2})}{N_A}}, \quad \bar{\zeta}_A^\kappa = \bar{\zeta}_A\sqrt{\frac{2\sinh(\frac{\kappa N_A}{2})}{N_A}}. \quad (29)$$

We do not change the definition of the $N$’s, keeping $N_A^\kappa = N_A = \zeta_A\bar{\zeta}_A$ for both $A = 0, 1$, but the norm $\zeta_A^\kappa\bar{\zeta}_A^\kappa$ of the deformed spinor has a $N_A$-dependent factor:

$$\zeta_A^\kappa\bar{\zeta}_A^\kappa = 2\sinh\left(\frac{\kappa N_A}{2}\right) = e^{\frac{\kappa N_A}{2}} - e^{-\frac{\kappa N_A}{2}}, \quad (30)$$
These \( \kappa \)-deformed spinors satisfy simple Poisson brackets among themselves

\[
\{ \zeta^\kappa_A, \bar{\zeta}^\kappa_B \} = -i \delta_{AB} \kappa \cosh\left( \frac{\kappa N_A}{2} \right), \quad \{ N_A, \zeta^\kappa_B \} = i \delta_{AB} \zeta^\kappa_A, \quad \{ N_A, \bar{\zeta}^\kappa_B \} = -i \delta_{AB} \bar{\zeta}^\kappa_A. \tag{31}
\]

We check the limit \( \kappa \to 0^+ \) when we should recover the undeformed quantities and we get as expected at leading order in the deformation parameter:

\[
\zeta^\kappa_A \sim \sqrt{\kappa} \zeta_A, \quad \bar{\zeta}^\kappa_A \bar{\zeta}^\kappa_A \sim \kappa N_A, \quad \{ \zeta^\kappa_A, \bar{\zeta}^\kappa_B \} \sim -i \delta_{AB} \kappa. \tag{32}
\]

Then, from these \( \kappa \)-deformed spinors, we build the lower triangular matrix \( \ell \in \text{SB}(2, \mathbb{C}) \) with

\[
\ell = \begin{pmatrix} \lambda & 0 \\ z & \lambda^{-1} \end{pmatrix} \in \text{SB}(2, \mathbb{C}), \quad \lambda = \exp\left( -\frac{\kappa}{4} (N_0 - N_1) \right), \quad z = \bar{\zeta}^\kappa \zeta^\kappa. \tag{33}
\]

It is easy to check that they satisfy the expected Poisson brackets,

\[
\{ \lambda, z \} = \frac{i \kappa}{2} \lambda z, \quad \{ \lambda, \bar{z} \} = -\frac{i \kappa}{2} \lambda \bar{z}, \quad \{ z, \bar{z} \} = i \kappa (\lambda^2 - \lambda^{-2}). \tag{34}
\]

Let us point out that the components of the triangular matrix \( \ell \) all commute with \( N = N_0 + N_1 \):

\[
\{ N, \ell \} = \{ N, \lambda \} = \{ N, z \} = 0, \tag{35}
\]

which simply expresses invariance of \( \lambda \) and \( z \) under \( \text{U}(1) \) phase transformation of the spinors \( |\zeta^\kappa \rangle \to e^{i \theta} |\zeta^\kappa \rangle \). An important remark to underline is that the parameter \( z \) is not holomorphic in the spinors \( \zeta^\kappa \) and that the notion of holomorphicity depends here on the considered variables (for instance, \( \zeta \) or \( \zeta^\kappa \) or \( \ell \)).

Up to now, we have merely introduced a re-parametrization of the same phase space as in the undeformed case. The big difference will come in the action of the \( \text{SU}(2) \) transformations. As derived in \cite{10}, the infinitesimal variations generated by the (left) \( \text{SU}(2) \) rotations on the \( \text{SL}(2, \mathbb{C}) \) phase space are given by the following re-scaled Poisson brackets with an arbitrary observable \( f \):

\[
\delta_v f = -\lambda^{-2} \kappa^{-1} \{ 2 \epsilon_z \lambda^2 + \epsilon_- \lambda z + \epsilon_+ \lambda \bar{z}, f \}. \tag{36}
\]

This comes from finite \( \text{SU}(2) \) transformations on triangular matrices:

\[
\ell \mapsto \ell(v) = v \ell v^{-1}, \tag{37}
\]

where \( v' \in \text{SU}(2) \) is a priori different from \( v \) and compensates for the fact that triangular matrices are not stable under conjugation by \( \text{SU}(2) \) group elements. For infinitesimal transformations, these group elements read:

\[
v \sim_\ell \llbracket \! \llbracket \llbracket + i \epsilon \cdot \vec{\sigma} = \llbracket \! \llbracket + i \begin{pmatrix} \epsilon_z & \epsilon_- \\ \epsilon_+ & \epsilon_z \end{pmatrix}, \quad v' \sim_\ell \llbracket \! \llbracket \llbracket + i \epsilon' \cdot \vec{\sigma} \quad \text{with} \quad \epsilon'_\pm = \lambda^{-2} \epsilon_\pm, \quad \epsilon'_z = \epsilon_z + \frac{1}{2} (\lambda^{-1} \epsilon_- + \lambda^{-1} \epsilon_+) \tag{38}
\]

We look for a new spinor \( t^{1/2} \), or in short \( t \), that transforms covariantly under \( \text{SU}(2) \), that is that has the correct infinitesimal variations under left \( \text{SU}(2) \) rotations as a spin-\( \frac{1}{2} \) vector:

\[
|t \rangle \mapsto \frac{v \in \text{SU}(2)}{v \sim_\ell \llbracket \! \llbracket} v |t \rangle \sim |t \rangle + i \begin{pmatrix} \epsilon_z t_0 + \epsilon_- t_1 \\ \epsilon_+ t_0 + \epsilon_+ t_1 \end{pmatrix}. \tag{39}
\]

This is translated in the following required Poisson bracket identities:

\[
-\lambda^{-2} \kappa^{-1} \{ \lambda^2, t_0 \} = \frac{1}{2} t_0, \quad -\lambda^{-2} \kappa^{-1} \{ \lambda^2, t_1 \} = -\frac{1}{2} t_1, \quad -\lambda^{-2} \kappa^{-1} \{ \lambda z, t_0 \} = i t_1, \quad -\lambda^{-2} \kappa^{-1} \{ \lambda z, t_1 \} = 0, \quad -\lambda^{-2} \kappa^{-1} \{ \lambda \bar{z}, t_0 \} = 0, \quad -\lambda^{-2} \kappa^{-1} \{ \lambda \bar{z}, t_1 \} = i t_0. \tag{40}
\]
One can solve these equations explicitly and one finds two independent spinor solutions, which are simply a rescaled \( \zeta^\kappa \) spinor and its dual spinor:

\[
|t\rangle = \begin{pmatrix} e^{\frac{2N\kappa}{k}} \zeta_0^\kappa \\ -e^{-\frac{2N\kappa}{k}} \zeta_1^\kappa \end{pmatrix}, \quad |\bar{t}\rangle = \begin{pmatrix} -\bar{t}_1 \\ \bar{t}_0 \end{pmatrix} = \begin{pmatrix} e^{\frac{2N\kappa}{k}} \zeta_0^\kappa \\ e^{-\frac{2N\kappa}{k}} \zeta_1^\kappa \end{pmatrix}.
\]  

These new spinor components satisfy the following Poisson brackets:

\[
\{t_0, t_1\} = \frac{i\kappa}{2} t_0 t_1, \quad \{\bar{t}_0, \bar{t}_1\} = -\frac{i\kappa}{2} \bar{t}_0 \bar{t}_1, \quad \{t_0, \bar{t}_1\} = \{\bar{t}_0, t_1\} = 0,
\]

\[
\{\bar{t}_0, t_0\} = i\kappa (-\frac{1}{2}|t_0|^2 + e^{\frac{2}{N}}), \quad \{\bar{t}_1, t_1\} = i\kappa (\frac{1}{2}|t_1|^2 + e^{-\frac{2}{N}}).
\]  

Let us underline that this algebra does not completely close since there are the \( e^{\pm \frac{2}{N}} \) terms\(^1\). We compute the new rank-one Hermitian matrix \( |t\rangle \langle t| \) and compare it to the matrix \( T = \ell \ell^\dagger \):

\[
|t\rangle \langle t| = \begin{pmatrix} |t_0|^2 & t_0 \bar{t}_1 \\ \bar{t}_0 t_1^* & |t_1|^2 \end{pmatrix} = \begin{pmatrix} e^{\frac{2N}{k}} - \lambda^2 & -\lambda \sigma \\ -\lambda \sigma & e^{\frac{2N}{k}} - (\lambda^2 + |z|^2) \end{pmatrix} = e^{\frac{2N}{k}} \mathbb{I} - \ell \ell^\dagger.
\]  

This means that the two spinors, \( |t\rangle \) and its dual \( |\bar{t}\rangle \), are the two eigenvectors of the Hermitian matrix \( T = \ell \ell^\dagger \). We usually project the \( T \) matrix onto the Pauli matrices to get the SU(2)-covariant 3-vector \( \vec{T} \) as follows:

\[
T_0 = \frac{1}{2\kappa} \text{Tr} \ell \ell^\dagger = \frac{1}{2\kappa} (\lambda^2 + \lambda^{-2} + |z|^2) = \frac{1}{\kappa} \cosh \frac{kN}{2},
\]

\[
T_\ell = \frac{1}{2\kappa} \text{Tr} \ell \ell^\dagger \sigma, \quad T_3 = \frac{1}{2\kappa} (\lambda^2 - \lambda^{-2} - |z|^2), \quad T_+ = \frac{1}{\kappa} \lambda z, \quad T_- = \frac{1}{\kappa} \lambda \sigma.
\]

\[
T = \kappa (T_0 \mathbb{I} + \vec{T} \cdot \sigma).
\]

Moreover, due to the fact that \( \ell \) belongs to SL(2, \text{C}) and that its determinant is normalized to one, we have a very simple expression for the inverse of the \( T \)-matrix:

\[
\kappa^2 (T_0^2 - \vec{T}^2) = \det T = \det \ell \ell^\dagger = 1 \quad \Rightarrow \quad T^{-1} = \kappa (T_0 \mathbb{I} - \vec{T} \cdot \sigma) = T^s,
\]  

which we recognize as simply switching the sign of the 3-vector \( \vec{T} \) and thus implementing the orientation flip introduced in the undeformed case. With these conventions, we can express the components of \( |t\rangle \langle t| \) in terms of the vector \( \vec{T} \):

\[
\langle t|t\rangle = 2e^{\frac{2N}{k}} - 2\kappa T_0 = 2 \sinh \frac{kN}{2}, \quad \langle t|\bar{t}\rangle = -2\kappa \vec{T},
\]

We summarize the relation between the spinor \( t \) and the matrix \( T \) by the formulas:

\[
|t\rangle \langle t| = e^{\frac{2N}{k}} T - T^{-1} = e^{-\frac{2N}{k}} T + T^{-1}
\]

\[
|\bar{t}\rangle \langle \bar{t}| = e^{\frac{2N}{k}} T^{-1} - T = e^{-\frac{2N}{k}} T + T^{-1}
\]

All these objects all transform as follows under SU(2) transformations:

\[
\ell \rightarrow v \ell v^{-1} \rightarrow \left( \begin{array}{c} T \\ vT^{-1} \end{array} \right) \rightarrow |t\rangle \rightarrow \langle t| \langle \bar{t}\rangle \rightarrow v^{-1} \cdot \bar{t}.
\]  

The 3-vector \( \vec{T} \) could be seen as the analogue of the flux \( \vec{X} \) in the flat case, given in 4. Indeed, the vector \( \vec{T} \) appears naturally in the analysis of the deformed phase space in 16. It allows to recover some information about the

---

\(^1\) We can obtain a closed algebra if we rescale our spinors \( t_\pm, \bar{t}_\pm \) by \( e^{\pm \frac{N}{2}} \). Such rescaled components are then the exact classical analogue of the quantum spinor variables used in 13, provided we identify \( t_0 \equiv t_- \), \( t_1 \equiv t_+ \) and so on.
discrete geometry, such as the hyperbolic cosine law or the flatness constraint [16]. However, it is not sufficient, we also need another vector $\hat{T}_{op}$ to recover this information. $\hat{T}_{op}$ is a vector that transforms under the deformed SU(2) transformations $v'$ as given in [38]. To reconstruct $\hat{T}_{op}$, we need therefore to introduce another type of spinor, a "braided-covariant" spinor $|\tau\rangle$, which transforms with $v'$ and not $v$ under the SU(2) action:

$$|\tau\rangle = \ell^{-1}|t\rangle = \left(\begin{array}{cc} \lambda^{-1} & 0 \\ -z & \lambda \end{array}\right) \left(\begin{array}{c} e^{\frac{s\kappa N}{2}} \bar{\zeta}_0^\kappa \\ -e^{-\frac{\kappa N}{2}} \zeta_1^\kappa \end{array}\right) = e^{\frac{s\kappa N}{2}} \left(\begin{array}{c} \zeta_0^\kappa \\ -e^{\frac{s\kappa N}{2}} \zeta_1^\kappa \end{array}\right),$$

(49)

which satisfies the new identity in terms of $T_{op} = \ell\ell'$:

$$|\tau\rangle\langle\tau| = e^{\frac{s\kappa N}{2}} (\ell\ell')^{-1} = e^{\frac{s\kappa N}{2}} (2 \cosh \frac{\kappa N}{2} - \ell\ell') = e^{\frac{s\kappa N}{2}} (\ell\ell')^{-1},$$

(50)

$$\langle\tau|\tau\rangle = e^{\frac{s\kappa N}{2}} \text{Tr}(e^{\frac{s\kappa N}{2}} (\ell\ell')) = e^{\frac{s\kappa N}{2}} \langle t|t\rangle = 2e^{\frac{s\kappa N}{2}} \sinh \frac{\kappa N}{2} = e^{\kappa N} - 1$$

(51)

This allows to decompose this matrix and express it in terms of the 3-vector $\hat{T}_{op}$:

$$T_{op} = \frac{1}{2\kappa} \text{Tr}(\ell\ell') = T_0, \quad \hat{T}_{op} = \frac{1}{2\kappa} \text{Tr}(\ell\ell') \hat{\sigma}, \quad \langle\tau|\hat{\sigma}|\tau\rangle = 2\kappa e^{\frac{s\kappa N}{2}} \hat{T}_{op},$$

(52)

And we give all the relations:

$$e^{-\frac{s\kappa N}{2}} |\tau\rangle\langle\tau| = e^{\frac{s\kappa N}{2}} I - T_{op} = -e^{-\frac{s\kappa N}{2}} I + T_{op}^{-1}$$

$$e^{-\frac{s\kappa N}{2}} |\tau\rangle\langle\tau| = e^{\frac{s\kappa N}{2}} I - T_{op}^{-1} = -e^{-\frac{s\kappa N}{2}} I + T_{op}$$

(53)

Let us point out the useful identity relating the dual of both covariant and braided-covariant spinors:

$$\ell^{-1}|t\rangle = e^{-\frac{s\kappa N}{2}} |\tau\rangle.$$

This new spinor clearly transforms under $v'$:

$$|\tau\rangle = \ell^{-1}|t\rangle \quad \quad v \in SU(2) \quad \quad (v\ell v'^{-1})^{-1} (v |t\rangle) = v' \ell^{-1} |t\rangle = v' |\tau\rangle,$$

(55)

and one can check that we recover the correct infinitesimal variations as prescribed by the expression of the modified parameter $c'$ given in [38].

Finally, let us conclude this section with the brackets between the components of the spinor $\tau$ and its complex conjugate:

$$\{\tau_0, \tau_1\} = -\frac{i\kappa}{2} \bar{\tau}_0 \tau_1, \quad \{\bar{\tau}_0, \bar{\tau}_1\} = \frac{i\kappa}{2} \bar{\tau}_0 \bar{\tau}_1, \quad \{\tau_0, \bar{\tau}_1\} = -\frac{i\kappa}{2} \tau_0 \bar{\tau}_1, \quad \{\bar{\tau}_0, \tau_1\} = +\frac{i\kappa}{2} \bar{\tau}_0 \tau_1,$$

$$\{\bar{\tau}_0, \tau_0\} = ik \kappa e^{\kappa N_0} = ik (1 + |\tau_0|^2), \quad \{\tau_1, \bar{\tau}_1\} = ik \kappa e^{\kappa N} = ik (1 + |\tau_0|^2 + |\tau_1|^2).$$

(56)

IV. THE TILDED SECTOR - AN EXACT COPY OF THE STRAIGHT SECTOR

We repeat the same spinor construction for the tilded sector $\tilde{\ell}$ since the Poisson algebra of $\hat{\lambda}$ and $\tilde{z}$ is exactly the same as the one of $\lambda$ and $z$. We thus introduce a new spinor $\tilde{\zeta}$ and its $\kappa$-deformed version $\tilde{\zeta}^\kappa$, from which we define the components of the new tilded triangular matrix $\tilde{\ell}$:

$$\hat{\lambda} = \exp(-\frac{\kappa}{4}(\tilde{N}_0 - \tilde{N}_1)), \quad \tilde{z} = \tilde{\zeta}_0^\kappa \tilde{\zeta}_1^\kappa.$$

(57)

These satisfy the same Poisson brackets as in [38]:

$$\{\tilde{\lambda}, \tilde{z}\} = \frac{i\kappa}{2} \tilde{\lambda} \tilde{z}, \quad \{\tilde{\lambda}, \tilde{\bar{z}}\} = -\frac{i\kappa}{2} \tilde{\lambda} \tilde{\bar{z}}, \quad \{\tilde{z}, \tilde{\bar{z}}\} = i\kappa \left(\tilde{\lambda}^2 - \tilde{\bar{z}}^2\right).$$

(58)

We define the new spinor $|\tilde{t}\rangle$ as:

$$|\tilde{t}\rangle = \left(\begin{array}{c} e^{\frac{s\kappa N}{2}} \tilde{\zeta}_0^\kappa \\ -e^{-\frac{s\kappa N}{2}} \tilde{\zeta}_1^\kappa \end{array}\right), \quad |\tilde{\ell}\rangle\langle\tilde{t}| = \left(\begin{array}{cc} e^{\frac{s\kappa N}{2}} - \tilde{\lambda}^2 & -\tilde{\lambda} \tilde{\bar{z}} \\ -\tilde{\lambda} \tilde{z} & e^{\frac{s\kappa N}{2}} - (\tilde{\lambda}^2 + |\tilde{z}|^2) \end{array}\right) = e^{\frac{s\kappa N}{2}} I - \tilde{\ell}\tilde{t} = e^{\frac{s\kappa N}{2}} I - \tilde{T}.$$  

(59)
FIG. 2: The spinors live at the vertices of the ribbon. We can read off the mappings between spinors, $|t\rangle = \ell |\tau\rangle$ and $|\tilde{t}\rangle = \tilde{\ell} |\tilde{\tau}\rangle$ respectively for the straight and tilded sectors separately, and $|\tau\rangle \propto u |\tilde{t}\rangle$ and $|\tilde{\tau}\rangle \propto \tilde{u} |t\rangle$ for the SU(2) holonomies relating the two sectors. Notice that we have to take the dual spinors, which we haven’t represented in the diagram. This graphical representation is consistent with the realization of the symmetries (left rotation in this case) as described in Fig. 3.

As before, all these objects transform covariantly under the suitable SU(2) transformations, that is for representation is consistent with the realization of the symmetries (left rotation in this case) as described in Fig. 3.

We also introduce the “braided-covariant” spinor $\tilde{\tau}$,

$$|\tilde{\tau}\rangle = \tilde{\ell}^{-1} |\tilde{\ell}\rangle = \begin{pmatrix} \tilde{\lambda}^{-1} & 0 \\ -\tilde{z} & \tilde{\lambda} \end{pmatrix} \begin{pmatrix} e^{\frac{\pi}{2} N_0} \tilde{\xi}_0 \\ -e^{-\pi N_0} \tilde{\xi}_1 \end{pmatrix} = e^{\nu N_0} \begin{pmatrix} \tilde{\xi}_0 \\ -e^{\pi N_0} \tilde{\xi}_1 \end{pmatrix},$$

which transforms as $|\tilde{\tau}\rangle \rightarrow w |\tilde{\tau}\rangle$ under the same SU(2) transformations. It allows to recover the vector and matrix $\tilde{T}^\text{op}$:

$$|\tilde{\tau}\rangle \langle \tilde{\tau}| = e^{\frac{\pi}{2} \tilde{X}} (\tilde{\ell} \tilde{\ell})^{-1} - \mathbb{I} = e^{\frac{\pi}{2} \tilde{X}} (e^{\frac{\pi}{2} \tilde{X}} - \tilde{\ell} \tilde{\ell}) = e^{\frac{\pi}{2} \tilde{X}} (e^{\frac{\pi}{2} \tilde{X}} - \tilde{T}^\text{op}).$$

The Poisson commutation relations between the different spinor components are essentially the same as in (42) and (50), putting some tilde everywhere. We can also consider the cross terms, that is the Poisson commutation relations between the spinors and their tildes alter ego.

$$\{t_A, \tilde{t}_B\} = \{t_A, \tilde{\tau}_B\} = \{\tilde{t}_A, \tau_B\} = 0.$$  (63)

Taking all these to be zero ensures the commutation relations $\{\ell_1, \ell_2\} = 0$, as obtained in (25).

V. Q-DEFORMED HOLONOMY RECONSTRUCTION

Now starting from $\ell$ and $\tilde{\ell}$, i.e the 3-vectors $\tilde{T}$ and $\tilde{T}$, we would like to reconstruct the SU(2) holonomies $u$ and $\tilde{u}$. However, as in the undeformed case, it is impossible to fully reconstruct the holonomy $g$ from the two 3-vectors $X$ and $\tilde{X}$. Indeed, we have an undetermined phase, corresponding to a free rotation around the $\tilde{X}$ axis. Nevertheless, using the spinor variables freezes that extra phase and we can explicitly reconstruct the whole holonomy $g$ from $z$ and $\tilde{z}$ as shown in section I. Similarly here, we will use the spinors $t$ and $\tilde{t}$, from which we have already shown how to reconstruct the triangular matrices $\ell$ and $\tilde{\ell}$, and we will see below how to derive the SU(2) holonomies $u$, $\tilde{u}$ and thus ultimately the SL(2, C) group element $D$.

More precisely, from the triangular matrices $\ell$ and $\tilde{\ell}$, one builds the following Hermitian matrices:

$$T = \ell \ell^\dagger, \quad \tilde{T} = \tilde{\ell} \tilde{\ell}^\dagger, \quad T^\text{op} = \ell^\dagger \ell, \quad \tilde{T}^\text{op} = \tilde{\ell}^\dagger \tilde{\ell},$$

whose projection on the Pauli matrices define the 3-vectors $\tilde{T}$ and $\tilde{T}$, that live on the two ends of one edge. The fact that $\ell$ and $\tilde{\ell}$ both come from the same SL(2, C) group element $D$ decomposed following the left and right Iwasawa decomposition as $D = \ell u = \tilde{u}^{-1} \tilde{\ell}^{-1}$ with $u$, $\tilde{u} \in$ SU(2) implies that those 3-vectors are related by the SU(2) holonomies (obtained from the expression of $DD^\dagger$ and $D^\dagger D$):

$$\begin{align*}
T &= \tilde{u}^{-1} \tilde{T}^\text{op}^{-1} \tilde{u} \\
\tilde{T} &= -\tilde{u} \triangleright \tilde{T}^\text{op} \quad , \quad u^{-1} T^\text{op} u = \tilde{T}^{-1} \\
u \triangleright \tilde{T}^\text{op} &= -\tilde{T}.
\end{align*}$$

(64)
We now consider both left and right SU(2) transformations:

$$D \rightarrow vDw^{-1} = v\ell u w^{-1} = v\tilde{u}^{-1} \tilde{\ell}^{-1}w^{-1}.$$ 

The left transformations read:

$$D \rightarrow vD = \begin{cases} v\ell u = (v\ell v^{-1})(v'u) \\ v\tilde{u}^{-1} \tilde{\ell}^{-1} = (\tilde{u}v^{-1})^{-1} \tilde{\ell}^{-1} \end{cases}$$

They affect $\ell$ but not $\tilde{\ell}$. On the other hand, right transformations read:

$$D \rightarrow Dw^{-1} = \begin{cases} \ell(w^{-1}) \\ \tilde{\ell}^{-1}w^{-1} = (w'\tilde{u})^{-1} (w\tilde{\ell}w^{-1})^{-1} \end{cases}$$

and likewise affect only $\tilde{\ell}$ while leaving $\ell$ unchanged. The SU(2) holonomies have slightly skewed transformations since they are covariant on one side and braided-covariant on the other:

$$\left| u \rightarrow v'u w^{-1} \atop \tilde{u} \rightarrow w\tilde{u} v^{-1} \right.$$

(65)

We are now ready to describe how to define the SU(2) holonomies $u$ and $\tilde{u}$ from the spinor variables, using their transformation properties under the SU(2) action as guide. First, one must impose a norm-matching condition, $N = \tilde{N}$, or equivalently $T_0 = \tilde{T}_0$ or in terms of spinors $\langle t|\ell \rangle = (\ell|\tilde{t})$. Starting with $u$, its natural definition is mapping the spinors $|\ell\rangle, |\tilde{t}\rangle$ to $|\tau\rangle, -|\tau\rangle$:

$$u = \frac{|\tau\rangle\langle \ell| - |\tau\rangle\langle \tilde{t}|}{\sqrt{\langle \tau|\tau\rangle \langle \ell|\ell \rangle}}.$$  

(66)

We first check that this ensures the correct parallel transport:

$$\frac{u|\ell\rangle\langle \ell| u^{-1}}{|\ell|\langle \ell|} = \frac{|\tau\rangle|\tau\rangle}{\langle \tau|\tau\rangle} \quad \implies \quad u\tilde{T}_0 u^{-1} = T^{op}.$$ 

Similarly, we define the SU(2) holonomy $\tilde{u}$ for the tilded sector as the unitary group element mapping the basis $|\ell\rangle, |\tilde{t}\rangle$ to $-|\tilde{\tau}\rangle, |\tilde{\tau}\rangle$:

$$\tilde{u} = \frac{|\tilde{\tau}\rangle\langle \ell| - |\tilde{\tau}\rangle\langle \tilde{t}|}{\sqrt{\langle \tilde{\tau}|\tilde{\tau}\rangle \langle \ell|\ell \rangle}}.$$  

(67)
Once again, this ensures the expected parallel transport:

\[ \bar{u} |t\rangle \langle t| \bar{u}^{-1} = \frac{|\bar{\tau}|}{|\bar{\tau}|} \implies \bar{u} T^{-1} = T^{op}^{-1}. \]

We can further check that \( t^{-1} \bar{u}^{-1} \bar{\ell}^{-1} u^{-1} = 1 \), by using the maps between the covariant spinors and dual and their braided-covariant counterparts, and that the straight and tilded sectors indeed define the same \( \text{SL}(2, \mathbb{C}) \) group element \( D = tu = (\bar{t} \bar{u})^{-1} \).

Finally, one can compute the Poisson brackets of the components of \( u \) and \( \bar{u} \), and check that it provides the correct phase space structure. Let us consider the \( D \) and its subspace \( \mathcal{S}_{\kappa} \), and that the \( \bar{t} \) and \( t \) in the \( \bar{t} \)-decoupled variables (i.e. the tilded variables) as well between these two sets of variables (63). Being careful to the norm factors, which are actually rather important and not to be neglected, we compute the Poisson brackets of the components of \( u \) with itself and find:

\[ \{ \alpha, \beta \} \simeq -\frac{i \kappa}{2} \alpha \beta, \quad \{ \alpha, \bar{\beta} \} \simeq -\frac{i \kappa}{2} \alpha \bar{\beta}, \quad \{ \alpha, \bar{\alpha} \} \simeq i \kappa |\beta|^2, \quad \{ \beta, \bar{\beta} \} \simeq 0, \]  

which are weak equalities up to assuming the norm-matching constraint \( N - \bar{N} = 0 \). This is valid since all these variables \( \ell, \bar{\ell}, u, \bar{u} \) have a vanishing Poisson bracket with that constraint. These are the expected Poisson brackets for the \( \text{SU}(2) \) holonomy \( u \) from the \( \text{SL}(2, \mathbb{C}) \) phase space formulas. Proceeding similarly, it is straightforward to check that we recover the whole phase space with the correct brackets between the left decomposition variables, between the right decomposition variables (i.e. the tilded variables) as well between these two sets of variables (63).

We have therefore the following theorem.

**Theorem V.1.** Consider \( \mathcal{S}_{\kappa} \subset \mathbb{C}^2 \) the phase space given in terms of the following (non-canonical) Poisson brackets \( (t_A \in \mathbb{C}^2) \)

\[ \{ t_0, t_0 \} = -\frac{i \kappa}{2} |t_0|^2 + 2e^{\frac{3}{2}N}, \quad \{ t_1, t_1 \} = \frac{i \kappa}{2} (|t_1|^2 + 2e^{-\frac{3}{2}N}), \]

\[ \{ t_0, t_1 \} = \frac{i \kappa}{2} t_0 t_1, \quad \{ \bar{t}_0, \bar{t}_1 \} = -\frac{i \kappa}{2} \bar{t}_0 \bar{t}_1, \quad \{ t_0, \bar{t}_1 \} = \{ \bar{t}_0, t_1 \} = 0, \]

and its subspace \( \mathcal{S}_{\kappa^*} \subset \mathbb{C}^2, \mathbb{C}^2 \), \( \{ 0|t \} = 0 \} \).

The symplectic reduction \( \mathcal{P}_{\kappa} = (\mathcal{S}_{\kappa^*} \times \mathcal{S}_{\kappa^*}) / M \) of the phase space \( \mathcal{S}_{\kappa^*} \times \mathcal{S}_{\kappa^*} \) (parametrized by \( (t_A, \bar{t}_A) \)) by the matching norm condition \( M = \{ |t| = |\bar{t}| \} = 0 \) is isomorphic to the phase space \( \text{SL}(2, \mathbb{C}) \) which Poisson structure is

\[ \{ D_1, D_2 \} = -r D_1 D_2 - D_1 D_2 r^{-1}, \quad D \in \text{SL}(2, \mathbb{C}), \quad r = \frac{\kappa}{4} \sum_i \tau_i \otimes \sigma_i, \quad \tau_i = i(\sigma_i - \frac{1}{2}[\sigma_3, \sigma_i]). \]
This theorem is the classical analogue of the Schwinger-Jordan representation of $U_q(su(2))$ in terms of harmonic oscillators \cite{31,52}. Note furthermore that we can relate $S_\kappa$ to the undeformed phase space $\mathbb{C}^2$, as we have recalled in \cite{29}. Hence there is a symplectomorphism between the undeformed phase space $\mathbb{C}^2$ and $S_\kappa$. This symplectomorphism can then be naturally extended between the spaces $P = (\mathbb{C}^2 \times \mathbb{C}^2)/\mathcal{M}$ and $P_n = (S_{\kappa^n} \times S_{\kappa^n})/\mathcal{M}$. We recall that $P$ is the phase space behind the (flat) twisted geometries construction and is such that $P \sim T^*SU(2)$ \cite{18,20}. Hence we have recovered in a new manner the well-known fact that $T^*SU(2)$ and $SL(2, \mathbb{C})$ are symplectomorphic as phase spaces (while still obviously different as groups).

**VI. TOWARDS HYPERBOLIC TWISTED GEOMETRIES**

We would like to use the spinor phase space developed above to parametrize the hyperbolic deformation of twisted geometries for loop gravity. We consider a graph, with oriented edges and chosen order around each vertex (i.e. all the attached edges are ordered). We attach spinor variables to each half-edge: around each vertex $\vartheta$, for each attached edge $e \ni \vartheta$, we define a spinor $\zeta_{e,\vartheta} \in \mathbb{C}^2$ with canonical Poisson brackets and then as developed previously spinors $\zeta_{e,\vartheta}$, $\ell_{e,\vartheta}$ and $\tau_{e,\vartheta}$ satisfying deformed Poisson brackets. Then for each edge we have a pair of spinors, one at each end. We naturally associate the source vertex to the straight sector and the target vertex to the tilded sector: we write for short $\zeta_e = \zeta_{e,s(e)}$ at the target vertex $\vartheta = s(e)$ and $\zeta_e = \zeta_{e,t(e)}$ at the source vertex $\vartheta = t(e)$. Assuming norm-matching conditions along the edges,

$$M_e = \langle \zeta_{e,s}|\zeta_{e,s} \rangle - \langle \zeta_{e,t}|\zeta_{e,t} \rangle = \langle \zeta_{e}|\zeta_{e} \rangle - \langle \zeta_{e}|\zeta_{e} \rangle = 0\,,$$

we can define all the group elements $\ell_e, \ell'_e \in SB(2, \mathbb{C})$ and $u_e, u'_e \in SU(2)$ along the edges. All of these variables have vanishing Poisson brackets with the norm-matching constraint. The norm-matching constraint generates a $U(1)$ action on the spinors, multiplying $\zeta_e$ and $\bar{\zeta}_e$ by opposite phases. The group elements $\ell'$s and $u'$s are all invariant under such phase shifts. And this leads to one copy of the $SL(2, \mathbb{C})$ phase space on each edge with the group element $D_e = \ell_e u_e = (\ell'_e u'_e)^{-1}$ and Poisson brackets given in terms of the classical r-matrix.

Up to now, we have simply introduce a re-parametrization of the standard phase space $(\mathbb{C}^2)^{2E}/U(1)^E$, where we are taking the symplectic quotient by the matching conditions along every edge, in terms of the non-trivial and non-canonical variables $\ell_e, \ell'_e, u_e, u'_e$. The big difference with the standard spinor networks and twisted geometries is the deformed action of the $SU(2)$ gauge group at the vertices. Indeed the initial canonical spinors $\zeta_e, \bar{\zeta}_e$ do not transform simply as spin-1/2 vectors under $SU(2)$ transformations. It is instead the non-canonical spinors $\ell_e, \ell'_e$ that transform linearly under the action of $SU(2)$. This $SU(2)$ action can be in principle transposed on the canonical spinors $\zeta_e, \bar{\zeta}_e$, it is highly non-linear and the explicit expression is rather cumbersome. Taking this into account, it is not obvious that the matching conditions $M_e = \langle \zeta_{e}|\zeta_{e} \rangle - \langle \zeta_{e}|\zeta_{e} \rangle = 0$ are invariant under the $SU(2)$ action. There are nevertheless exactly equivalent to the obviously $SU(2)$-invariant constraint written in terms of the non-canonical spinors $\ell'$s,

$$M_e = \langle \ell_e|\ell_e \rangle - \langle \ell'_e|\ell'_e \rangle = 0\,.$$

Actually the new setting is even more subtle. In order to define the $SU(2)$ action at a vertex $\vartheta$, we need to consider the chosen ordering of the edges around it. Let’s number these edges $e_i$ with $i = 1..n$. As shown and explained in \cite{16}, assuming that all the edges are oriented outward, the $SU(2)$ transformations are generated by the deformed closure constraints (or Gauss law in the context of loop gravity) $G_{\vartheta} = \ell_1..\ell_n = I$. The product is obviously non-abelian and the ordering of the triangular matrices matters. More precisely, the $SU(2)$ transformation for one (half-)edge $e_i$ will get braided by all the previous $\ell_k$ for $k < i$. This reads for a transformation $v \in SU(2)$;

$$\begin{align*}
\ell_1 & \rightarrow v_1 \ell_1 v_1^{-1} \\
\ell_2 & \rightarrow v_1 \ell_2 v_2^{-1} \\
\ell_i & \rightarrow v_{i-1} \ell_i v_i^{-1} \\
\ell_n & \rightarrow v_{n-1} \ell_n v_n^{-1}
\end{align*} \quad (69)$$

where the last $v'$ factor is equal to the initial $SU(2)$ transformation $v_n = v$ due to the condition $\ell_1..\ell_n = I$ itself. As shown in \cite{16}, these $SU(2)$ transformations are Poisson-generated by the Hermitian square of the closure constraints $G_{\vartheta}^\dagger G_{\vartheta}$ as:

$$\delta_v f = -\kappa^{-1} \prod_{k=1}^n \lambda_k^{-2} \{ \text{Tr} V G_{\vartheta}^\dagger G_{\vartheta} , f \} \quad \text{with} \quad v \sim I + i \epsilon \cdot \vec{\sigma} = I + i \left( \begin{array}{cc} \epsilon_- & \epsilon_+ \\ \epsilon_+ & \epsilon_- \end{array} \right) , \quad V = \left( \begin{array}{cc} 2\epsilon_z & \epsilon_- \\ \epsilon_+ & 0 \end{array} \right) , \quad (70)$$
FIG. 4: On the left side, we have a standard spinor network. We flatten the graph to encode $T^*SU(2)$ as ISO(3). In this case, $\tilde{u}_i = u_i^{-1}$, and we have the same spinors standing at the extremities of each ribbon. On the right side, we deform ISO(3) into SL(2, $\mathbb{C}$). Hence the braided covariant spinors appear: the extremities of the ribbon have both a covariant and a braided covariant spinor.

for infinitesimal transformation $v \sim I$ with $\epsilon \sim 0$. For $n = 1$, we recover the infinitesimal transformations already given in [36]. If an edge $e_k$ is incoming instead of outgoing, one simply replaces $\ell_k$ by $\tilde{\ell}_k$ in the closure constraint and nothing else changes. The interested reader will find detailed explanations and proofs for this in [16]. We can summarize all these structures by a graphical representation of our deformed spin network as ribbon graphs, as illustrated on Fig. 4.

Moreover, the previous work [16] further provided a geometrical interpretation for the closure constraints at least in a (2+1)-dimensional setting. Considering trivalent graphs, one can map uniquely a triplet of triangular matrices satisfying the closure $\ell_1 \ell_2 \ell_3 = I$ onto a hyperbolic triangle (up to translations) such that the $\ell$’s are interpreted as the “hyperbolic normals” to the triangle’s edges. Then, assuming a (SU(2)-invariant) flatness condition around every loop (in terms of the SU(2) holonomies $u_e$ and $\tilde{u}_e$), one could glue these hyperbolic triangles consistently together within the $3$-hyperboloid (of unit time-like vectors in the 4d Minkowski space-time $\mathbb{R}^4$). However, a (3+1)-d geometric interpretation of the closure constraints, and thus of these deformed spinor networks, in terms of hyperbolic tetrahedra and polyhedra has not yet been worked out. This is a highly non-trivial mathematical issue and we leave for future investigation. This would provide us with hyperbolic twisted geometries as a generalization to non-vanishing cosmological constant of the standard twisted geometries describing the kinematical configurations of loop gravity.

Discussion

We have shortly reviewed the deformed phase space for loop gravity and the associated deformed action of SU(2) introduced in [16] in order to represent discrete hyperbolic surfaces and to yield directly spin networks for $U_q(U(2))$ upon canonical quantization [17]. Here, we have introduced spinor variables with canonical Poisson brackets as Darboux coordinates for this phase space and we have defined non-canonical spinor variables that allow to represent the deformed phase space on a given graph as a spinor network. The resulting structures on the graph are a pair of spinors on each edge, one attached to each of its ends, provided with norm-matching constraints for every edge and deformed closure constraints for every vertex. This ensures that one can reconstruct the full SL(2, $\mathbb{C}$) phase space on each edge, given in terms of a group element $D_e = \ell_e u_e \in SL(2, \mathbb{C}) \sim SB(2, \mathbb{C}) \cong SU(2)$ together with a Poisson bracket defined in terms of the classical $r$-matrix of $sl_2$, and that we have a local SU(2) invariance at each vertex.

Just like the use of spinor variables for twisted geometries in standard loop quantum gravity (e.g. [20, 21]), we hope that this spinorial formalism for the hyperbolically-deformed loop gravity phase space will similarly shed light on the construction of observables and the interpretation of the deformed phase space as 2d and 3d hyperbolic geometries, at the classical level. We expect that it should provide some insights on the definition of coherent states at the quantum level. This work should be considered as setting up the framework for a larger program whose next steps would be:

- Identify the SU(2)-invariant observables at the vertices in terms of suitable scalar products between spinors and investigate the deformed $u(N)$ structure of their Poisson algebra. This should be the classical analogue of the $U_q(u(N))$ structure found in the quantum case [13].
- Build on the work [12, 13] and investigate the relation between the classical flatness constraints and the spinfoam dynamics for 3d quantum gravity with negative cosmological constant through the analysis of recursion relations for the $q$-deformed $6j$-symbols using spinor operators, as done in [27].
• Study the SU(2) flatness holonomy constraint defined as $\prod u_\kappa = I$ in the previous work [16], analyze its expansion in terms of the deformation parameter $\kappa$ and understand the deviations from the standard flat spinor network case and the origin of the (hyperbolic) curvature in the continuum limit.

• Extend the general construction to the spherical case, where quasi-Poisson Lie group structures will likely be the right tool [33].

• Understand the geometrical meaning of the deformed spinor network in terms of 3d geometry embedded in a 3+1d space-time and extend the construction to a deformed twistor phase space and appropriate simplicity constraints as done in the standard flat case [31, 35].

At the end of the day, we believe spinorial variables to be a very promising and relevant tool to investigate the quantization of loop gravity with a non-vanishing cosmological constant and its relation to the quantum deformation of the gauge group.
