(Dated: February 23, 2011)

We study the evolution of matter density perturbations in Galileon cosmology where the late-time cosmic acceleration can be realized by a field kinetic energy. We obtain full perturbation equations at linear order in the presence of five covariant Lagrangians $L_i$ ($i = 1, \cdots, 5$) satisfying the Galileon symmetry $\partial\mu \phi \rightarrow \partial\mu \phi + b_\mu$ in the flat space-time. The equations for a matter perturbation as well as an effective gravitational potential are derived under a quasistatic approximation on subhorizon scales. This approximation can reproduce full numerical solutions with high accuracy for the wavelengths relevant to large-scale structures. For the model parameters constrained by the background expansion history of the Universe the growth rate of matter perturbations is larger than that in the $\Lambda$-cold dark matter model, with the growth index $\gamma$ today typically smaller than 0.4. We also find that, even on very large scales associated with the integrated-Sachs-Wolfe effect in cosmic microwave background temperature anisotropies, the effective gravitational potential exhibits a temporal growth during the transition from the matter era to the epoch of cosmic acceleration. These properties are useful to distinguish the Galileon model from the $\Lambda$-cold dark matter in future high-precision observations.

I. INTRODUCTION

The large-distance modification of gravity has received much attention as a possible explanation for the cosmic acceleration today [1]. Many modified gravitational models of dark energy have been already proposed—including those based on $f(R)$ gravity [2], scalar-tensor theories [3], Gauss-Bonnet gravity and its generalizations [4], Dvali-Gabadadze-Porrati (DGP) braneworld [5], and Galileon gravity [6]. In $f(R)$ gravity, for example, the viable models are designed to have a large mass of a scalar gravitational degree of freedom (“scalaron” [8]) in the regions of high density for the compatibility with local gravity experiments. In this case, as long as the so-called chameleon mechanism is at work, the interaction between the scalaron and baryons can be suppressed to satisfy local gravity constraints [10].

There is another mechanism to decouple the fifth force from baryons at short distances even in the absence of the scalar-field potential. Nonlinear effects of field self-interactions can allow the recovery of General Relativity (GR) inside a so-called Vainshtein radius [11]. In the DGP model a longitudinal graviton (i.e. a brane-bending mode $\phi$) gives rise to the self-interaction of the form $(r_+^2/m_{pl}) \Box \phi (\partial^\mu \phi \partial_\mu \phi)$ through the mixing with a transverse graviton, where $r_+$ is a crossover scale of the order of the Hubble radius $H_0^{-1}$ today and $m_{pl}$ is the Planck mass [12]. In the local region where the energy density $\rho$ is much larger than $r_-^{-2} m_{pl}^2$, the nonlinear self-interaction can lead to the decoupling of the field from matter. However the DGP model suffers from a ghost problem [13], in addition to the difficulty for consistency with the combined data analysis of Supernovae Ia (SN Ia) and Baryon Acoustic Oscillations (BAO) [14].

The self-interacting Lagrangian $\Box \phi (\partial^\mu \phi \partial_\mu \phi)$ appearing in the DGP model satisfies the Galileon symmetry $\partial_\mu \phi \rightarrow \partial_\mu \phi + b_\mu$ in the Minkowski background. Imposing the Galileon symmetry in the flat space-time one can show that the field Lagrangian consists of five terms $L_1, \cdots, L_5$, where the term $\Box \phi (\partial^\mu \phi \partial_\mu \phi)$ corresponds to $L_3$ [6]. In Refs. [15] these terms were extended to covariant forms in the curved space-time. Moreover one can keep the equations of motion up to the second-order, while recovering the Galileon Lagrangian in the Minkowski space-time. This property is welcome to avoid the appearance of an extra degree of freedom associated with ghosts.

In Refs. [16, 17] two of the present authors studied the cosmological dynamics of covariant Galileon theory in the presence of the terms up to $L_5$ (see Refs. [18]-[39] for related works). There exist de Sitter (dS) solutions responsible for dark energy driven by the field kinetic energy. Refs. [16, 17] also clarified the viable model parameter space in which the appearance of ghosts and instabilities of scalar and tensor perturbations can be avoided.

In the covariant Galileon cosmology the solutions finally converge to a common trajectory (tracker), which is characterized by the evolution $\dot{\phi} \propto H^{-1}$ ($H$ is the Hubble parameter) [16]. The epoch at which the solutions approach the tracker depends on the initial conditions of the variable $\tau_1 \equiv \phi_{dS} H_{dS}/(\dot{\phi} H)$, where the subscript “dS” represents the values at the dS point. For smaller initial values of $\tau_1$ the approach to the tracker, characterized by $\tau_1 = 1$, occurs later. In Ref. [16] it was shown that the combined data analysis of SN Ia, BAO, and the cosmic microwave background (CMB) shift parameter tends to favor a late-time tracking behavior around the present epoch. This comes from the fact that the dark energy equation of state $w_{DE} \simeq -2$, which corresponds to the one for the tracker during the deep matter era [16], is difficult to be compatible with a number of observations.
In order to constrain the Galileon model further, it is important to know the evolution of cosmological perturbations from the matter era to the epoch of cosmic acceleration. In particular, the modified growth of matter perturbations $\delta_m$ affects the matter power spectrum as well as the weak lensing spectrum [11]. Moreover the modification of gravity manifests itself for the evolution of the effective gravitational potential $\Phi_{\text{eff}}$ related with the integrated-Sachs-Wolfe (ISW) effect in CMB anisotropies. In this paper we shall derive the equations of cosmological perturbations in the presence of the five Galileon terms $\mathcal{L}_i$ ($i = 1, \cdots, 5$) and numerically integrate them to find observational signatures of the Galileon model. We also obtain convenient forms of the effective gravitational coupling $G_{\text{eff}}$ and the anisotropic parameter $\eta$ between two gravitational potentials, under a quasistatic approximation for the modes deep inside the Hubble radius.

This paper is organized as follows. In Sec. II we review the Galileon cosmology in the flat Friedmann-Lemaître-Robertson-Walker (FLRW) background. In Sec. III the equations of cosmological perturbations in the Galileon model are derived in the presence of nonrelativistic matter. In Sec. IV we obtain the equations for $\delta_m$ and $\Phi_{\text{eff}}$ under a quasistatic approximation on subhorizon scales. In Sec. V we present numerical results for the evolution of perturbations by integrating the full equations of motion for the wave numbers relevant to large-scale structures and CMB anisotropies. Sec. VI is devoted to conclusions.

II. BACKGROUND GALILEON COSMOLOGY

Let us consider the following action

$$ S = \int d^4x \sqrt{-g} \left[ \frac{M_{\text{pl}}^2}{2} R + \frac{1}{2} \sum_{i=1}^{5} c_i \mathcal{L}_i + p_m(\mu, s) \right], $$

where $g$ is a determinant of the space-time metric $g_{\mu\nu}$, $M_{\text{pl}} = (8\pi G)^{-1/2}$ is the reduced Planck mass (with $G$ being gravitational constant), $R$ is a Ricci scalar, and $c_i$ are constants. The five covariant Lagrangians $\mathcal{L}_i$ ($i = 1, \cdots, 5$) are given by [15]

$$
\begin{align*}
\mathcal{L}_1 &= M^3 \phi, \\
\mathcal{L}_2 &= (\nabla \phi)^2, \\
\mathcal{L}_3 &= (\Box \phi)(\nabla \phi)^2 / M^3, \\
\mathcal{L}_4 &= (\nabla \phi)^2 \left[ 2(\Box \phi)^2 - 2\phi_{\mu\nu}\phi^{\mu\nu} - R(\nabla \phi)^2 / 2 \right] / M^6, \\
\mathcal{L}_5 &= (\nabla \phi)^2 \left[ (\Box \phi)^3 - 3(\Box \phi) \phi_{\mu\nu}\phi^{\mu\nu} + 2\phi_{\mu\nu} \phi_{\nu\rho} \phi^{\mu\rho} - 6\phi_{\mu\nu} \phi^{\mu\rho} \phi^{\rho\sigma} G_{\nu\rho} / M^9 \right],
\end{align*}
$$

where $M$ is a constant having a dimension of mass, and $G_{\mu\nu}$ is the Einstein tensor. These Lagrangians respect the Galileon symmetry in the Minkowski space-time. Moreover the field equations are kept up to the second-order in time derivatives. The last term, $p_m$, represents the pressure of a perfect fluid whose energy density and equation of state are $\rho_m$ and $w = p_m / \rho_m$, respectively. The pressure depends on a chemical potential $\mu = (\rho_m + p_m) / n$ ($n$ is a number density) and an entropy per particle $s$.

Since we are interested in the evolution of matter density perturbations long after the radiation-domination, we take into account a nonrelativistic fluid ($w \approx 0$) only in the following discussion. In the FLRW space-time with the scale factor $a(t)$, the variation of the action [2] leads to the following background equations [16, 17]:

$$
\begin{align*}
3M_{\text{pl}}^2 H^2 &= \rho_{\text{DE}} + \rho_m, \\
3M_{\text{pl}}^2 H^2 + 2M_{\text{pl}}^2 \dot{H} &= -p_{\text{DE}},
\end{align*}
$$

where $H = \dot{a} / a$ is the Hubble parameter (a dot represents a derivative with respect to cosmic time $t$), and

$$
\begin{align*}
\rho_{\text{DE}} &= -c_1 M^3 \phi / 2 - c_2 \dot{\phi}^2 / 2 + 3c_3 H \dot{\phi} \phi / M^3 - 45c_4 H^2 \dot{\phi}^3 / (2M^6) + 21c_5 H^3 \dot{\phi}^4 / M^9, \\
p_{\text{DE}} &= c_1 M^3 \phi / 2 - 2c_2 \dot{\phi}^2 / 2 - 3c_3 \dot{\phi} \phi / M^3 + 3c_4 \dot{\phi}^3 [8H \phi + (3H^2 + 2H) \dot{\phi}] / (2M^6) - 3c_5 H \dot{\phi}^4 [5H \ddot{\phi} + 2(H^2 + H) \dddot{\phi}] / M^9.
\end{align*}
$$

The nonrelativistic fluid satisfies the continuity equation $\dot{\rho}_m + 3H \rho_m = 0$.

We shall consider the case in which the late-time cosmic acceleration is realized by the field kinetic terms, i.e. $c_1 = 0$. There is a de Sitter (dS) solution characterized by $H = H_{\text{dS}} = \text{constant}$ and $\dot{\phi} = \dot{\phi}_{\text{dS}} = \text{constant}$. From Eqs. (3) and (4) it then follows that

$$
\begin{align*}
c_2 x_{\text{dS}}^2 &= 6 + 9\alpha - 12\beta, \\
c_3 x_{\text{dS}}^3 &= 2 + 9\alpha - 9\beta,
\end{align*}
$$

where $x_{\text{dS}} = \frac{\dot{\phi}_{\text{dS}}}{H_{\text{dS}}}$ is the Hubble radius.
where $x_{dS} \equiv \phi_{dS}/(H_{dS} M_{Pl})$ and
\[ \alpha \equiv c_4 x^{4}_{dS}, \quad \beta \equiv c_5 x^{5}_{dS}. \] (9)

We normalize the mass $M$ to be $M^3 = M_{Pl} H_{dS}^2$. Since $H_{dS}$ is of the order of the present Hubble parameter ($H_0 \approx 10^{-40} M_{Pl}$), we have that $M \approx 10^{-60} M_{Pl}$.

In order to discuss the cosmological dynamics, it is convenient to introduce the following variables
\[ r_1 \equiv \frac{\dot{\phi}_{dS}}{\phi H}, \quad r_2 \equiv \frac{1}{r_1} \left( \frac{\dot{\phi}}{\phi_{dS}} \right)^4. \] (10)

At the dS point we have $r_1 = 1$ and $r_2 = 1$. The Friedmann equation (3) can be written as $\Omega_{DE} + \Omega_m = 1$, where $\Omega_m \equiv \rho_m/(3 M^2_{Pl} H^2)$ and
\[ \Omega_{DE} \equiv \frac{\rho_{DE}}{3 M^2_{Pl} H^2} = -\frac{1}{2} \left( 2 + 3 \alpha - 4 \beta \right) r_1 r_2 + \left( 2 + 9 \alpha - 9 \beta \right) r_1^2 r_2 - \frac{15}{2} \alpha r_1 r_2 + 7 \beta r_2. \] (11)

We also obtain the autonomous equations
\[ r_1' = \frac{1}{\Delta} (r_1 - 1) r_1 \left[ r_1 (r_1 (-3 \alpha + 4 \beta - 2) + 6 \alpha - 5 \beta) - 5 \beta \right] \times \left[ 18 + 3 r_2 (r_1 (-3 \alpha + 4 \beta - 2) + 2 r_2^2 (9 \alpha - 9 \beta + 1) - 15 r_1 \alpha + 14 \beta) \right], \] (12)
\[ r_2' = -\frac{1}{\Delta} (r_2 (6 r_2 (45 \alpha^2 - 4 (9 \alpha + 2) \beta + 36 \beta^2) + 7 (9 \alpha - 9 \beta + 2)) + r_1^4 (-66 (3 \alpha - 4 \beta + 2) - 3 r_2 (-2 (201 \alpha + 89) \beta + 15 \alpha_2 + 356 \beta^2) - 3 r_1 \alpha (123 r_2 \beta + 36) + 10 \beta (21 r_2 \beta - 3) + 3 r_1 r_2 (9 \alpha - 30 \alpha (4 \beta + 1) + 2 (2 - 9 \beta) + 3 r_1 r_2 (3 \alpha - 4 \beta + 2)^2 + 3 r_2^2 (9 \alpha - 9 \beta + 2) (3 \alpha - 4 \beta + 2)) \right]. \] (13)

where a prime represents a derivative with respect to $N = \ln a$, and
\[ \Delta \equiv 2 r_1^2 r_2 [72 \alpha^2 + 30 \alpha (1 - 5 \beta) + (2 - 9 \beta)^2] + 4 r_1^2 [9 r_2 (5 \alpha^2 + 9 \alpha \beta + (2 - 9 \beta) \beta) + 2 (9 \alpha - 9 \beta + 2)] + 4 r_1^2 [2 (-15 \alpha + 1) \beta + 3 \alpha (9 \alpha + 2) + 4 \beta^2] - 3 \alpha + 4 \beta - 2) - 24 r_1 \alpha (16 r_2 \beta + 3) + 10 \beta (21 r_2 \beta + 8). \] (14)

The Hubble parameter obeys the following equation
\[ \frac{H'}{H} = \frac{-5 r_1}{4 r_1} - \frac{r_2'}{4 r_2}. \] (15)

We define the dark energy equation of state $w_{DE}$ and the effective equation of state $w_{eff}$, as
\[ w_{DE} \equiv \frac{\rho_{DE}}{\rho_{DE}}, \quad w_{eff} \equiv -1 - \frac{2 H'}{3 H}. \] (16)

Using the continuity equation $\dot{\rho}_{DE} + 3 H (\rho_{DE} + p_{DE}) = 0$, we obtain the relation $w_{DE} = w_{eff} - \Omega'_{DE}/(3 \Omega_{DE})$.

There are three distinct fixed points: (A) $(r_1, r_2) = (0, 0)$, (B) $(r_1, r_2) = (1, 0)$, and (C) $(r_1, r_2) = (1, 1)$. As we see from the definition in Eq. (10) the point (C) corresponds to the dS solution, which is always classically stable [17]. The point (B) is a tracker solution found in Ref. [16], along which the field velocity evolves as $\dot{\phi} \propto 1/H$. The fixed point (B) is followed by the stable dS solution once $r_2$ grows to the order of 1. Depending on the initial conditions of $r_1$, the epoch at which the solutions approach the tracker is different.

In the following we summarize the background evolution in two regimes: (i) $r_1 \ll 1, r_2 \ll 1$ and (ii) $r_1 = 1$ [16, 17].

- (i) $r_1 \ll 1, r_2 \ll 1$

  This is the regime in which the term $L_5$ gives the dominant contribution in Eq. (11), i.e.
\[ \Omega_{DE} \approx 7 \beta r_2. \] (17)

Since $r_1' \approx 9 r_1/8$ and $r_2' \approx 3 r_2/8$ from Eqs. (12) and (13), the two variables $r_1$ and $r_2$ evolve as
\[ r_1 \propto a^{9/8}, \quad r_2 \propto a^{3/8}. \] (18)
During the matter era we have
\[ w_{\text{DE}} \simeq -1/8, \quad w_{\text{eff}} \simeq 0. \quad (19) \]

If \( \beta r_2 > 0 \), then the scalar ghosts do not appear [16, 17]. For the initial conditions with \( r_2 > 0 \) we require that
\[ \beta > 0. \quad (20) \]

The conditions for the avoidance of Laplacian instabilities are automatically satisfied [16, 17].

- (ii) \( r_1 = 1 \)

Along the tracker characterized by \( r_1 = 1 \), there is a simple relation
\[ \Omega_{\text{DE}} = r_2. \quad (21) \]

In the regime \( r_2 \ll 1 \) one has \( r'_2 \simeq 6r_2 \) from Eq. (13), so that the evolution of \( r_2 \) during the deep matter era is given by
\[ r_2 \propto a^6. \quad (22) \]

Along the tracker the evolution of the Hubble parameter can be analytically known as [40]
\[ \left( \frac{H(z)}{H_0} \right)^2 = \frac{1}{2} \Omega_{m0}(1 + z)^3 + \sqrt{1 - \Omega_{m0} + \frac{(1 + z)^6}{4} (\Omega_{m0})^2}, \quad (23) \]

where \( z = a_0/a - 1 \) is the redshift (\( a_0 \) is the scale factor today), and \( \Omega_{m0} \) is the density parameter of nonrelativistic matter today. Even in the presence of radiation and the cosmic curvature there exists an analytic form of \( H(z) \) [40].

Since \( \rho_{\text{DE}} = 3M^6/H^2 \) and \( p_{\text{DE}} = -3M^6 (2 + w_{\text{eff}})/H^2 \), it follows that
\[ w_{\text{DE}} = -2 - w_{\text{eff}} = -\frac{2}{r_2 + 1}, \quad w_{\text{eff}} = -\frac{2r_2}{r_2 + 1}. \quad (24) \]

In the deep matter era (\( r_2 \ll 1 \)) we have \( w_{\text{DE}} = -2 \) and \( w_{\text{eff}} = 0 \), whereas at the dS solution \( w_{\text{DE}} = w_{\text{eff}} = -1 \). The conditions for the avoidance of ghosts and Laplacian instabilities have been derived in Refs. [16, 17]. The allowed parameter space in the \((\alpha, \beta)\) plane is summarized in figure 1 of Ref. [16].

It should be pointed out that the tracker solution and the \( \mathcal{L}_5 \)-dominant solution can be distinguished also by means of the following physical quantity. When \( c_1 = 0 \) one has \( \partial L/\partial \phi = 0 \), where \( L \equiv \sqrt{-g} \mathcal{L} \) is the Lagrangian including the volume factor \( \sqrt{-g} \) in Eq. (1). Then the conjugate momentum to the field \( \phi \) is conserved, so that \( \partial L/\partial \dot{\phi} = \text{constant} \).

This constraint can be written as
\[ P_\phi \equiv \frac{r_2^{1/4} a^3 (1 - r_4)}{r_1^{1/4}} \left( 2 r_1^2 + 3a r_1^2 - 4\beta r_1^2 - 6\alpha r_1 + 5\beta r_1 + 5\beta \right) = \text{constant}. \quad (25) \]

On the tracker \( P_\phi \) exactly vanishes\(^1\), whereas for the \( \mathcal{L}_5 \)-dominant solution \( P_\phi \simeq 5\beta a^3 (r_2/r_1^{11})^{1/4} \neq 0 \). Although Eq. (25) is not independent of the others, we will use it later on in order to check the good convergence of numerical solutions.

### III. COSMOLOGICAL PERTURBATIONS

Let us consider scalar metric perturbations \( \Psi, \Phi, \) and \( \chi \) about the flat FLRW background [42]:
\[ ds^2 = -(1 + 2\Psi)dt^2 - 2\partial_i \chi dt dx^i + a^2(t)(1 + 2\Phi)\delta_{ij} dx^i dx^j, \quad (26) \]

\(^1\) The tracker can then be seen as the zero momentum solutions.
where we have chosen the spatial gauge such that the spatial metric is diagonal\(^2\). There is still a freedom to fix the temporal part \(\Xi_0\) of a vector associated with a scalar gauge transformation. Later on we will discuss this gauge degree of freedom in more detail.

The field \(\phi\) is decomposed into the background and inhomogeneous parts, as \(\phi(t,\bm{x}) = \bar{\phi}(t) + \delta\phi(t,\bm{x})\). In the following we omit the tilde for the background quantity. We shall use the action approach rather than taking the usual step of linearizing the equations of motion, as the former is more convenient from a computational point of view (indeed the scalar Lagrangian is quite compact compared to the tensorial equations of motion). Evidently the two approaches lead to equivalent equations of motion with the same set of solutions. For the perfect fluid, we cannot set \(w = 0\) in Eq. (11) identically from the beginning as its action would vanish. However, we can consider a fluid whose equation of state parameter \(w\) is different from zero, and only after we obtain the equations of motion for the perturbation variables, we will take the limit \(w \to 0\). Since we are interested in the scalar perturbations of a cold fluid (temperature \(T = 0\)) with a barotropic equation of state of the form \(p_m = \omega p_m\) (in the limit \(w \to 0\)), the action approach of linear perturbation theory for a perfect fluid introduced in Refs. [43] can be simplified as follows.

Let us define a 4-velocity of the perfect fluid, as \(u_\alpha = \mu^{-1} \partial_\alpha \ell\). This relation defines \(\ell\), which completely describes the scalar component of \(u_\alpha\) for the case under study. The normalization of the 4-velocity \((u_\alpha u^\alpha = -1)\) implies that \(\mu = \sqrt{-g^{\alpha\beta} \partial_\alpha \ell \partial_\beta \ell}\). Then at linear level we have \(\delta\mu = -\delta\ell - \mu \Psi\). Now the quantity \(\sqrt{-g} p_m(\mu, s)\) can be expanded at second order in the gravitational fields and in \(\delta\ell\) and \(\delta s\). However, since the fluid is cold \((T = 0)\), the first principle of thermodynamics, \(dp_m = \mu ds - nT ds\), imposes that \((\partial p_m / \partial s)_{\mu}, (\partial^2 p_m / \partial s^2)_{\mu}\), and \((\partial^2 p_m / \partial s \partial \mu)\) vanish\(^3\). In turn this implies that \(p_m\) depends on \(\mu\) alone, and we do not need to expand the action in terms of \(\delta s\), the entropy perturbation field\(^4\). Since the action for matter is a function of \(\mu\) alone, as \(p_m = p_m(\mu)\), and \(\delta\mu\) is a function of the perturbation variables \(\ell, \Psi\), the barotropic perfect fluid introduces only one new independent perturbed scalar field, \(\delta\ell\). Furthermore, since \(p_m = n\mu - p_m\), it follows that \(dp_m = \mu dn + nT ds = \mu dn = \mu \delta\mu / \mu\) at linear level. Using the field redefinition \(\delta\ell = -\mu v\), where \(v\) is a velocity potential for the perfect fluid, after some algebra, we find

\[
\dot{v} + 3H\dot{w}v = \Psi + \frac{w}{1 + w}\delta,
\]

where \(\delta \equiv \delta\rho_m / \rho_m\) is the density contrast.

In Fourier space the density contrast obeys the following equation of motion [14]

\[
\dot{\delta} = -(1 + w) \left( 3\Phi + \frac{k^2}{a^2} v - \frac{k^2}{a^2} \chi \right),
\]

where \(k\) is a comoving wavenumber. This equation follows from the first-order part of the continuity equation \(\nabla_\mu T^\mu_0 = 0\). In the following we derive other perturbation equations from the second-order action for perturbations. In Appendix A we will show how to obtain Eq. (28) from the action approach.

Let us consider nonrelativistic matter with \(w = 0\). We introduce the gauge-invariant matter perturbation \(\delta_m\), as [12]

\[
\delta_m \equiv \delta + 3Hv.
\]

Using Eqs. (28) and (27), it follows that

\[
\dot{\delta}_m + 2H\dot{\delta}_m + \frac{k^2}{a^2} (\Psi - \dot{\chi}) = 3(\dot{Q} + 2H\dot{Q}),
\]

where \(Q \equiv Hv - \Phi\).

Let us now derive the coupled equations for metric/field/matter perturbations. Expansion of the action [11] at second order gives

\[
[\sqrt{-g} L]^{(2)} \equiv L(\Psi, \Phi, \chi, \delta\phi, v).
\]

Equation (27) shows that \(\delta\) and \(\Psi\) are not independent fields. In the second-order action (31) we have chosen the latter field. If we vary the Lagrangian (31) with respect to \(\Psi\), then we find a term \(\rho_m(\Psi - \dot{v}) / w\) that leads to an

\(^2\) In the published PRD version there is an extra factor \(a(\ell)\) in front of the \(\partial_\ell \chi\) term. We corrected this typo.

\(^3\) This also implies that \(n = n(\mu)\). For example, \(\mu \propto n^w\) is enough to give \(p_m = w\rho_m\).

\(^4\) In the equations of motion approach, this result corresponds to the fact that, once \(p_m = w\rho_m\), no entropy perturbations appear in the dynamical equations.
apparent singularity for \( w \to 0 \). However, Eq. (27) allows to reduce this term to \(-\rho_m[\delta/(1 + w) + 3Hv]\). Taking the limit \( w \to 0 \) at the end, we obtain the equation of motion

\[
E_\Phi \equiv A_1 \ddot{\Phi} + A_2 \dot{\delta} \Phi - \rho_m \dot{v} + A_3 \frac{k^2}{a^2} \Phi + A_4 \Psi + A_5 \frac{k^2}{a^2} \chi + \left( \frac{1}{2} c_1 M^3 + A_6 \frac{k^2}{a^2} \right) \delta \phi - \rho_m \delta = 0, \tag{32}
\]

where the coefficients \( A_i \) are given in Appendix B. For the theories up to the Lagrangian \( \mathcal{L}_2 \) we have checked that, after substituting the relation \( \dot{v} = \Psi \) [which comes from Eq. (27)] and using the background Friedmann equation for the coefficient of \( \Psi \), Eq. (32) reduces to the usual 0-0 component of the perturbed Einstein equation obtained in the literature (see e.g. [45]). Variations of the second-order Lagrangian \( L \) with respect to \( \Phi, \chi \), and \( \delta \phi \) result in the following equations

\[
E_\Phi \equiv B_1 \ddot{\Phi} + B_2 \dot{\delta} \Phi + B_3 \dot{\Phi} + B_4 \delta \Phi + B_5 \dot{\Psi} + B_6 \frac{k^2}{a^2} \phi + \left( B_7 \frac{k^2}{a^2} + \frac{3}{2} c_1 M^3 \right) \delta \phi
\]

\[
+ \left( B_8 \frac{k^2}{a^2} + B_9 \right) \Psi + B_{10} \frac{k^2}{a^2} \chi + B_{11} \frac{k^2}{a^2} \chi + 3 \rho_m \dot{v} = 0, \tag{33}
\]

\[
E_\chi \equiv C_1 \dot{\Phi} + C_2 \dot{\delta} \phi + C_3 \Psi + C_4 \delta \phi + \rho_m \dot{v} = 0, \tag{34}
\]

\[
E_\delta \phi \equiv D_1 \ddot{\Phi} + D_2 \dot{\delta} \phi + D_3 \dot{\Phi} + D_4 \delta \phi + D_5 \dot{\Psi} + D_6 \frac{k^2}{a^2} \chi
\]

\[
+ \left( D_7 \frac{k^2}{a^2} + D_8 \right) \Phi + D_9 \frac{k^2}{a^2} \delta \phi + \left( D_{10} \frac{k^2}{a^2} + D_{11} \right) \Psi + D_{12} \frac{k^2}{a^2} \chi = 0, \tag{35}
\]

where the coefficients \( B_i, C_i, \) and \( D_i \) are given in Appendix B. \( E_\Phi \) corresponds to the spatial trace of the perturbed modified Einstein equations, \( E_\chi \) to the momentum constraint, and \( E_\delta \phi \) to the perturbed equation of motion for the Galileon field. Varying the Lagrangian \( L \) in terms of \( v \) gives rise to Eq. (27), i.e. \( \dot{v} = \Psi \) for \( w = 0 \).

Another constraint equation can be found by introducing the perturbation \( \gamma \) in the metric \( (20) \), as \( \delta g_{ij} = 2a^2 \partial_i \partial_j \gamma \). Its equation of motion is given by

\[
E_\gamma \equiv \frac{1}{3} \left( B_1 \ddot{\Phi} + B_2 \dot{\delta} \phi + B_3 \dot{\Phi} + B_4 \delta \phi + B_5 \dot{\Psi} + B_6 \Psi \right) + \frac{1}{2} c_1 M^3 \delta \phi + \rho_m \dot{v} = 0, \tag{36}
\]

which does not contain \( \gamma \) explicitly (as the quadratic terms in \( \gamma \) in the action can be integrated out). Evaluating \( E_\delta - 3E_\gamma \) leads to the following equation

\[
\dot{E}_\gamma \equiv B_6 \dot{\Phi} + B_7 \dot{\delta} \phi + B_8 \dot{\Psi} + B_{10} \chi + B_{11} \chi = 0. \tag{37}
\]

The same relation can be derived by using the Bianchi identities, see Appendix A.

In what follows we choose the longitudinal gauge with \( \chi = 0 \). This choice, together with imposing \( \gamma = 0 \), completely fixes the gauge. We also set \( c_1 = 0 \) to discuss the evolution of cosmological perturbations.

IV. QUASISTATIC APPROXIMATION ON SUBHORIZON SCALES

Let us consider the evolution of perturbations for the modes deep inside the Hubble radius. We derive the equations of matter perturbations and gravitational potentials under the quasistatic approximation on subhorizon scales \( (k \gg aH) \). This corresponds to the approximation under which the dominant contributions to the perturbation equations are those including \( k^2/a^2 \) and \( \delta \) \[45, 47\]. In the longitudinal gauge we obtain the following approximate equations from Eqs. (32), (37), and (35):

\[
\frac{k^2}{a^2} (A_3 \Phi + A_6 \delta \phi) \simeq \rho_m \delta, \tag{38}
\]

\[
B_9 \Phi + B_7 \delta \phi + B_8 \Psi = 0, \tag{39}
\]

\[
D_2 \Phi + D_5 \delta \phi + D_{10} \Psi \simeq 0. \tag{40}
\]

From Eqs. (39) and (40) one can express \( \Phi \) and \( \delta \phi \) in terms of \( \Psi \), i.e.

\[
\Phi \simeq \frac{A_3 D_9 - A_6 B_7}{B_7^2 - B_6 D_9} \Psi, \tag{41}
\]

\[
\delta \phi \simeq \frac{A_6 B_9 - A_5 B_7}{B_7^2 - B_6 D_9} \Psi. \tag{42}
\]
where we have used $B_6 = A_3$, $D_7 = B_7$, and $D_{10} = A_6$. Substituting Eqs. (11) and (12) into Eq. (38), it follows that

$$\frac{k^2}{a^2} \Psi \simeq -4\pi G_{\text{eff}} \rho_m \delta ,$$  

(43)

where

$$G_{\text{eff}} = \frac{2 M_p^2 (B_7^2 - B_6 D_9)}{2 A_3 A_6 B_7 - A_3^2 D_9 - A_6^2 B_6} G .$$  

(44)

Since $|\dot{\delta}|$ is at most of the order of $|H \delta|$ in Eq. (28), one has $(|k^2/a^2|)^{\frac{1}{2}} \lesssim |H \delta|$. This means that $|H v / \delta| \lesssim (aH/k)^2 \ll 1$ for subhorizon modes, which leads to $\delta_m \simeq \delta$ in Eq. (29). Since the r.h.s. of Eq. (30) can be neglected relative to the l.h.s., we obtain the equation for the gauge-invariant matter perturbation for the modes deep inside the Hubble radius:

$$\ddot{\delta}_m + 2 H \dot{\delta}_m - 4 \pi G_{\text{eff}} \rho_m \delta_m \simeq 0 ,$$  

(45)

where we have used the Poisson equation (43).

From Eqs. (42) and (43) the field perturbation is given by

$$\delta \phi \simeq \frac{3 M_p^2 (A_3 B_7 - A_6 B_6)}{2 A_3 A_6 B_7 - A_3^2 D_9 - A_6^2 B_6} \left( \frac{aH}{k} \right)^2 \Omega_m \delta .$$  

(46)

We introduce the following quantity to describe the difference between the two gravitational potentials:

$$\eta \equiv - \frac{\Phi}{\Psi} \simeq \frac{A_3 D_9 - A_6 B_7}{B_6 D_9 - B_7^2} ,$$  

(47)

where we have used Eq. (11) in the last approximate equality. We also define the effective gravitational potential

$$\Phi_{\text{eff}} \equiv (\Psi - \Phi) / 2 ,$$  

(48)

which is related with the deviation of the light rays in CMB and weak lensing observations [41]. From the Poisson equation (43) it follows that

$$\frac{k^2}{a^2} \Phi_{\text{eff}} \simeq -4\pi G_{\text{eff}} \frac{1 + \eta}{2} \rho_m \delta .$$  

(49)

Using the density parameter $\Omega_m = 8\pi G \rho_m / (3H^2)$ and the relation $\delta_m \simeq \delta$, we have

$$\Phi_{\text{eff}} \simeq - \frac{3}{2} \frac{G_{\text{eff}}}{G} \frac{1 + \eta}{2} \Omega_m \delta_m \left( \frac{aH}{k} \right)^2 .$$  

(50)

The matter perturbation equation (45) can be written as

$$\delta_m'' + \left( 2 + \frac{H'}{H} \right) \delta_m' - \frac{3}{2} \frac{G_{\text{eff}}}{G} \Omega_m \delta_m \simeq 0 ,$$  

(51)

In the limit that $\dot{\phi} \to 0$ and $\ddot{\phi} \to 0$, the effective gravitational coupling $G_{\text{eff}}$ reduces to $G$. Hence, in the early cosmological epoch, the General Relativistic behavior is recovered. If $G_{\text{eff}} \simeq G$, then the evolution of matter perturbations during the deep matter era ($H'/H \simeq -3/2$ and $\Omega_m \simeq 1$) is given by $\delta_m \propto a \propto t^{2/3}$.

As the field velocity grows in time, $G_{\text{eff}}$ is subject to change. This leads to the modified growth rate of matter perturbations compared to the $\Lambda$-cold dark matter ($\Lambda$CDM) model. Unlike $f(R)$ gravity [47] and Brans-Dicke theory [48], the effective gravitational coupling is independent of the wave number $k$. The quantity $\eta$ defined in Eq. (47) reduces to 1 for $\dot{\phi} \to 0$ and $\ddot{\phi} \to 0$, but it deviates from 1 with the growth of $\dot{\phi}$ and $\ddot{\phi}$. In three different regimes characterized by (i) $r_1 \ll 1$, $r_2 \ll 1$, (ii) $r_1 = 1$, $r_2 \ll 1$, and (iii) $r_1 = 1$, $r_2 = 1$, one can estimate $G_{\text{eff}}$ and $\eta$ as follows.

- (i) $r_1 \ll 1$, $r_2 \ll 1$
In this section we present numerical results for the evolution of perturbations without employing the quasistatic approximation on subhorizon scales. The accuracy of the quasistatic approximation will be confirmed for the modes \( k \gg aH \).

Among the six equations \((32) - (37)\), three of them are independent. For the numerical purpose we solve Eqs. \((32)\) and \((37)\) together with Eqs. \((27)\) and \((28)\). We have also confirmed that \( P_\phi \) defined in Eq. \((26)\) remains constant up to the accuracy of \(10^{-8}\) during the whole evolution. It is convenient to introduce the following dimensionless variables

\[
V \equiv H\nu, \quad \delta \phi \equiv \delta \phi / (x_{dS} M_{pl}),
\]

with \( \bar{A}_1 \equiv A_1 / (H M_{pl}^2), \bar{A}_2 \equiv x_{dS} A_2 / (H M_{pl}), \bar{A}_3 \equiv A_3 / M_{pl}^2, \bar{A}_4 \equiv A_4 / (H^2 M_{pl}^2), \bar{A}_6 \equiv x_{dS} A_6 / M_{pl}, \bar{B}_6 \equiv B_6 / M_{pl}, \bar{B}_7 \equiv x_{dS} B_7 / M_{pl}, \) and \( \bar{C}_4 \equiv x_{dS} C_4 / (H M_{pl}). \) In the longitudinal gauge we obtain the following equations from

\[
\frac{G_{\text{eff}}}{G} = 1 + \left( \frac{255}{8} \beta + \frac{211}{16} \alpha \right) r_2 + \mathcal{O}(r_2^2),
\]

\[
\eta = 1 + \left( \frac{129}{8} \beta + \frac{589}{16} \alpha \right) r_2 + \mathcal{O}(r_2^2).
\]

In this section we present numerical results for the evolution of perturbations without employing the quasistatic approximation on subhorizon scales. The accuracy of the quasistatic approximation will be confirmed for the modes \( k \gg aH \).

Among the six equations \((32) - (37)\), three of them are independent. For the numerical purpose we solve Eqs. \((32)\) and \((37)\) together with Eqs. \((27)\) and \((28)\). We have also confirmed that \( P_\phi \) defined in Eq. \((26)\) remains constant up to the accuracy of \(10^{-8}\) during the whole evolution. It is convenient to introduce the following dimensionless variables

\[
V \equiv H\nu, \quad \delta \phi \equiv \delta \phi / (x_{dS} M_{pl}),
\]

with \( \bar{A}_1 \equiv A_1 / (H M_{pl}^2), \bar{A}_2 \equiv x_{dS} A_2 / (H M_{pl}), \bar{A}_3 \equiv A_3 / M_{pl}^2, \bar{A}_4 \equiv A_4 / (H^2 M_{pl}^2), \bar{A}_6 \equiv x_{dS} A_6 / M_{pl}, \bar{B}_6 \equiv B_6 / M_{pl}, \bar{B}_7 \equiv x_{dS} B_7 / M_{pl}, \) and \( \bar{C}_4 \equiv x_{dS} C_4 / (H M_{pl}). \) In the longitudinal gauge we obtain the following equations from

\[
\frac{G_{\text{eff}}}{G} = 1 + \left( \frac{255}{8} \beta + \frac{211}{16} \alpha \right) r_2 + \mathcal{O}(r_2^2),
\]

\[
\eta = 1 + \left( \frac{129}{8} \beta + \frac{589}{16} \alpha \right) r_2 + \mathcal{O}(r_2^2).
\]
\( \alpha \) can be expressed by using the variables \( V \), this gives two constraints on the variables \( \Phi \), which are determined accordingly. For the modes deep inside the Hubble radius, Eq. (46) provides a relation between \( \delta \phi \) and \( V \). We choose the initial condition \( \delta \phi = 0 \). For large initial values of \( \delta \phi \), the field perturbation tends to oscillate for small-scales modes (associated with large wave numbers \( k \)). This situation is similar to what happens in the generalized Galileon model [20].

We identify the present epoch (the redshift \( z = 0 \)) to be \( \Omega_{DE} = 0.72 \). In order to find the evolution of the quantity

\[
\Psi = -(\ddot{B} \Phi + \dot{B} \dot{\delta \phi})/A,
\]

\[
\Phi' = [(3 \dot{A} \dot{A} \dot{B} + \dot{A} \dot{A} \dot{B} + 3 \dot{A} \dot{A} \dot{B} - 9 \dot{A} \dot{B} \delta) A]/(-9 A \dot{B} \delta) \Phi
\]

\[
+ (3 \dot{A} \dot{A} \dot{B} + 3 \dot{A} \dot{A} \dot{B} + \dot{A} \dot{A} \dot{B} - 9 \dot{A} \dot{B} \delta) A /(-9 A \dot{B} \delta) \Phi
\]

\[
\times [3 \dot{A} \dot{A} \dot{B} - \dot{A} \dot{A} \dot{B}]^{-1},
\]

\[
\delta \phi' = -(\dot{B} \dot{B} + 3 \dot{A} \dot{A} \dot{B} - 3 \dot{A} \dot{A} \dot{B}) /(-9 \dot{B} \delta) \Phi
\]

\[
+ (\dot{B} \dot{B} + 3 \dot{A} \dot{A} \dot{B} + \dot{A} \dot{A} \dot{B} - 9 \dot{A} \dot{B} \delta) A /(-9 \dot{B} \delta) \Phi
\]

\[
\times [3 \dot{A} \dot{A} \dot{B} - \dot{A} \dot{A} \dot{B}]^{-1},
\]

\[
\delta' = -3 \Phi' - k^2 /(-9 A \dot{B} \delta) \Phi
\]

\[
V' = (H' / H) V + \Psi,
\]

where we have used \( \dot{B} = \dot{A}, \dot{C} = \dot{A}, \dot{C} = \dot{A}, \) and \( C = -A / 3 \). The time-dependent coefficients \( A, B, \) etc. can be expressed by using the variables \( \alpha, \beta, r_1, \) and \( r_2 \). Solving the perturbation equations for the model parameters \( \alpha = 1.37 \) and \( \beta = 0.44 \) with two different initial conditions: (A) \( r_1 = 0.03, r_2 = 0.003, \) and (B) \( r_1 = 0.999, r_2 = 7.0 \times 10^{-11} \). The case (B) corresponds to the tracker solution, whereas in the case (A) the solution approaches the tracker around today. The present epoch (\( z = 0 \)) is shown as a dotted line (we also draw the dotted line in other figures).
Figure 2: Evolution of the perturbations for $\alpha = 1.37$ and $\beta = 0.44$ with the background initial conditions $r_1 = 0.03$ and $r_2 = 0.003$ (corresponding to the case (A) of Fig. 1). (Left) $\delta_m/a$ versus $z$ for the wave numbers (a) $k = 300a_0H_0$, (b) $k = 30a_0H_0$, and (c) $k = 5a_0H_0$. (Right) $\Phi_{\text{eff}}$ versus $z$ for the wave numbers (a) $k = 300a_0H_0$, (b) $k = 10a_0H_0$, and (c) $k = 5a_0H_0$. Note that $\delta_m/a$ and $\Phi_{\text{eff}}$ are divided by their initial amplitudes $\delta_m(t_i)/a(t_i)$ and $\Phi_{\text{eff}}(t_i)$, respectively, so that their initial values are normalized to be 1. The bold dotted lines show the results obtained under the quasistatic approximation on subhorizon scales. The choice of initial conditions for perturbations is explained in the text.

$k/(aH)$, we also integrate the following equation

$$b' = b'(1 + H'/H'),$$

(64)

where $b \equiv aH$. The scales relevant to the linear regime of the galaxy power spectrum are $30 \lesssim k/(a_0H_0) \lesssim 600$, where the subscript “0” represents present values. Note that the above upper limit corresponds to $k = 0.2\,h\,\text{Mpc}^{-1}$, where $h = 0.72 \pm 0.08$ [49]. For the scales $k/(a_0H_0) \gtrsim 600$ the nonlinear effect becomes crucially important. Meanwhile, the wave numbers relevant to the ISW effect in CMB anisotropies correspond to the large-scale modes with $k/(a_0H_0) = O(1)$.

In Ref. [40] two of the present authors placed observational constraints on the Galileon model from the background expansion history of the Universe. The combined data analysis of the type Ia supernovae (Constitution and Union2 sets), the CMB shift parameters (WMAP7), and the baryon acoustic oscillations (BAO) show that the tracker solution described by Eq. (23) is not favored, but the solutions that approach the tracker at late times can be compatible with the background observational constraints. As illustrated in Fig. 1 the equation of state $w_{\text{DE}}$ for the tracker [case (B)] evolves from $-2$ (deep matter era) to $-1$ (dS epoch). The solution (A) in Fig. 1 starts to evolve from the value $w_{\text{DE}} = -1/8$ and then it enters the tracking regime around the present epoch. In the flat FLRW background the best-fit model parameters are $\alpha = 1.411 \pm 0.056$, $\beta = 0.422 \pm 0.022$ (Constitution + CMB + BAO, 68% C.L.), and $\alpha = 1.404 \pm 0.057$, $\beta = 0.419 \pm 0.023$ (Union2 + CMB + BAO, 68% C.L.).

A. Case of late-time tracking solutions

Let us consider the evolution of perturbations for the late-time tracking solutions. In Fig. 2 we plot $\delta_m/a$ and $\Phi_{\text{eff}}$ versus the redshift $z$ with the model parameters and initial conditions corresponding to the case (A) of Fig. 1. For the mode $k = 300a_0H_0$ we find that the full numerical result shows excellent agreement with that obtained under the quasistatic approximation on subhorizon scales. The difference starts to appear for the modes $k/(a_0H_0) < O(10)$. The left panel of Fig. 2 shows that, on larger scales, the growth of $\delta_m/a$ tends to be less significant. For the modes $k \gg a_0H_0$ the matter perturbation evolves faster than $a$ during the matter era (i.e. faster than in the case of GR, $\delta_m \propto a$). The growth of $\delta_m/a$ turns into decrease after the Universe enters the epoch of cosmic acceleration.
In Fig. 3 we show the evolution of the growth index $\gamma$ defined by

$$\frac{\delta'_m}{\delta_m} = (\Omega_m)^{\gamma}. \quad \text{(65)}$$

The case (A) in Fig. 3 corresponds to the same model parameters and initial conditions as those given in the numerical simulations of Fig. 2. Unlike the $\Lambda$CDM model in which $\gamma$ is nearly constant ($\simeq 0.55$) in the low-redshift regime $0 < z < 1$, the variation of $\gamma$ is significant for the solutions that approach the tracker at late times. Moreover, the growth index today for the mode $k = 300a_0H_0$ is $\gamma_0 = 0.35$, which is quite different from that in the $\Lambda$CDM. For the wave lengths relevant to large-scale structures we find that the growth index today exhibits almost no dispersion with respect to $k$. This property is different from viable $f(R)$ dark energy models in which $\gamma_0$ can be dispersed [52]. If we choose smaller initial values of $r_1$ (i.e. the later tracking), we find that $\gamma_0$ tends to be smaller, e.g. $\gamma_0 = 0.23$ for the initial conditions $r_1 = 0.01$, $r_2 = 0.003$ with the model parameters $\alpha = 1.37$, $\beta = 0.44$.

The right panel of Fig. 2 shows that, unlike the $\Lambda$CDM model, the effective gravitational potential $\Phi_{\text{eff}}$ changes in time even during the matter era for the modes $k \gg aH$. This can be understood as follows. For the initial conditions corresponding to the late-time tracking solutions the effective gravitational coupling $G_{\text{eff}}$ and the anisotropic parameter $\eta$ are given by Eqs. (52) and (53), respectively, before reaching the tracker. Since $G_{\text{eff}}/G \simeq 1 + 255\beta r_2^2/8 > 1$ and $\eta \simeq 1 + 129\beta r_2 > 1$ in this regime, we have the larger growth rates of $\Phi_{\text{eff}}$ and $\delta_m$ relative to those in GR. In particular the term $(G_{\text{eff}}/G)(1 + \eta)/2$ in Eq. (50) is larger than 1, which leads to the additional enhancement of $\Phi_{\text{eff}}$ to the growth coming from $\delta_m$. Note that in $f(R)$ gravity [17] and in Brans-Dicke theory [18] one has $(G_{\text{eff}}/G)(1 + \eta)/2 = 1$, so that the evolution of $\delta_m$ is directly related with the variation of $\Phi_{\text{eff}}$. In Galileon gravity the unusual behavior of the anisotropic parameter $\eta$ leads to the nontrivial evolution of perturbations. For the model parameters $\alpha = 1.37$ and $\beta = 0.44$, Eq. (50) gives $G_{\text{eff}} \simeq 0.68G$ at the dS fixed point. As we see in Fig. 2 $\Phi_{\text{eff}}$ begins to decrease at some point after the matter era.

For the large-scale modes relevant to the ISW effect in CMB anisotropies, i.e. $k/(a_0H_0) \lesssim 10$, the effective gravitational potential is nearly constant in the early matter-dominated epoch, see the cases (b) and (c) in the right panel of Fig. 2. However, $\Phi_{\text{eff}}$ exhibits temporal growth during the transition from the matter era to the epoch of cosmic acceleration. Note that in the $\Lambda$CDM model $\Phi_{\text{eff}}$ decays without the temporal growth after the matter era. The characteristic variation of $\Phi_{\text{eff}}$ in the Galileon model should leave observational signatures in CMB anisotropies as the ISW effect.

---

5 For the dark energy models with constant $w_{\text{DE}}$ and $\gamma$, the current observations still allow the large parameter space of $\gamma$ ranging from 0.2 to 0.6. [53].
Figure 4: Evolution of (i) $\delta_m/a$ and (ii) $\Phi_{\text{eff}}$ versus $z$ for $\alpha = 1.37$ and $\beta = 0.44$ with the initial conditions $r_1 = 0.999$ and $r_2 = 7.0 \times 10^{-11}$ [corresponding to the case (B) of Fig. 1]. Both $\delta_m/a$ and $\Phi_{\text{eff}}$ are divided by their initial amplitudes. In this case the background cosmological solution is on the tracker from the onset of integration. The solid line shows the evolution of perturbations for the mode $k = 5a_0H_0$, whereas the bold dotted line and bold dashed line represent the result derived under the quasistatic approximation on subhorizon scales.

The above numerical results correspond to the fixed values of $\alpha$ and $\beta$ ($\alpha = 1.37$, $\beta = 0.44$). If we use the bounds $\alpha = 1.404 \pm 0.057$, $\beta = 0.419 \pm 0.023$ constrained by Union2+CMB+BAO data sets, the effective gravitational coupling at the dS point is restricted in the range $0.24 G < G_{\text{eff}} < 0.71 G$. The bounds coming from Constitution+CMB+BAO data give the similar constraint, i.e. $0.24 G < G_{\text{eff}} < 0.71 G$. For the model parameters close to the upper limit $\alpha = 2\beta + 2/3$ of the allowed parameter space (i.e. $G_{\text{eff}}$ is close to $0.5G$ at the dS point), the parameter $\eta$ tends to show a divergence during the transition from the matter era to the dS epoch. If $G_{\text{eff}}$ is larger than $0.66G$, we find that such divergent behavior can be typically avoided.

For the parameters $\alpha$ and $\beta$ constrained observationally, the values of $\gamma_0$ are usually less than 0.4 for the late-time tracking with the minimum values of $w_{\text{DE}}$ larger than $-1.3$. In addition the later tracking leads to smaller values of $\gamma_0$ with larger variations of $\gamma$. This property of the Galileon model can be clearly distinguished from the $\Lambda$CDM model.

B. Case of early-time tracking solutions

If the solutions are already close to the tracker in the early matter-dominated epoch, the evolution of perturbations is different from that discussed above. For the tracker one has $r_2 \propto a^6$ during the matter dominance, which is much faster than the evolution $r_2 \propto a^{3/8}$ in the regime $r_1 \ll 1$ and $r_2 \ll 1$. This means that $r_2$ is very much smaller than 1 for the redshift $z \gtrsim 1$. Then the second terms on the r.h.s. of Eqs. (54) and (55) are suppressed relative to the first terms until recently. In Fig. 4 we plot the variation of $\delta_m/a$ and $\Phi_{\text{eff}}$ for $\alpha = 1.37$ and $\beta = 0.44$ with the background initial conditions corresponding to the case (B) in Fig. 1. The solid line shows the evolution of perturbations for the mode $k = 5a_0H_0$, whereas the bold dotted line and bold dashed line represent the result derived under the quasistatic approximation on subhorizon scales. In this case the evolution of the large-scale mode with $k = 5a_0H_0$ is similar to that for the modes deep inside the Hubble radius.

Figure 4 shows that the growth of matter perturbations in the deep matter era is almost identical to that in the $\Lambda$CDM model. In the regime $r_1 \simeq 1$ and $r_2 \ll 1$ one has $G_{\text{eff}}/G \simeq 1 + 3.2r_2$ and $\eta \simeq 1 - 3.7r_2$, both of which are very close to 1. Recall that at the dS point $G_{\text{eff}}/G \simeq 0.68$ and $\eta = 1$. Since $\eta$ is very close to 1 and $G_{\text{eff}}$ is different from $G$ only around the dS solution, the evolution of perturbations is milder than that corresponding to the late-time tracking solutions. The case (B) of Fig. 4 shows $\gamma$ versus $z$ for the mode $k = 300a_0H_0$ with the initial condition corresponding to the tracker solution. In this case the growth index today is found to be $\gamma_0 \simeq 0.47$ with the variation
of γ in the low-redshift regime. In Fig. 4 we also find the small temporal growth of Φ eff from the end of the matter era to the epoch of cosmic acceleration. This can also give rise to a nonnegligible contribution to the ISW effect in CMB anisotropies. We recall, however, that the tracker solution is not favored at the background level by the joint analysis of observational data.

C. Case of α = β = 0

Let us finally consider the model in which only the terms up to \( \mathcal{L}_3 \) are present, i.e. \( \alpha = \beta = 0 \). Although such a model is disfavored observationally, it is of interest to study what happens for the evolution of perturbations due to the peculiar divergence of \( G_{\text{eff}} \) at the dS point (which occurs along the line \( \alpha = 2\beta \)).

First of all we have numerically found that the late-time tracking behavior as in the case (A) of Fig. 1 is not easy to be realized even by choosing many different initial conditions. This is the main reason why the combined data analyses at the background level do not favor such model parameters. For \( \alpha = \beta = 0 \) one has \( \eta = 1 \) independent of the values of \( r_1 \) and \( r_2 \), whereas \( G_{\text{eff}} \simeq G \) for \( r_1 \ll 1, r_2 \ll 1 \) and \( G_{\text{eff}} \simeq 1 + r_2/4 \) for \( r_1 = 1, r_2 \ll 1 \).

In Fig. 5 we plot the variation of \( \delta_m/a \) and \( \Phi_{\text{eff}} \) with the initial conditions \( r_1 = 0.05 \) and \( r_2 = 0.001 \) for two different wave numbers: \( k = 300a_0H_0 \) and \( k = 5a_0H_0 \). In this simulation the solution reaches the tracker region \( (r_1 \simeq 1) \) around the redshift \( z = 5 \), e.g. \( r_1 = 0.99 \) and \( r_2 = 4.14 \times 10^{-4} \) at \( z = 5.34 \). Hence the evolution of perturbations for \( z \gtrsim 5 \) is similar to that in the ΛCDM model. The effective gravitational coupling \( G_{\text{eff}} \) increases with the growth of \( r_2 \) for \( z \lesssim 5 \). In this case the numerical value of \( G_{\text{eff}} \) today is \( G_{\text{eff}} \simeq 1.94G \) with \( r_2 \simeq 0.72 \). For the mode \( k = 300a_0H_0 \) the growth index today is found to be \( \gamma_0 \simeq 0.43 \), which is smaller than the value in the ΛCDM model.

In Fig. 5 the effective gravitational potential for the mode \( k = 300a_0H_0 \) grows around the present epoch in spite of the decrease of \( \delta_m/a \). This can be understood by the fact that the term \( (G_{\text{eff}}/G)(1 + \eta)^2/2 \) at \( \alpha = \beta = 0 \) continues to grow toward the dS solution. While the decrease of the density parameter \( \Omega_m \) overwhelms the increase of \( G_{\text{eff}}/G \) in Eq. (51) for matter perturbations, the presence of the additional term \( (aH/k)^2 \) in Eq. (50) stimulates the growth of \( \Phi_{\text{eff}} \) around today. Numerically we find that the growth of \( \Phi_{\text{eff}} \) eventually turns into the decrease in future as \( \delta_m \) decays sufficiently (which is not shown in Fig. 4). For \( k = 5a_0H_0 \) the growth of \( \Phi_{\text{eff}} \) around today is milder relative to the modes deep inside the Hubble radius.

The anticorrelation between \( \delta_m/a \) and \( \Phi_{\text{eff}} \) seen in Fig. 5 is similar to the one found in the generalized Galileon model [21]. This anticorrelation mainly comes from the fact that \( G_{\text{eff}}/G \) continues to grow toward the dS point and that the parameter \( \eta \) does not become smaller than 1 to compensate the growth of \( G_{\text{eff}}/G \) (unlike \( f(R) \) gravity and Brans-Dicke theory). In the numerical simulations of Fig. 6 the effective gravitational coupling is larger than \( G \) in
the regime \( r_1 \ll 1 \) and \( r_2 \ll 1 \), but it finally approaches the asymptotic value \( G_{\text{eff}} \approx 0.68G \). In this case both \( \delta_m/a \) and \( \Phi_{\text{eff}} \) start to decay by today, whose property is different from that in the case \( \alpha = \beta = 0 \). Since the observational constraints on \( \alpha \) and \( \beta \) do not allow the region close to the line \( \alpha = 2\beta \), the anticorrelation between \( \delta_m/a \) and \( \Phi_{\text{eff}} \) does not typically occur for the viable model parameters.

VI. CONCLUSIONS

We have studied the dynamics of cosmological perturbations in the Galileon model whose Lagrangian satisfies the Galileon symmetry \( \partial_\mu \phi \rightarrow \partial_\mu \phi + r_\mu \) in the flat space-time. In this theory there exist stable dS solutions with \( \phi = \text{constant} \). In the deep matter era the General Relativistic behavior can be recovered because of a small field velocity, but the Universe finally enters the epoch of cosmic acceleration after the growth of \( \phi \).

Before reaching the dS attractor, the solutions approach a tracker characterized by \( r_1 = 1 \) (i.e. the evolution \( \dot{\phi} \propto H^{-1} \)). The tracking epoch depends on the initial conditions of the background cosmological variables. The combined data analysis based on the background expansion history of the Universe (SN Ia+CMB shift parameters+BAO) favor the late-time tracking around today. This corresponds to the initial conditions \( r_1 \ll 1 \) and \( r_2 \ll 1 \) in the deep matter era, so that \( r_1 \) approaches 1 in the low-redshift regime \( (z \lesssim 1) \).

The study about the evolution of cosmological perturbations can allow us to distinguish the Galileon model from the \( \Lambda \text{CDM} \) model further. In the presence of a nonrelativistic perfect fluid, we have derived full perturbation equations for the model described by the action (1). In spite of their complexities it is possible to obtain simpler equations for the matter perturbation \( \delta_m \) and the effective gravitational potential \( \Phi_{\text{eff}} \) under a quasistatic approximation on subhorizon scales.

The two important quantities associated with the growth of \( \delta_m \) and \( \Phi_{\text{eff}} \) are the effective gravitational coupling \( G_{\text{eff}} \) and the anisotropic parameter \( \eta = -\Phi/\Psi \). In three distinct regimes we have approximately derived the expressions of \( G_{\text{eff}} \) and \( \eta \), see Eqs. (52)–(57). For the initial conditions that lead to the late-time tracking behavior, the solutions start from the regime \( r_1 \ll 1 \), \( r_2 \ll 1 \) with positive \( \beta \) (which is required to avoid ghosts). In this regime Eqs. (52) and (55) show that \( G_{\text{eff}}/G \approx 1 + 255\beta r_2/8 > 1 \) and \( \eta \approx 1 + 129\beta r_2/8 > 1 \). This gives rise to the larger growth rates of \( \delta_m \) and \( \Phi_{\text{eff}} \) relative to those in the \( \Lambda \text{CDM} \) model.

In \( f(R) \) gravity and Brans-Dicke theory the anisotropic parameter \( \eta \) is less than 1, so that the combination \( (G_{\text{eff}}/G)(1+\eta)/2 \) remains to be 1. In the Galileon model the fact that \( \eta > 1 \) in the regime \( r_1 \ll 1 \), \( r_2 \ll 1 \) leads to the further growth of \( \Phi_{\text{eff}} \) for subhorizon modes. At the dS fixed point we have that \( G_{\text{eff}}/G = 1/\beta(\alpha - 2\beta) \) and \( \eta = 1 \). For the parameters of \( \alpha \) and \( \beta \) observationally constrained at the background level [10], the effective gravitational coupling \( G_{\text{eff}} \) is smaller than 0.72\( G \). Then the perturbations \( \delta_m/a \) and \( \Phi_{\text{eff}} \) turn into decrease around today, as we see in the numerical simulation of Fig. 2.

For the solutions that approach the tracker at the early epoch of the matter era, \( G_{\text{eff}} \) and \( \eta \) are approximately given by Eqs. (54) and (55), respectively, in the regime \( r_1 = 1 \), \( r_2 \ll 1 \). Since the evolution of \( r_2 \) in the tracking regime is very fast \( (r_2 \propto a^\gamma) \), the correction term \( \beta r_2 \) to \( G_{\text{eff}} \) and \( \eta \) becomes important around the present epoch in which \( r_2 \) grows to the order of 1. Hence the deviation from the \( \Lambda \text{CDM} \) model for the evolution of \( \delta_m \) and \( \Phi_{\text{eff}} \) appears only at late times, as we see in Fig. 1. The early tracking behavior is however disfavored from joint observational constraints at the background level.

For the late-time tracking solutions we have found that the growth index \( \gamma \) of matter perturbations rapidly changes in the low-redshift regime [as in the case (A) of Fig. 3]. The values of \( \gamma \) today on the scales relevant to large-scale structures are typically smaller than 0.4 for the model parameters constrained by the observations at the background level. As the tracking occurs at a later epoch, the present values of \( \gamma \) tend to be smaller. On large scales relevant to the ISW effect in CMB anisotropies the effective gravitational potential \( \Phi_{\text{eff}} \) exhibits a temporal growth around the present epoch. These properties can potentially restrict the allowed region constrained by the background cosmic expansion history further. It will be of interest to constrain the Galileon model from the combined data analysis of large-scale structures, CMB, and weak lensing.

ACKNOWLEDGEMENTS

T. also thanks financial support for the Grant-in-Aid for Scientific Research on Innovative Areas (No. 21111006). S. T. is grateful to Bin Wang for warm hospitality during his stay in Shanghai Jiao Tong University.
Appendix A: Bianchi identities

We confirm the consistency of perturbation equations by using the Bianchi identities. We write the action \((1)\) in the form
\[
S = \int \! \! d^4x \sqrt{-g} \mathcal{L},
\]
where \(\mathcal{L}\) is the total Lagrangian. Variation of the action \((1)\) with respect to \(g_{\alpha\beta}\) gives
\[
\delta S = \int \! \! d^4x \sqrt{-g} \Sigma^{\alpha\beta} \delta g_{\alpha\beta}.
\]
Then the Bianchi identities lead to
\[
\nabla_\beta \Sigma^{\alpha\beta} = \partial_\beta \Sigma^{\alpha\beta} + \Gamma^\alpha_{\lambda\beta} \Sigma^{\lambda\beta} + \Gamma^\beta_{\lambda\beta} \Sigma^{\alpha\lambda} = 0,
\]
where \(\Gamma^\alpha_{\lambda\beta}\) is the Christoffel symbol.

We perturb Eq. \((A3)\) at first order. Then we find
\[
\partial_\beta \delta \Sigma^{\alpha\beta} + \Gamma^\alpha_{\lambda\beta} \delta \Sigma^{\lambda\beta} + \Gamma^\beta_{\lambda\beta} \delta \Sigma^{\alpha\lambda} = 0,
\]
where we have used the fact that the background equation satisfies \(\Sigma^{\alpha\beta} = 0\). For the case \(\alpha = 0\) we have
\[
\partial_0 \delta \Sigma^{00} + \partial_0 \delta \Sigma^{0i} + \Gamma^0_{0\beta} \delta \Sigma^{\lambda\beta} + \Gamma^0_{\beta\beta} \delta \Sigma^{00} + \Gamma^0_{i\beta} \delta \Sigma^{0i} = 0.
\]
Using the relations \(\Gamma^0_{00} = 0, \Gamma^0_{0i} = 0, \Gamma^0_{ij} = a^2 H \delta_{ij}, \Gamma^i_{00} = 0, \Gamma^i_{ij} = H \delta_{ij}, \Gamma^i_{jk} = 0, \) Eq. \((A5)\) reduces to
\[
\partial_0 \delta \Sigma^{00} + \partial_0 \delta \Sigma^{0i} + a^2 H \sum_i \delta \Sigma^{ii} + 3H \delta \Sigma^{00} = 0.
\]

In our Galileon model the condition \((A6)\) leads to the following relation
\[
E_1 = \dot{E}_\psi + 3H E_\psi - H E_\Phi - \frac{k^2}{a^2} E_\chi = 0,
\]
where \(E_\psi\) corresponds to Eq. \((B2)\), \(E_\Phi\) to Eq. \((B3)\), and \(E_\chi\) to Eq. \((B4)\). Combining Eq. \((B5)\) with Eq. \((A7)\) and inserting the background equations of motion, we find
\[
E_1 - \dot{\phi} E_\delta \phi = \rho_m \left( \frac{k^2}{a^2} \chi - 3 \dot{\phi} - \frac{k^2}{a^2} v - \dot{\delta} \right) = 0,
\]
which matches with Eq. \((B8)\) for \(w = 0\).

Equation \((B7)\) can be also derived from the spatial part of the Bianchi identities. It follows that
\[
\dot{E}_\gamma + 3H E_\chi - \frac{1}{3} E_\Phi = \frac{1}{3} \frac{k^2}{a^2} \dot{E}_\gamma = 0,
\]
where \(\dot{E}_\gamma\) corresponds to Eq. \((B7)\).

Appendix B: Coefficients of perturbation equations

In this Appendix we show the coefficients of the perturbation equations \((B2)\), \((B3)\), \((B4)\), and \((B5)\).

Eq. \((B2)\)
\[
A_1 = 6H M_{pl}^2 - 3c_3 \phi^3 / M^3 + 45c_4 H \phi^4 / M^6 - 63c_5 H^2 \phi^5 / M^9,
\]
\[
A_2 = c_2 \phi - 9c_3 H \phi^2 / M^3 + 90c_4 H^2 \phi^3 / M^6 - 105c_5 H^3 \phi^4 / M^9,
\]
\[
A_3 = 2M_{pl}^2 + 3c_3 \phi^2 / M^3 - 6c_5 H \phi^5 / M^3,
\]
\[
A_4 = 2\rho_m - 9H^2 M_{pl}^2 - c_1 M^3 \phi / 2 - 3c_2 \phi^2 / 2 + 15c_3 H \phi^3 / M^3 - 315c_4 H^2 \phi^4 / (2M^6) + 189c_5 H^3 \phi^5 / M^9,
\]
\[
A_5 = -2H M_{pl}^2 + c_2 \phi^3 / M - 15c_4 H \phi^4 / M^6 + 21c_5 H^2 \phi^5 / M^9,
\]
\[
A_6 = -c_3 \phi^2 / M^3 + 12c_4 H \phi^3 / M^6 - 15c_5 H^2 \phi^4 / M^9.
\]
\( B_1 = 3A_3 \), \( B_2 = 3A_6 \), \( B_3 = 18HM_{pl}^2 + 27c_4H\dot{\phi}^4/M^6 + 36c_4\dot{\phi}^3\phi/M^6 - 54c_5H^2\dot{\phi}^3/M^6 - 90c_5H\dot{\phi}\phi^4/M^9 - 18c_5\dot{H}\phi^5/M^9 \), \( B_4 = -3c_2\dot{\phi} - 6c_3\dot{\phi}/M^3 + 36c_4\ddot{\phi}\phi^3/M^6 + 108c_4H\dot{\phi}^2\phi/M^6 + 54c_4H^2\phi^3/M^6 - 90c_5H^3\dot{\phi}/M^9 - 180c_5H^2\dot{\phi}^3\phi/M^9 - 90c_5\dot{H}\dot{\phi}^4/M^9 \), \( B_5 = -A_1 \), \( B_6 = 2M_{pl}^2 - c_4\dot{\phi}^4/M^6 - 6c_5\dot{\phi}\phi/M^9 \), \( B_7 = 12c_4\dot{\phi}^2\phi/M^6 + 4c_4H\dot{\phi}^3/M^6 - 6c_5\dot{H}\phi^4/M^9 - 6c_5H^2\dot{\phi}^3/\phi/M^9 - 24c_5\dot{H}^3\dot{\phi}/M^9 \), \( B_8 = A_3 \), \( B_9 = -9H^2M_{pl}^2 - 6\dot{H}M_{pl}^2 - 3\dot{\rho}_m + 3c_1M^3\phi/2 + 3c_2\dot{\phi}^2/2 + 9c_3\dot{\phi}^2\phi/M^3 - 135c_4H^2\dot{\phi}/(2M^6) - 180c_4H\dot{\phi}\phi^3/M^6 - 45c_4\dot{H}\phi^4/M^6 + 315c_5H^2\dot{\phi}^3\phi/M^9 + 126c_5H^3\dot{\phi}/M^9 + 126c_5\dot{H}\dot{\phi}^5/M^9 \), \( B_{10} = -A_3 \), \( B_{11} = -2HM_{pl}^2 - 3c_4\dot{H}\phi^4/M^6 - 12c_4\dot{\phi}^2\phi/M^6 + 6c_5\dot{H}\phi^5/M^9 + 30c_5\dot{H}^2\dot{\phi}/M^9 + 6c_5H^2\dot{\phi}^3/M^9 \).

\[ C_1 = A_3, \quad C_2 = A_6, \quad C_3 = -A_1/3, \quad C_4 = -c_2\dot{\phi} + 3c_3H\dot{\phi}^2/M^3 - 18c_4H^2\dot{\phi}/M^9 + 15c_5H^3\dot{\phi}/M^9. \]

\[ D_2 = c_2 - 6c_3H\dot{\phi}/M^3 + 54c_4H^2\phi^2/M^6 - 60c_5\dot{H}\dot{\phi}/M^9, \quad D_3 = 3c_2\dot{\phi} - 18c_3H\dot{\phi}^2/M^3 - 6c_3\dot{\phi}\phi/M^3 + 108c_4H\dot{\phi}^2\phi/M^6 + 162c_4H^2\dot{\phi}^3/M^6 + 36c_4\ddot{H}\dot{\phi}^3/M^6 - 90c_5(H\dot{H}\phi^4/M^9 + 2H^3\dot{\phi}^4/M^9 + 2H^2\dot{\phi}\phi/M^9), \quad D_4 = 3c_2H - 6c_3\dot{H}\phi/M^3 - 18c_3H^2\dot{\phi}/M^3 - 6c_3\dot{H}\phi/M^3 + 162c_4H^3\dot{\phi}^2/M^6 + 108c_4H\dot{H}\dot{\phi}^2/M^6 + 108c_4H^2\dot{\phi}\phi/M^6 - 180c_5(H^2\dot{\phi}\phi^3/M^9 + H^2\dot{\phi}\phi/M^9 + H^4\phi^3/M^9), \quad D_5 = -A_2, \quad D_6 = -A_6, \quad D_7 = B_7, \quad D_8 = 3c_1M^3/2 + 3c_2\dot{\phi} + 9c_2H\dot{\phi} - 27c_3H^2\dot{\phi}^2/M^3 - 18c_3H\dot{\phi}\phi/\phi^3/3 - 9c_3H\dot{\phi}/M^3 + 162c_4H^2\dot{\phi}/M^9 + 162c_4H^3\phi/M^9 + 108c_4H\dot{H}\dot{\phi}^3/M^6 - 180c_5H^3\dot{\phi}^3/M^9 - 135c_5(H^3\dot{H}\phi^4/M^9 + H^4\phi^4/M^9), \quad D_9 = c_2 - 4c_3H\dot{\phi}/M^3 - 2c_3\dot{\phi}\phi/M^3 - 12c_4H^2\dot{\phi}^2/M^6 + 12c_4H\dot{\phi}/M^6 + 24c_4H\dot{\phi}\phi/M^6 - 36c_5H^2\dot{\phi}/M^9 - 24c_5(H^3\dot{\phi}^3/M^9 + H\dot{H}\phi^3/M^9), \quad D_{10} = A_6, \quad D_{11} = c_1M^3/2 - 3c_2H\dot{\phi} - c_2\dot{\phi} + 27c_3H^2\phi^2/M^3 + 18c_3H\dot{\phi}\phi/M^3 + 9c_3\dot{H}\phi^2/M^3 - 180c_4H\dot{H}\phi^3/M^6 - 270c_4(H^2\phi^2/M^6 + H^3\phi^2/M^6) + 420c_5H^3\phi^2/M^9 + 315c_5(H^4\phi^4/M^9 + H^2\dot{H}\phi/M^9), \quad D_{12} = -c_2\dot{\phi} + 4c_3H\dot{\phi}^2/M^3 + 2c_3\dot{\phi}\phi/M^3 - 30c_4H^2\dot{\phi}/M^6 - 36c_4H\dot{\phi}^2\phi/M^6 - 12c_4H\dot{\phi}^3/M^6 + 30c_5(HH\phi^3/M^9 + H^3\phi^3/M^9 + 2H^2\phi^3\phi^3/M^9). \]
