Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company’s public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Prognostic value of maximum NEWS-2 scores in addition to ISARIC 4C scores for patients admitted to hospital with COVID-19

Dear Editor

We read with interest the article by Federico and colleagues, which found that secondary bacterial infections play a critical role in adverse outcomes for patients with severe COVID-19.1 In the United Kingdom (UK), the National Early Warning Score-2 (NEWS-2) score, consisting of an a priori weighted composition of the patient’s observations, is used routinely to monitor
patients in hospital and identify early those who may deteriorate. NEWS-2 was originally developed in a cohort of UK patients who had an underlying diagnosis of bacterial sepsis, but has been shown in previous studies to be sensitive in identifying those at risk of in-hospital cardiac arrest, unanticipated intensive care unit (ICU) admission or death. In previous work published in the Journal, we showed that in hospitalised patients with COVID-19, variability in NEWS-2 scores during hospitalisation, but not the admission NEWS-2 scores was related to mortality.

In contrast, the International Severe Acute Respiratory and Emerging Infection Consortium (ISARIC) 4C Mortality Score (referred to now as the ISARIC score) was developed specifically to predict risk of death from viral pneumonia in patients with COVID-19. Developed from a large UK cohort, the ISARIC score consists of statistically weighted composition of age, gender, comorbidities, patient’s observations, serum urea and C-reactive protein. Perhaps unsurprisingly, the ISARIC score has been shown to have a higher predictive value for mortality compared to a concomitantly calculated NEWS-2 score, since it takes into account more variables. An ISARIC score on admission is recommended as part of COVID-19 guidance in around half of UK hospitals. However, there is currently no data on whether the highest NEWS-2 scores taken during hospitalisation would be of incremental value in predicting mortality taking into account ISARIC scores following admission to hospital.

We therefore set out to investigate this issue by using a cohort of 315 consecutive patients who presented to our Acute Respiratory Unit at the University Hospitals of Leicester NHS Trust, UK between October 2020 to January 2021. Data collected and their results are shown in Table 1. The mean age of patients was 63 (standard deviation [SD] 15); most were of White ethnicity. Clinical evidence of bacterial infection was low; most had evidence of pneumonia on their chest x-ray. Most participants were given supportive oxygen, antibiotics and steroids during their hospital stay. The mean ISARIC score was 10 (SD 4); mean admission NEWS-2 score was 5 (SD 2) and the mean of the maximum NEWS-2 score recorded for each patient during admission was 9 (SD 3). Our cohort suffered significant mortality and morbidity: 33% of study participants died; 4% were admitted to ICU and length of stay was close to two weeks (mean: 13 days, SD 11).

Two logistic regression models were used to investigate the incremental value of the maximum NEWS-2 score in addition to other routinely collected clinical variables. A base model
was first constructed, using variables that were related to mortality on univariable analysis. The NEWS-2 score was then added onto the base model, in order to find the best model that predicted mortality. The new models’ cumulative discrimination compared to the base model was measured using an Area under the Receiver Operating Curve (AUROC). A 2-sided p value of ≤ 0.05 was considered statistically significant.

On univariable logistic regression analysis, admission ISARIC score, the maximum NEWS-2 score, treatment with steroids and antibiotics were related to mortality. Consistent with earlier findings, admission NEWS-2 scores was not related to all mortality. In our multivariable model, admission ISARIC score (adjusted odds ratio [aOR: 1.25, 95% confidence intervals [CI]: 1.14-1.36, p<0.001) and the maximum NEWS-2 score (aOR: 1.62, 95% CI: 1.40-1.88, p<0.001) remained independent predictors of mortality (Figure 1A). Addition of the NEWS-2 score also improved the model’s AUROC (from 0.74 to 0.85, Figure 1B). It is worth noting that our study was observational in nature, and therefore our multivariable analysis does not reflect futility of the aforementioned treatment, but rather, strength of the prognostic value of both ISARIC and NEWS-2 scores in our cohort.

In conclusion, our study has found that a combination of an admission ISARIC score, followed by NEWS-2 score monitoring most accurately predicts in-hospital mortality in hospitalised patients with COVID-19. Previous studies have only made head-to-head comparisons of different scoring systems without considering them synergistically.\textsuperscript{6,8,9} Whilst the use of NEWS-2 scores alone may have limitations because they do not account for the degree of supplemental oxygen a patient with COVID-19 may require, a high NEWS-2 score during hospitalisation continues to have important prognostic value in the prediction of mortality.\textsuperscript{10} This could be due to the possibility that NEWS-2 scores are predicting the probability of secondary bacterial sepsis, and/or cardiac arrest. Whilst we acknowledge that evidence of bacterial infection was low in our cohort, only half of our cohort had sputum/blood cultures done, possibly due to overlap in clinical syndromes between COVID-19 and bacterial infections, as well as SARS-CoV-2 aerosol generating concerns of sputum induction. With COVID-19 shifting from a pandemic to an endemic disease, increasing number of patients will have pre-existing immunity to SARS-CoV-2, either from previous exposure and/or vaccination. It is therefore reasonable to suggest that the causes of death in patients may shift from acute viral pneumonia (seen mainly in the immune naïve adults experiencing their first COVID-19 infection) to other causes, including
superadded bacterial infections or decompensation of their chronic conditions. In these circumstances, NEWS-2 scores will have an increasing role to play in identifying those who are at most risk of adverse outcomes.

Note that this study was performed during the emergence of the alpha (B.1.1.7) variant, in a mostly unvaccinated UK population (UK COVID-19 vaccination started on 8 December 2020). So this hybrid ISARIC-NEWS prognostic scoring approach may have different outcomes in the current omicron (B.1.1.529) surge in a mostly vaccinated population.

Table 1: Clinical description of the cohort

| Demographics                  | Patients |
|-------------------------------|---------|
| Age (years) – mean (SD)       | 63 (15) |
| Gender (male) – number (%)    | 203 (64%) |
| Ethnic group – number (%)     |         |
| White                         | 192 (61%) |
| Asian                         | 87 (27%)  |
| Black                         | 9 (3%)   |
| mixed/others                  | 29 (9%)  |

| Clinical characteristics      |         |
| ISARIC score – mean (SD)      | 10 (4)  |
| Admission NEWS-2 score – mean (SD) | 5 (2) |
| Maximum NEWS-2 score recorded during hospitalisation – mean (SD) | 9 (3) |

| Blood/sputum culture done – n (%) | 147 (46%) |
| Pathogen in those with culture   | 14 (9%)  |
| Coliform                        | 5 (3%)   |
| *Staphylococcus aureus*         | 7 (5%)   |
| *Pseudomonas*                   | 2 (1%)   |
| *Stenotrophomonas maltophilia*  | 1 (1%)   |

| Findings of COVID-19 on chest x-ray – n (%) | 259 (82%) |

| Treatment                      |         |
| O2 – n (%)                     | 296 (93%) |
| Antibiotics – n (%)            | 276 (87%) |
| Dexamethasone – n (%)          | 276 (87%) |
| Remdesivir - n (%)             | 9 (3%)   |
| Tocilizumab – n (%)            | 14 (4%)  |

| Outcomes                      |         |
| ITU – n (%)                   | 12 (4%)  |
| Mortality – n (%)             | 106 (33%) |
| Length of stay – mean (SD)    | 13 (11)  |
Figure 1. A. Forest plot showing variables relating to mortality on multivariable logistic regression analysis. B. Receiver operating curves for the multivariable logistic regression model. Model A: without including the highest NEWS-2 score (variables included: antibiotic administration, steroid administration, ISARIC score). Model B: including the highest NEWS-2 score (including the same variables as shown in A).
