Lyapunov Function Partial Differential Equations for Chemical Reaction Networks: Some Special Cases

Zhou Fang† and Chuanhou Gao†

Abstract. In this paper we develop a method to generate the Lyapunov function for stability analysis for chemical reaction networks. Based on the Chemical Master Equation, we derive the Lyapunov Function partial differential equations (PDEs), whose solution approximates the scaling non-equilibrium potential and serves as the candidate Lyapunov function for the given network. We further prove that for any chemical reaction network the solution (if exists) of the PDEs is dissipative. Moreover, the proposed method of Lyapunov Function PDEs is qualified for analyzing the asymptotic stability of complex balanced networks, all networks with 1-dimensional stoichiometric subspace and some special networks with more than 2-dimensional stoichiometric subspace if some moderate conditions are added. Several examples are presented to illustrate the efficiency of the method.

Key words. chemical reaction network, mass action system, Lyapunov Function PDEs, non-equilibrium potential, stability.

1. Introduction. Chemical reactions networks (CRNs) arise abundantly in the fields including chemistry, systems biology, process industry, and even those seemingly irrelevant to chemistry such as mechanics and ecology. The dynamics of a CRN often appears to be extremely complex due to chemical interactions of cellular processes but sometimes still exhibiting certain regular behaviors like period solutions and stable-fixed-points. As a special subclass, mass-action CRNs (CRNs assigned mass action kinetics, often named mass action systems) have the dynamics of the concentrations of the various species captured by polynomial ordinary differential equations (ODEs), and have received much attention since the pioneering work [10–12,18] emerged. A major concern over this class of systems is to understand the relations between network structures and/or parameters and dynamical properties [6,7,28], especially in characterizing the stability (in the sense of Lyapunov) property [1,2,18,24,27,29]. Following this line of study, we also focus on capturing stability of equilibria in mass action systems (MASs) in the current work. Naturally, Lyapunov functions are desirable objects to prove stability of equilibria. In the field of CRNs, one important example is the pseudo-Helmholtz free energy function, proposed by Horn and Jackson [18]. This Lyapunov function can be derived from the microscopic level using potential theory [2]. Here, we build further on this, and provide a general theory that bridges between the microscopic and the macroscopic level, thermodynamics and potential theory. Based on it, it is possible to derive or find a Lyapunov function for any MAS.

The early work on stability analysis mainly focused on exploring causal association from the network topology to the distribution of equilibria, and further to stability of equilibria. Thereinto, the weakly reversible structure, a requirement of complex balanced MAS, is the
most active one. Horn et al. [18] proved the well-known Deficiency Zero Theorem that states a weakly reversible deficiency zero MAS to be complex balanced and to have only one equilibrium in each positive stoichiometric compatibility class. Moreover, each equilibrium in the complex balanced system is locally asymptotically stable, for which the pseudo-Helmholtz free energy function is proposed as the Lyapunov function. Feinberg [12] extended this theorem to the well-known Deficiency One Theorem that suggests a weakly reversible MAS to admit a sole equilibrium in each positive stoichiometric compatibility class if some required conditions on network deficiency (not necessary to be zero) are satisfied. Based on these results, the global asymptotical stability of equilibria in a complex balanced MAS was further obtained [26,27] if the network is assumed to be persistent [8,11,15,23], i.e., no stable boundary equilibrium if the initial point is in the interior of $\mathbb{R}_{\geq 0}^n$. Except for the weakly reversible structure, the reversible one, which acts as a special case of the former and is a requirement of detailed balanced MASs, is also the focus of attention. Feinberg [13] derived necessary and sufficient conditions, i.e., circuit conditions and spanning forest conditions, to say a reversible MAS to be detailed balanced. Recently, van der Schaft et al. [29] revisited this class of systems, and reported a compact formulation to describe the dynamics utilizing the graph theory (complex graph). The locally asymptotic stability of detailed balanced networks follows naturally from the fact that they are also complex balanced. Still, the pseudo-Helmholtz free energy function serves as the Lyapunov function.

An important means for stability analysis of a MAS is to construct a Lyapunov function according to the network structure. Although the pseudo-Helmholtz free energy function is capable for rendering asymptotical stability of MASs equipped with the weakly reversible or reversible structure, it fails to serve for those networks, like $3S_2 \rightarrow 3S_1 \rightarrow 2S_1 + S_2$, where $S_1$ and $S_2$ are the species. Clearly, this network is neither weakly reversible nor reversible. We name MASs with general structure (not necessarily weakly reversible or reversible) as balanced MASs if an equilibrium is admitted. For balanced MASs, Angeli and his coauthor [1] proposed Piecewise Linear in Rates Lyapunov Functions for stability analysis. The existence of such functions (they defined the networks having this attribute as $\mathcal{P}$ network set, which is actually a subset of balanced MASs) can guarantee stability of equilibrium, and further serves to establish asymptotical stability within the corresponding positive stoichiometric compatibility class if the Lyapunov function satisfies the LaSalle’s condition. Another possible solution to address the stability problem of a balanced MAS comes from the concept of realization presented by Szederkényi et. al. [28]. It is possible to find a complex balanced or detailed balanced realization for the network in question, then its asymptotical stability holds based on the dynamics equivalence between the network and its realization.

Different from all of the above investigations stemming from macroscopic deterministic analysis, some literature contributes to explaining the system properties from a microscopic stochastic viewpoint. Li and Yi [20,21] connected the strength of attractions to the global attractor with the stationary distribution of a diffusion system, in which a white noise is added to the deterministic case. In the meanwhile, Anderson et. al. [2], starting from a Markov chain model, managed to design a Lyapunov function from a microscopic stochastic concept related to CRNs, termed as non-equilibrium potential that equals to the minus logarithm of stationary distribution of state. They proved that the scaling limit of non-equilibrium potential could act as a Lyapunov function for some MASs. Moreover, such a limit value coincides with the
well-known pseudo-Helmholtz free energy function in the case of complex balanced MASs. This design thought is also valid for general birth-death MASs and some examples of non-complex and non-detailed balanced MASs. These encouraging results motivate us to find a Lyapunov function for MASs rooted in their microscopic concepts. In this paper, we take an approximation of the scaling non-equilibrium potential directly as a possible Lyapunov function and carry out this idea on Chemical Master Equation. A partial differential equation (PDE) is thus derived with the solutions serving as candidate Lyapunov functions. We have further proved the equation solutions dissipative, and able to serve as Lyapunov functions for complex balanced MASs, all networks with 1-dimensional stoichiometric subspace and some special networks with more than 2-dimensional stoichiometric subspace if some moderate conditions are added.

The remainder of this paper is organized as follows. Section 2 revisits some basic concepts about CRNs and the macroscopic deterministic dynamics of network derived from microscopic stochastic model. This is followed by the development of the Lyapunov Function PDEs in Section 3. Section 4 devotes to analyzing the property of solutions of the Lyapunov Function PDEs, and applications to complex balanced MASs. In Section 5, we discuss the validity of the Lyapunov Function PDEs for CRNs with 1-dimensional stoichiometric subspace, and further prove their efficacy in some special examples of CRNs with more than 2-dimensional stoichiometric subspace in Section 6. Finally, conclusions and a conjecture to say the validity of the Lyapunov Function PDEs to general balanced MASs are summarized in Section 7.

Mathematical Notation:

\( \mathbb{R}^n, \mathbb{R}_{n\geq 0}, \mathbb{R}_{n>0} \) : \( n \)-dimensional real space, nonnegative and positive real space, respectively.

\( x^{vi} : x^{vi} = \prod_{j=1}^{d} x_j^{v_{ji}}, \) where \( x, v_i \in \mathbb{R}^d \) and \( 0^0 \) is defined to be 1.

\( \ln(x) : \ln(x) = (\ln x_1, \ln x_2, \cdots, \ln x_d)^\top, \) where \( x \in \mathbb{R}_{>0}^d. \)

\( \otimes \) : Cartesian product.

\( \mathcal{C}^i \) : The function set whose elements are \( i \)-th continuous differentiable.

\( 0_n \) : \( n \)-dimensional vector with every entry to be zero.

2. Preliminary on CRNs. In this section, we will sketch some basic concepts about CRNs [14] and revisit the macroscopic dynamics of mass-action CRNs based on the microscopic analysis [2].

2.1. Basic Concepts. Consider a network with \( n \) species, denoted by \( \{S_1, \cdots, S_n\} \), and \( r \) chemical reactions with the \( i \)th reaction \( R_i \) written as

\( \Sigma_{j=1}^{n} v_{ji} S_j \rightarrow \Sigma_{j=1}^{n} v'_{ji} S_j, \)

where \( v_i, v'_i \in \mathbb{Z}_{\geq 0}^n \) represent the complexes of reactant and resultant, respectively, of this reaction. Note that we label each reaction as a unidirectional reaction, here. If the \( i \)th reaction is reversible, the reverse reaction is naturally covered by exchanging \( v_i \) and \( v'_i \) in the reaction.

Based on the above information, some basic concepts about CRNs may be defined [14].
Definition 1 (Chemical Reaction Network). Denote the finite sets of species, complexes and reactions by $S = \{S_1, S_2, \cdots, S_n\}$, $C = \bigcup_{i=1}^{r} \{v_i, v_i'\}$ and $R = \{v_1 \to v_1', \cdots, v_r \to v_r'\}$, respectively, and $\text{Card}(C) = c$. If the following conditions hold

(i) There is no reaction $v_i \to v_i' \in R$ ($i = 1, \cdots, r$) such that $v_i = v_i'$;
(ii) The $j$th ($j = 1, \cdots, n$) entry of $v_i$ represents the stoichiometric coefficient of species $S_j \in S$ in complex $v_i$,
then the triple $(S, C, R)$ is called a chemical reaction network.

Definition 2 (Stoichiometric Subspace). For a CRN $(S, C, R)$, the linear subspace $\mathcal{S} = \text{span}\{v_1 - v_1', \cdots, v_r - v_r'\}$ is called the stoichiometric subspace of the network.

Definition 3 (Stoichiometric Compatibility Class). Let $\mathcal{S}$ be the stoichiometric subspace of a CRN $(S, C, R)$ and $C \in \mathbb{R}_{\geq 0}^n$ be a nonnegative $n$-dimensional vector, then $C + \mathcal{S} = \{C + \xi | \xi \in \mathcal{S}\}$ is a stoichiometric compatibility class of $C$ for the network; $(C + \mathcal{S}) \cap \mathbb{R}_{\geq 0}^n$ is a nonnegative stoichiometric compatibility class and $(C + \mathcal{S}) \cap \mathbb{R}_{>0}^n$ is a positive stoichiometric compatibility class.

When a CRN is assigned a mass action kinetics, the rate for reaction $v_i \to v_i'$ is evaluated by $k_i x^{v_i}$, where $k_i \in \mathbb{R}_{>0}$ is the rate constant for this reaction, $x \in \mathbb{R}_{\geq 0}^n$ is the vector of concentrations $x_j$ of the chemical species $S_j$, $j = 1, \cdots, n$, and

$$x^{v_i} := \prod_{j=1}^{n} x_j^{v_{ji}}.$$

Definition 4 (Mass Action System). Denote the set of reaction rate constants by $K = (k_1, \cdots, k_r)$ with $k_i$ representing the rate constant for reaction $v_i \to v_i'$, $i = 1, \cdots, r$. A CRN $(S, C, R)$ taken together with the set of reaction rate constants $K$ is called a mass action system, referred to as $(S, C, R, K)$.

The dynamics of a MAS $(S, C, R, K)$ that captures the changes of concentrations of every species over time $t$ is thus expressed as

$$\frac{dx}{dt} = \Gamma R(x), \quad x \in \mathbb{R}_{\geq 0}^n,$$

where $\Gamma \in \mathbb{Z}_{n \times r}$ is the stoichiometric matrix, defined by $\Gamma_{ij} = v_i' - v_i$, and $R(x)$ is $r$-dimensional vector-valued function with $R_i(x) = k_i x^{v_i}$.

Definition 5 (Balanced MAS). For a MAS $(S, C, R, K)$, a vector of concentrations $x^* \in \mathbb{R}_{>0}^n$ is called an equilibrium if its dynamical equation (1) satisfies $\Gamma R(x^*) = 0$. A MAS that admits an equilibrium is said to be a balanced MAS.

Definition 6 (Complex Balanced MAS). For a MAS $(S, C, R, K)$, a vector of concentrations $x^* \in \mathbb{R}_{>0}^n$ is called a complex balanced equilibrium if at this state the combined rate of outgoing reactions from any complex is equal to the combined rate of incoming reactions to it, i.e.

$$\sum_{\{i | v_i = z\}} k_i(x^*)^{v_i} = \sum_{\{i | v_i' = z\}} k_i(x^*)^{v_i'}, \quad \forall z \in C.$$

A MAS that admits a complex balanced equilibrium is said to be a complex balanced MAS.
Eq. (1) succeeds in modeling the CRN systems in the macroscopic level. In the following subsection, we revisit its connection with the dynamic equation that models microscopic CRN systems.

2.2. From Microscopic Stochastic Model to Macroscopic Deterministic Dynamics. In microscopic molecular level, a chemical reaction network system is commonly modeled by a continuous-time Markov chain, following which every reaction takes place like a Poisson process [4, 9]. It allows for counting the frequency that every reaction \( R_i \) \( (i = 1, \ldots, r) \) takes place from initial time 0 to time \( t \) as

\[
F_i(t) = \Omega_i \left( \int_0^t \lambda_i(N(\tau))d\tau \right),
\]

where \( N \in \mathbb{Z}_{\geq 0}^n \) is the vector of numbers of molecules \( N_j \) of every species \( S_j, j = 1, \ldots, n \), indicating the state of the microscopic system, \( \{\Omega_i(\cdot)\}_{i=1,\ldots,r} \) are independent unit-rate Poisson processes that characterizes reactions, and \( \lambda_i(N) \in \mathbb{R}_{\geq 0} \) is a intensity function reflecting the transition extent of \( R_i \). The update for the state \( N(t) \) is thus expressed, according to mass balance, as

\[
N(t) = N(0) + \sum_{i=1}^{r} F_i(t)(v'_i - v_i)
\]

\[
= N(0) + \sum_{i=1}^{r} \Omega_i \left( \int_0^t \lambda_i(N(\tau))d\tau \right) (v'_i - v_i).
\]

This representation is often referred to as the stochastic model of a chemical reaction network system in the sense of microscopic level. Clearly, if \( N(0) \in \mathbb{R}^n_{\geq 0} \), then \( N(t) \in (\mathbb{C} + \mathcal{S}) \cap \mathbb{R}^n_{\geq 0} \), i.e., up to explosion of the process. We thus restrict the subsequent discussion in case of non-explosive processes. In fact, this is not too strict for a Markov Chain. The explosive time can be almost surely infinite if some conditions are satisfied, such as that every transition intensity \( \lambda_i(N(t)) \) is bounded, and that the system is irreducible and finite time recurrent. The mass action kinetics indicates the intensity function to be modeled by

\[
\lambda_i(N) = \tilde{k}_i \prod_{j=1}^{n} \frac{N_j!}{(N_j - v_{ji})!} \mathbb{1}_{\{N_j \geq v_{ji}\}},
\]

where \( \tilde{k}_i \in \mathbb{R}_{>0} \) is termed the microscopic rate constant and \( \mathbb{1}_{\{N_j \geq v_{ji}\}} \) is the characteristic function, defined by

\[
\mathbb{1}_{\{N_j \geq v_{ji}\}} = \begin{cases} 1, & N_j \geq v_{ji}, \\ 0, & N_j < v_{ji}. \end{cases}
\]

So long as the process is non-explosive, the stochastic model of (4) is equivalent to the corresponding Kolmogorov’s forward equation [4], often called Chemical Master Equation, that describes the probability distribution \( P(N,t) \) of \( N(t) \) as

\[
\frac{dP(N,t)}{dt} = \sum_{i=1}^{r} \lambda_i(N + v_i - v'_i)P(N + v_i - v'_i, t) - P(N,t) \sum_{i=1}^{r} \lambda_i(N).
\]
Definition 7 (Stationary Distribution). A probability distribution \( \pi(N) \) is a stationary distribution for the Markov chain on \((N(0) + \mathcal{S}) \cap \mathbb{R}_{\geq 0}^n \) if it satisfies

\[
\sum_{i=1}^{r} \lambda_i(N + v_i - v_i') \pi(N + v_i - v_i') - \pi(N) \sum_{i=1}^{r} \lambda_i(N) = 0,
\]

where \( \pi(N + v_i - v_i') = 0 \) if \( N + v_i - v_i' \notin (N(0) + \mathcal{S}) \cap \mathbb{R}_{\geq 0}^n \).

The ergodic property of the continuous-time Markov chain states [25] that if the chain on \((N(0) + \mathcal{S}) \cap \mathbb{R}_{\geq 0}^n \) is irreducible and recurrent, then \( \pi(N) \) exists and is unique.

We then revisit the macroscopic deterministic dynamics of the underlying MAS derived from the microscopic stochastic model of (4) by neglecting the random part under an appropriate scaling level. The differential form of (4) can be divided into two parts [22]: the first one is the deterministic part \( \tilde{\pi}(t) \), i.e., the drift (expectation) rate, satisfying

\[
\tilde{\pi}(t) \triangleq \lim_{dt \to 0^+} \frac{\text{E}[N(t + dt) - N(t)|N(t)]}{dt} = \sum_{i=1}^{r} \lambda_i(N(t)) (v_i' - v_i),
\]

while the second one is the random part \( \hat{\pi}(t) \), related to the following standard deviation rate

\[
\hat{\pi}(t) \triangleq \sqrt{\lim_{dt \to 0^+} \text{Var}[N(t + dt) - N(t)|N(t)] / dt} = \sqrt{\sum_{i=1}^{r} \lambda_i(N(t)) (v_i' - v_i)(v_i' - v_i)^\top},
\]

in which \( \text{Var} \) is the variance operator. Note that \( \sum_{i=1}^{r} \lambda_i(N(t)) (v_i' - v_i)(v_i' - v_i)^\top \) is positive semi-definite, so \( \hat{\pi}(t) \) must exist.

As the scale level increases, such as increasing from the molecular level to molar level, the random part \( \tilde{\pi}(t) \), compared to the deterministic part \( \hat{\pi}(t) \), contributes to the system smaller and smaller, and can be ignored at last. Also, note the fact that \( N_j(t) \gg v_{ji}, \forall i, j \), then the stochastic model of (4) can be well approximated by a deterministic one [5] that describes the evolution of concentration vector \( x(t) = \frac{N(t)}{N_0V} \), written as

\[
\frac{dx(t)}{dt} = \frac{r}{V} \sum_{i=1}^{r} k_i(A_{i\mathcal{V}})^{|v_i| - 1} \prod_{j=1}^{n} x_j^{v_{ji}} (v_i' - v_i) = \sum_{i=1}^{r} k_i x_i^{v_i} (v_i' - v_i),
\]

where \( A_{i\mathcal{V}} \) is the Avogadro constant, \( V \) the volume of the system, \( |v_i| \) indicates the sum of entries of vector \( v_i \), \( k_i = \tilde{k}_i(A_{i\mathcal{V}})^{|v_i| - 1} \) is the reaction rate coefficient for the \( i \)th reaction in the meaning of macroscopic level and \( x_i^{v_i} = \prod_{j=1}^{n} x_j^{v_{ji}} \) which indicates the mass-action kinetics. This expression is exactly the same as given in Eq. (1). More details about the derivation from the microscopic model to the macroscopic one may be referred to [5].

One point needs to be noted that although it is a fact that the continuous-valued deterministic equation (9) arises from the discrete probability model (7), the transformation between these two extremes are poorly understood. Some simulation analysis may be found in [17], and some connections between deterministic models and stochastic counterpart can be found in [19–21].
3. Lyapunov Function PDEs. This section contributes to deriving Lyapunov function PDEs for CRNs assigned mass action kinetics based on the relations between some microscopic concepts and macroscopic ones.

3.1. Lyapunov Function Derived from Stationary Distribution for Complex Balanced MASs. The CRNs theory [4,9] reveals that there exists close relation between the microscopic stochastic dynamics and the macroscopic deterministic dynamics. Motivated by this fact, Anderson et al. [2] derived a Lyapunov function, a macroscopic concept, from the stationary distribution, a microscopic notion, for the stability analysis of complex balanced MASs.

From the viewpoint of the macroscopic dynamics (9), a MAS is complex balanced if \( \exists x^* \in \mathbb{R}^n_{>0} \) such that for \( \forall z \in \mathcal{C} \) there is

\[
\sum_{\{i|v \cdot i = z\}} k_i (x^*)^{v \cdot i} = \sum_{\{i|v' \cdot i = z\}} k_i (x^*)^{v' \cdot i}.
\]

For this class of MASs, the pseudo-Helmholtz free energy function, defined by

\[
G(x) = \sum_{j=1}^{n} x_j (\ln(x_j) - \ln(x_j^*) - 1) + x_j^*,
\]

is a frequently-used Lyapunov function [18]. Despite a macroscopic concept, the pseudo-Helmholtz free energy function can be derived from the stationary distribution, a microscopic notion. As an example of a complex balanced MAS that admits an equilibrium of \( x^* \) [3], the stationary distribution \( \pi(N) \) can be solved from (8) as

\[
\pi(N) = M \prod_{j=1}^{n} \frac{x_j^* N_j}{N_j!},
\]

where \( M \in \mathbb{R}_{>0} \) is a normalization factor. The non-equilibrium potential is thus expressed as

\[
-\ln(\pi(N)) = -\ln M - \sum_{j=1}^{n} \ln \frac{x_j^* N_j}{N_j!}.
\]

Further, Anderson et al. [2] proved that the scaling limit of non-equilibrium potential coincides with the pseudo-Helmholtz free energy function, i.e.,

\[
\lim_{A_vV \to \infty} -\frac{1}{A_vV} \ln (\pi(A_vVx)) = G(x).
\]

They also asserted that the scaling limit of non-equilibrium potential can suggest a Lyapunov function for the birth-death processes and some other special cases of non-complex balanced MASs [2].

Generally speaking, the scaling limit of non-equilibrium potential provides a very effective way for some MASs to achieve the Lyapunov function with a definite physical meaning. However, it seems not easy to apply this method to more general MASs, because solving the stationary Chemical Master Equation (8) is usually a difficult task. To avoid this difficulty, we
propose an alternative method, that is taking an approximation of the scaling non-equilibrium potential \(-\frac{1}{A_v} \ln (\pi(A_v x))\) as a candidate Lyapunov function. Note that the former is naturally defined on a discrete set \(\{x|A_v V x \in \mathbb{Z}_{\geq 0}^n\}\) while the latter is a continuous function defined on \(\{x|x \in \mathbb{R}_{\geq 0}^n\}\). Obviously, the proposed method does not need to know the explicit expression of a stationary distribution, but only requires to know that a positive stationary distribution is existing. We will follow this idea to derive Lyapunov function PDEs, and further solve Lyapunov functions for stability analysis of more general MASs below.

### 3.2. Derivation of Lyapunov Function PDEs.

The approximation of the scaling non-equilibrium potential may be performed on the Chemical Master Equation (7) of a MAS \((S, C, R, K)\). Through dividing (7) by \(-P(N,t)A_v V\), we can rewrite this equation as

\[
\frac{d}{dt} \left( -\frac{\ln (P(N,t))}{A_v V} \right) = \sum_{i=1}^r \frac{\lambda_i(N)}{A_v V} - \sum_{i=1}^r \frac{\lambda_i(N + v_i - v'_i)}{A_v V} P(N + v_i - v'_i, t) P(N,t),
\]

which is actually an ordinary differential equation about the scaling non-equilibrium potential. Assume that there exists a positive stationary distribution \(\pi(N)\) for each stoichiometric compatibility class characterizing the MAS of interest, i.e., the non-equilibrium potential exits. For simplicity of notations, denote the scaling non-equilibrium potential by \(L(x) = -\frac{1}{A_v} \ln (\pi(A_v x))\), and then by inserting it into (13) we get

\[
\frac{dL(x)}{dt} = 0
= \sum_{i=1}^r \frac{\lambda_i(A_v V x)}{A_v V} - \frac{\lambda_i(A_v V x + v_i - v'_i)}{A_v V} \exp \left\{ \frac{L(x) - L(x + (v_i - v'_i)/A_v V)}{1/A_v V} \right\}.
\]

Let a continuous differentiable function \(f \in \mathcal{C}^1(\mathbb{R}_{\geq 0}^n)\) approximate the above function \(L(x) (x \in \{y|A_v V y \in \mathbb{Z}_{\geq 0}^n\}\)). Then together with the fact \(A_v V \gg (v_j - v'_j), \forall i,j\), it indicates the exponential term in (14) to be approximated as

\[
\exp \left\{ \frac{f(x) - f(x + (v_i - v'_i)/A_v V)}{1/A_v V} \right\} \approx \exp \left\{ (v'_i - v_i)^\top \nabla f(x) \right\}.
\]

The remaining two terms \(\frac{\lambda_i(A_v V x)}{A_v V}\) and \(\frac{\lambda_i(A_v V x + v_i - v'_i)}{A_v V}\) can be thought as the same in the macroscopic coordinated and be approximated by \(k_i x^{v_i}\). As a result, the Chemical Master Equation of (14) becomes a first-order partial differential equation

\[
\sum_{i=1}^r k_i x^{v_i} = \sum_{i=1}^r k_i x^{v_i} \exp \left\{ (v'_i - v_i)^\top \nabla f(x) \right\} = 0, \quad x \in \mathbb{R}_{\geq 0}^n.
\]

We can alternatively express this PDE according to the complexes set

\[
\sum_{\{i|v_i \in C\}} k_i x^{v_i} - \sum_{\{i|v'_i \in C\}} k_i x^{v_i} \exp \left\{ (v'_i - v_i)^\top \nabla f(x) \right\} = 0, \quad x \in \mathbb{R}_{\geq 0}^n.
\]
Note that the above PDE (15) or (16) is derived from the Chemical Master Equation by setting the solution as an approximation of the scaling non-equilibrium potential. Its existence seems dependent on the existence of the non-equilibrium potential, i.e., on that of a stationary distribution. Although it is quite difficult to know whether a stationary distribution is existing in (8), it will not limit the applicability of the developed theory. We find that the Lyapunov Function PDE (15) or (16) can be also achieved for some systems without the non-equilibrium potential. For example, the following CRN with absorption

\[
S_1 + 2S_2 \rightarrow 3S_2, \\
2S_2 \rightarrow S_1 + S_2,
\]

there will be eventually one of the species \(S_2\) in which case none of the reactions can fire, so the potential does not exist. However, we can write out its Lyapunov Function PDE according to (15) or (16). A reasonable explanation may be that the solution of (8) for this network would be to consider the QSD (quasi-stationary distribution) or a modification where the CRN cannot jump to the state with \(S_2 = 1\). The latter has been done by Anderson et. al. [2] for birth-death processes with absorption. We thus stipulate that for those networks without a stationary distribution, the solution of (8) would be to consider the QSD or a modification of the rates if the PDE is derived using potential theory. In fact, the PDE may be also generated directly from the macroscopic dynamics of the CRN under study. In this sense, there always exists a corresponding PDE (15) for a CRN no matter whether the non-equilibrium potential is existing or not.

To solve a PDE, it usually needs to know the related boundary conditions. For the above one, we still derive its boundary conditions based on the approximation to the Chemical Master Equation. Since it is very hard to directly analyze the boundary conditions for (15), we manage to get an insight into them through the following example of a special MAS.

**Example 1.** Consider a MAS including a first-order reversible reaction \(S_1 \rightleftharpoons S_2\). The species set is \(S = \{S_1, S_2\}\), the complex set having the same form \(C = \{S_1, S_2\}\), and the reaction set is \(R = \{S_1 \rightarrow S_2, S_2 \rightarrow S_1\}\). Using the notations given in Definition 1, the last two sets might be written as \(C = \bigcup_{i=1}^{2}\{v_i, v'_i\}\) and \(R = \{v_1 \rightarrow v'_1, v_2 \rightarrow v'_2\}\), where \(v_1 = v'_2 = (1, 0)^\top\), and \(v_2 = v'_1 = (0, 1)^\top\). The domain of the stochastic model for this network is a nonnegative discrete set \(\{x = (x_1, x_2)\mid A_v x_1, A_v x_2 \in \mathbb{Z}_{>0}\}\), where \(x\) is the vector of molar concentration. It thus defines two subsets of boundary points, denoted by \(M_1 = \{x \mid x_1 = 0, A_v x_2 \in \mathbb{Z}_{>0}\}\) and \(M_2 = \{x \mid A_v x_1 \in \mathbb{Z}_{>0}, x_2 = 2\}\), respectively.

As an example of a boundary point \(\bar{x} \in M_1\), the last state of \(\bar{x}\), just before the last reaction, might be \(A_v \bar{x} + v_2 - v'_2 = (1, A_v x_2 - 1)^\top\) or \(A_v \bar{x} + v_1 - v'_1 = (-1, A_v x_2 + 1)^\top\). By substituting these three states into Eq. (5), we can calculate intensity functions as follows.

\[
\lambda_1(A_v \bar{x}) = \lambda_2(A_v \bar{x} + v_1 - v'_1) = 0, \quad \lambda_1(A_v \bar{x} + v_2 - v'_2) = 0, \quad \lambda_2(A_v \bar{x}) \neq 0, \quad \lambda_2(A_v \bar{x}) \neq 0.
\]

Further, by inserting these intensity functions into Eq. (14), we may get a boundary condition for the Chemical Master Equation of this MAS as

\[
\frac{\lambda_2(A_v \bar{x}) - \lambda_1(A_v \bar{x} + v_1 - v'_1)}{A_v} \exp \left\{ \frac{L(\bar{x}) - L(\bar{x} + (v_1 - v'_1)/A_v)}{1/A_v} \right\} = 0, \quad \bar{x} \in M_1.
\]
Finally, by the approximation scheme from (14) to (15), the above boundary condition can be approximated by

\[
\lim_{x \to \bar{x}, \bar{x} \in \mathbb{R}^{n}_{>0}} k_2 x^{v_2} - k_1 x^{v_1} \exp \left\{ (v'_1 - v_1)^\top \nabla f(x) \right\} = 0, \quad \bar{x} \in \{0\} \times \mathbb{R}_{>0},
\]

which serves as a boundary condition for the PDE of the corresponding system. Similarly, the boundary condition at $\bar{x} \in \mathcal{M}_2$ is presented as

\[
\lim_{x \to \bar{x}, \bar{x} \in \mathbb{R}^{n}_{>0}} k_1 x^{v_1} - k_2 x^{v_2} \exp \left\{ (v'_2 - v_2)^\top \nabla f(x) \right\} = 0, \quad \bar{x} \in \mathbb{R}_{>0} \times \{0\}.
\]

The above example provides a clear insight into how to express the boundary conditions for the PDE (15) or (16), i.e., identifying non-zero intensity functions with the given boundary points set. By Eq. (5), whether or not the reaction’s intensity function $\lambda_i(\cdot)$ is zero depends closely on its complexes. At any boundary point $\bar{x}$, Eq. (5) tells us that the intensities of reactions with the same reactant complex are simultaneously positive or zero. We call the set of complexes which generate positive intensities at boundary point $\bar{x}$ as a boundary complex set of $\bar{x}$, and denoted it by $C_{\bar{x}}$ in the context. The boundary complex set may vary from point to point. Also, from Eq. (5), we can easily find that the intensity $\lambda_i(A_v \bar{x} + v_i - v'_i)$ is positive, only if the resultant complex of the corresponding reaction $v'_i$ lies in the boundary complex set of $\bar{x}$. In Example 1, at the boundary point $(0, x_2)^\top$, only the reaction with reactant complex $(0, 1)^\top$ has positive intensity function. The boundary complex set of $(0, x_2)^\top$ is thus to be $\{(0, 1)^\top\}$. Based on the same analysis, the boundary complex set of $(x_1, 0)^\top$ is $\{(1, 0)^\top\}$. Also, at the boundary point $(0, x_2)^\top$, the intensity function $\lambda_2(A_v \bar{x} + v_2 - v'_2) > 0$ because the resultant complex in the second reaction lies in the corresponding boundary complex set.

With these understandings, we can rewrite Eq. (14) at any boundary point $\bar{x}$ as

\[
\sum_{\{i|v_i \in C_{\bar{x}}\}} \frac{\lambda_i(A_v \bar{x})}{A_v} - \sum_{\{i|v'_i \in C_{\bar{x}}\}} \frac{\lambda_i(A_v \bar{x} + v_i - v'_i)}{A_v} \exp \left\{ \frac{L(\bar{x}) - L (\bar{x} + (v_i - v'_i)/A_v)}{1/A_v} \right\} = 0.
\]

By applying the same approximation scheme used above, we arrive at the boundary condition of the developed PDE (15)

\[
\lim_{x \to \bar{x}, \bar{x} \in \mathbb{R}^{n}_{>0}} \sum_{\{i|v_i \in \{(0,1)^\top\}\}} k_i x^{v_i} - \sum_{\{i|v'_i \in \{(0,1)^\top\}\}} k_i x^{v'_i} \exp \left\{ (v'_i - v_i)^\top \nabla f(x) \right\} = 0,
\]

where $\bar{x}$ is any boundary point lies in the union of all stoichiometric compatibility classes, $\{x \in (y + \mathscr{S}) \cap \mathbb{R}^{n}_{>0} \mid y \in \mathbb{R}^{n}_{>0} \text{ and } x \notin \mathbb{R}^{n}_{>0}\}$. Here, the limit notation is introduced to make the terms well defined in the case where $\nabla f(\cdot)$ does not converge at the boundary point. In Example 1, the boundary condition (17) can be written as

\[
\lim_{x \to \bar{x}, \bar{x} \in \mathbb{R}^{n}_{>0}} \sum_{\{i|v_i \in \{(0,1)^\top\}\}} k_i x^{v_i} - \sum_{\{i|v'_i \in \{(0,1)^\top\}\}} k_i x^{v'_i} \exp \left\{ (v'_i - v_i)^\top \nabla f(x) \right\} = 0.
\]

which falls into the expression (19) and illustrates the correctness of our derivation.
Clearly, identifying the boundary complex set \( C \) plays a key role on formulating the boundary conditions. Generally speaking, it is not easy to identify \( C \), especially when the underlying CRN is complicated. A possible expression for it may be obtained from revisiting (5) where positive intensity function requests \( N_j > v_{ji}, \forall i, j \). We thus can express a particular boundary complex set as

\[
\bar{C} = \{ z \in C \mid \exists \epsilon > 0 \text{ such that } \forall j = 1, \cdots, n, \bar{x}_j \geq \epsilon z_j \}
\]

which is referred to as naive boundary complex set in the context.

The PDE (15) and its boundary condition (19) will serve for generating the Lyapunov function for macroscopic deterministic mass-action CRNs. They are referred to as Lyapunov Function PDEs throughout the paper.

4. Solutions of Lyapunov Function PDEs. This section focuses on analyzing the property and utility of solutions of Lyapunov Function PDEs if they exist.

4.1. Conditions for Solutions to Become Lyapunov Function. We firstly analyze the dissipativeness of solutions of the Lyapunov Function PDEs (15) plus (19), a necessary property for solutions becoming Lyapunov functions, under the assumption that the solutions exist.

**Theorem 8.** For a MAS \((S, C, \mathcal{R}, K)\) described by (9), assume that there exists a solution \( f \in C^1 \) for its Lyapunov Function PDEs (15) plus (19). Then, the solution \( f(x) \) satisfies

\[
\dot{f}(x) = \frac{df(x)}{dt} \leq 0, \quad \forall x \in \mathbb{R}^n_>,
\]

where the equality holds if and only if \( \nabla f(x) \perp S \).

**Proof.** Reorganize the PDE (15) to be

\[
\sum_{i=1}^{r} k_i x^{v_i} \left( 1 - \exp \left\{ (v_i' - v_i)^\top \nabla f(x) \right\} \right) = 0
\]

and further perform the Taylor expansion of \( \exp \left\{ (v_i' - v_i)^\top \nabla f(x) \right\} \) with respect to zero, then we have

\[
\sum_{i=1}^{r} k_i x^{v_i} (v_i' - v_i)^\top \nabla f(x) + \sum_{i=1}^{r} k_i x^{v_i} \frac{\eta_i}{2} [(v_i' - v_i)^\top \nabla f(x)]^2 = 0,
\]

where \( \eta_i \in \mathbb{R} \) lies between 0 and \( (v_i' - v_i)^\top \nabla f(x) \). Since for \( \forall x \in \mathbb{R}^n_> \) there is

\[
\dot{f}(x) = \dot{x}^\top \nabla f(x) = \sum_{i=1}^{r} k_i x^{v_i} (v_i' - v_i)^\top \nabla f(x),
\]

we get

\[
\dot{f}(x) = - \sum_{i=1}^{r} k_i x^{v_i} \frac{\eta_i}{2} [(v_i' - v_i)^\top \nabla f(x)]^2 \leq 0,
\]

where the equality holds if and only if for \( \forall i \), \( (v_i' - v_i)^\top \nabla f(x) = 0 \), i.e., \( \nabla f(x) \perp S \).
Remark 1. The dissipativeness of $f(x)$ means that it has one of the necessary properties to become a Lyapunov function. In addition, this property implies that $-f(x)$ will always increase as time goes by, which further indicates that there may be a close relation between $-f(x)$ and the entropy function, an important concept in thermodynamics. A possible point of future research may be to define or derive the entropy expression based on the Lyapunov Function PDEs instead of the Gibbs’ Equation.

We further derive the conditions that the non-dissipative point of $f(x)$ is the equilibrium point of the MAS.

**Theorem 9.** For a MAS $(S,C,R,K)$ described by (9), assume that its Lyapunov Function PDEs (15) and (19) admit a solution $f \in \mathcal{C}^2$, and moreover, there exists a region $D \subset \mathbb{R}^n_{>0}$ such that $\forall \ x \in D$ and $\forall \ \mu \in \mathcal{S}$ we have

$$\mu^T \nabla^2 f(x) \mu \geq 0 \text{ with equality hold if and only if } \mu = 0_n.$$  

Then, for all $x \in D$, $\dot{f}(x) = 0$ if and only if $x$ is an equilibrium of the MAS.

**Proof.** The necessity is obvious. For the sufficiency, Theorem 8 suggests that for any $x \in D$, $\dot{f}(x) = 0$ if and only if $\nabla f(x) \perp \mathcal{S}$. By taking the derivative of (15) with respect to $x$ on both sides, and further inserting the condition $\nabla f(x) \perp \mathcal{S}$, we have

$$\nabla^2 f(x) \left[ \sum_{i=1}^r k_i x^{v_i} (v'_i - v_i) \right] = 0_n,$$

i.e.,

$$\left[ \sum_{i=1}^r k_i x^{v_i} (v'_i - v_i) \right]^T \nabla^2 f(x) \left[ \sum_{i=1}^r k_i x^{v_i} (v'_i - v_i) \right] = 0.$$

Note that the term $\sum_{i=1}^r k_i x^{v_i} (v'_i - v_i)$ lies in $\mathcal{S}$, so we get $\sum_{i=1}^r k_i x^{v_i} (v'_i - v_i) = 0_n$ from the condition (22), which means that $x \in D$ should be an equilibrium of the MAS. This completes the proof. ■

**Remark 2.** Theorem 9 reveals that for a balanced MAS $(S,C,R,K)$ the solution of its Lyapunov Function PDEs (if exists) is strictly dissipative and, therefore, a good candidate for a Lyapunov function, provided that the solution is twice differentiable and convex in $D \cap (x^* + \mathcal{S}) \cap \mathbb{R}^n_{>0}$.

Finally, we give conditions which indicates the solution to be indeed a Lyapunov function.

**Theorem 10.** For a MAS $(S,C,R,K)$ governed by (9), let $x^* \in \mathbb{R}^n_{>0}$ be one of its equilibrium points. Assume that the Lyapunov Function PDEs (15) and (19) of the MAS admit a solution $f \in \mathcal{C}^2$, and moreover, there exists a region $D = \mathcal{N}(x^*) = \delta(x^*) \cap (x^* + \mathcal{S}) \cap \mathbb{R}^n_{>0}$, where $\delta(x^*)$ is a neighborhood of $x^*$, such that $\forall \ x \in \mathcal{N}(x^*)$ the solution $f(x)$ satisfies (22). Then $f(x)$ can act as a Lyapunov function rendering $x^*$ to be locally asymptotically stable with respect to all initial conditions in $\mathcal{N}(x^*) \cap \{x \mid f(x) < \inf_{y \in \partial \mathcal{N}(x^*)} f(y)\}$. 12
Proof. Since $f(x)$ satisfies (22) in $\mathcal{N}(x^*)$, $f(x)$ is strictly convex in this region. The strict convexity together with the fact, $\nabla f(x^*) \perp \mathcal{S}$ (by Theorem 8), implies the function to be lower bounded by $f(x^*)$. Also, the strict convexity suggests that no other state except $x^*$ can make $\nabla f(x) \perp \mathcal{S}$ and, therefore, that $x^*$ is the sole equilibrium in this region (by Theorem 8). Thus, by theorem 9, this fact states $\dot{f}(x) \leq 0$ with equality hold if and only if $x = x^*$.

For any initial point $x(0) \in \mathcal{N}(x^*) \cap \{x|f(x) < \inf_{y \in \partial \mathcal{N}(x^*)} f(y)\}$, since $\dot{f}(x) \leq 0$, the state trajectory of the mass action system starting from $x(0)$ will be bounded in the region $\mathcal{N}(x^*) \cap \{x|f(x) < \inf_{y \in \partial \mathcal{N}(x^*)} f(y)\}$. Therefore, if $f(x)$ is selected as the Lyapunov function, then $x^*$ is locally asymptotically stable with respect to all initial conditions in $\mathcal{N}(x^*) \cap \{x|f(x) < \inf_{y \in \partial \mathcal{N}(x^*)} f(y)\}$.

It is clear that the Lyapunov Function PDEs (15) and (19) have potentials to generate a solution serving as the Lyapunov function for MASs with some moderate conditions satisfied. We try our hands at a class of special MASs, i.e., complex balanced MASs, to test the method of the PDEs in the following.

4.2. Test on Complex Balanced MASs. We will demonstrate that the Lyapunov Function PDEs work for complex balanced MASs. As mentioned in Section 3.1, a complex balanced MAS admits an equilibrium $x^*$ satisfying the relation (2). Moreover, the equilibrium was proved locally asymptotically stable through taking the pseudo-Helmholtz free energy function as the Lyapunov function [18, 24]. To show the power of Lyapunov function PDEs, we verify that the pseudo-Helmholtz free energy function is one of their solutions.

Theorem 11. For a MAS $(S, C, R, K)$ that admits a complex balanced equilibrium $x^* \in \mathbb{R}^n_+$, the pseudo-Helmholtz free energy function of (11) is a solution of the corresponding Lyapunov Function PDEs (15) (or equivalently (16)) and (19) whatever the boundary complex set is.

Proof. For $\forall \ x \in (x(0) + \mathcal{S}) \cap \mathbb{R}^n_+$, the gradient of the pseudo-Helmholtz free energy function is

$$\nabla G(x) = \ln \left(\frac{x}{x^*}\right) = \left(\ln \left(\frac{x_1}{x^*_1}\right), \ln \left(\frac{x_2}{x^*_2}\right), \cdots, \ln \left(\frac{x_n}{x^*_n}\right)\right)^\top.$$ 

Plugging it into the left hand side (L.H.S) of (16) yields

L.H.S of Eq. (16) = \sum_{\{i|v_i \in C\}} k_i x^{v_i} - \sum_{\{i|v'_i \in C\}} k_i x^{v_i} \exp \left\{ (v'_i - v_i) \top \ln \left(\frac{x}{x^*}\right) \right\}

= \sum_{z \in C} \left( \sum_{\{i|v_i = z\}} k_i x^{v_i} - \sum_{\{i|v'_i = z\}} k_i x^{v_i} \exp \left\{ (v'_i - v_i) \top \ln \left(\frac{x}{x^*}\right) \right\} \right)

= \sum_{z \in C} \left( \sum_{\{i|v_i = z\}} k_i x^{v_i} - \left(\frac{x}{x^*}\right)^z \sum_{\{i|v'_i = z\}} k_i (x^*)^{v_i} \right)

= \sum_{z \in C} \left(\frac{x}{x^*}\right)^z \left[ \sum_{\{i|v_i = z\}} k_i (x^*)^{v_i} - \sum_{\{i|v'_i = z\}} k_i (x^*)^{v_i} \right] = 0,

13
where the last equality follows immediately from the complex balanced condition (2). Hence, 
\( G(x) \) satisfies the PDE of (16) and (15).

We further verify that \( G(x) \) satisfies the boundary condition of (19). Let \( \mathcal{C}_x \) be a boundary complex set induced by any boundary point \( \bar{x} \), then the left hand side of (19) is
\[
\lim_{x \to \bar{x}} \sum_{z \in \mathcal{C}_x} \left( \sum_{i \{v_i = z\}} k_i x^{v_i} - \sum_{i \{v_i' = z\}} k_i x^{v_i'} \exp \left\{ (v_i' - v_i) \mathsf{T} \ln \left( \frac{x}{x} \right) \right\} \right) = 0.
\]
Note that the above equations hold independent of the choice of \( \mathcal{C}_x \), which completes the proof.

It is well-known that the pseudo-Helmholtz free energy function is a Lyapunov function for a complex balanced MAS and succeeds in analyzing the system’s asymptotic stability [18]. This stability result can be also reached through the method of the Lyapunov Function PDEs.

**Theorem 12.** For a MAS \( (\mathcal{S}, \mathcal{C}, \mathcal{R}, \mathcal{K}) \) possessing a complex balanced equilibrium \( x^* \in \mathbb{R}^{n>0} \), the Lyapunov function PDEs (15) plus (19) have a solution (11) that can serve as a Lyapunov function to suggest this system to be locally asymptotically stable at \( x^* \) with respect to all initial conditions in \( (x^* + \mathcal{S}) \cap \mathbb{R}^{n>0} \) near \( x^* \).

**Proof.** As proved in Theorem 11, the pseudo-Helmholtz free energy function \( G(x) \) defined by (11) is a solution of the Lyapunov function PDEs (15) plus (19). Obviously, \( G(x) \) is twice differentiable, and its Hessian matrix is calculated as
\[
\nabla^2 G(x) = \begin{pmatrix} \frac{1}{x_1} & \cdots & \frac{1}{x_n} \end{pmatrix}.
\]
Clearly, \( \forall x \in (x^* + \mathcal{S}) \cap \mathbb{R}_{>0} \), \( \nabla^2 G(x) \) is positive definite. This means that (22) is true. Further based on Theorem 10, the result is straightforward.

The above two theorems reveal that the Lyapunov Function PDEs method can produce Lyapunov functions (11) for complex balanced MASs and serve for the stability analysis of these systems very well. In this case, the Lyapunov Function PDE (16) becomes
\[
\sum_{z \in \mathcal{C}} e^{z^\mathsf{T} \nabla G(x)} \left( \sum_{i \{v_i = z\}} k_i x^{v_i} e^{-v_i^\mathsf{T} \nabla G(x)} - \sum_{i \{v_i' = z\}} k_i x^{v_i'} e^{-v_i'^\mathsf{T} \nabla G(x)} \right) = 0, \quad x \in \mathbb{R}^{n>0}.
\]
Further by combining (2), we get \( k_i x^{v_i} = k_i (x^*)^{v_i} \exp \left\{ v_i^\mathsf{T} \nabla G(x) \right\} \). This relational expression can be also found in Gorboan’s work [16], which connects the reaction rate at any concentration with that at the equilibrium concentration through the entropy-like function \( G(x) \).
\( \nabla G(x) = 0_n \), every complex will reach reaction balance. At this point, \( \nabla G(x) \) plays a role on driving the reaction to occur towards equilibrium for every complex.

**5. Lyapunov Function PDEs for CRNS with \( \dim \mathcal{S} = 1 \).** The Lyapunov function PDEs are studied for CRNs with one dimensional stoichiometric subspace in this section.

**Proposition 13.** For a MAS \((S, C, R, K)\) with \( \dim \mathcal{S} = 1 \), the Lyapunov Function PDEs are

\[
(u - 1) \left[ \sum_{\{i | m_i > 0\}} (k_i x^{v_i}) \left( \sum_{j=0}^{m_i-1} u^j \right) + \sum_{\{i | m_i < 0\}} (k_i x^{v_i}) \left( - \sum_{j=m_i} u^j \right) \right] = 0
\]

plus the boundary condition

\[
\lim_{x \rightarrow \bar{x}} \sum_{\{i | m_i > 0\}} k_i x^{v_i} \sum_{\{i | v_i, v_i' \in C \}} k_i x^{v_i} u^{m_i} = 0,
\]

where \( u = \exp\{w^\top \nabla f\}, w \in \mathbb{R}^n \setminus \{0_n\} \) represents a set of bases of \( \mathcal{S} \) and \( m_i \in \mathbb{Z} \setminus \{0\}, i = 1, \ldots, r \), satisfy

\[
v_i' - v_i = m_i w.
\]

**Proof.** When \( \dim \mathcal{S} = 1 \), any element among \( \{v_1' - v_1, \ldots, v_r' - v_r\} \) can be used to express linearly the remaining \( r - 1 \) ones. Therefore, there must exist a \( w \in \mathbb{R}^n \setminus \{0_n\} \) acting as a set of bases of \( \mathcal{S} \) such that

\[
v_i' - v_i = m_i w, \quad \forall i = 1, \ldots, r, m_i \in \mathbb{Z} \setminus \{0\}.
\]

In this case, the PDE of \((15)\) becomes

\[
\sum_{i=1}^{r} k_i x^{v_i} \left( 1 - e^{m_i (w^\top \nabla f(x))} \right) = 0,
\]

i.e.,

\[
\sum_{\{i | m_i > 0\}} k_i x^{v_i} \left( 1 - e^{m_i (w^\top \nabla f(x))} \right) + \sum_{\{i | m_i < 0\}} k_i x^{v_i} \left( 1 - e^{m_i (w^\top \nabla f(x))} \right) = 0.
\]

By setting \( u = e^{w^\top \nabla f(x)} \), we get the Lyapunov function PDEs \((24)\) plus \((25)\) for CRNs with \( \dim \mathcal{S} = 1 \).

**Corollary 14.** For any constant \( \epsilon \), \( f(x) = \epsilon \) is a solution of the PDE \((24)\).

**Proof.** The result is immediate since \( u = 1 \) is a solution of the PDE.

**Remark 3.** If \( f(x) = \epsilon \) satisfies the boundary condition of \((25)\), then

\[
\lim_{x \rightarrow \bar{x}} \sum_{\{i | m_i > 0\}} k_i x^{v_i} \sum_{\{i | v_i, v_i' \in C \}} k_i x^{v_i} u^{m_i} = 0
\]

This condition is very restrictive that can be hardly reached even in the case of one dimensional stoichiometric subspace. Therefore, the constant solution \( f(x) = \epsilon \) is usually not qualified to follow the boundary condition \((25)\) for a general CRN with \( \dim \mathcal{S} = 1 \).
The above reason motivates us to consider the solution that makes the second term of the L.H.S of (24) vanish, i.e.,

$$
\sum_{\{i|m_i>0\}} (k_i x^{v_i}) \left( \sum_{j=0}^{m_i-1} u^j \right) + \sum_{\{i|m_i<0\}} (k_i x^{v_i}) \left( - \sum_{j=m_i} u^j \right) = 0.
$$

**Proposition 15.** For a MAS $(\mathcal{S}, \mathcal{C}, \mathcal{R}, \mathcal{K})$ with $\dim \mathcal{J} = 1$, let a scalar function $g(x, u)$ defined on $\mathbb{R}_{>0}^n \times \mathbb{R}_{>0}$ be

$$
g(x, u) = \sum_{\{i|m_i>0\}} (k_i x^{v_i}) \left( \sum_{j=0}^{m_i-1} u^j \right) + \sum_{\{i|m_i<0\}} (k_i x^{v_i}) \left( - \sum_{j=m_i} u^j \right).
$$

If the MAS admits a positive steady state $x^* \in \mathbb{R}_{>0}^n$, then there exists a unique $\tilde{u} \in \mathcal{C}^2$ such that $g(x, \tilde{u}(x)) = 0$.

**Proof.** Since the MAS admits a positive steady state $x^*$, its dynamics satisfies

$$
\dot{x}|_{x=x^*} = \sum_{i=1}^r k_i (x^*)^{v_i} (v_i' - v_i)
$$

$$
= \sum_{\{i|m_i>0\}} k_i (x^*)^{v_i} (m_i) - \sum_{\{i|m_i<0\}} k_i (x^*)^{v_i} (m_i) = 0,
$$

which indicates that neither $\{i|m_i > 0\}$ nor $\{i|m_i < 0\}$ is an empty set. Combing this fact and the definition (27) of $g(x, u)$ yields that $g(x, u)$ is continuous in $\mathbb{R}_{>0}^n \times \mathbb{R}_{>0}$, and moreover for $\forall x \in \mathbb{R}_{>0}^n$, $g(x, u)$ is continuous differentiable about $u$ with

$$
\frac{\partial}{\partial u} g(x, u) = \sum_{\{i|m_i>0\}} (k_i x^{v_i}) \left( \sum_{j=1}^{m_i-1} j u^{j-1} \right) + \sum_{\{i|m_i<0\}} (k_i x^{v_i}) \left( - \sum_{j=m_i} u^{j-1} \right) > 0.
$$

Hence, $g(x, u)$ is monotone increasing over $u$. Also, note the facts that

$$
\lim_{u \to 0} g(x, u) = -\infty \quad \text{and} \quad \lim_{u \to +\infty} g(x, u) = +\infty,
$$

then based on the intermediate value theorem there exists a unique $\tilde{u}(x) \in \mathbb{R}_{>0}$ such that $g(x, \tilde{u}(x)) = 0$. In addition, $g(x, u)$ is also continuously differentiable about $x$ and $g_u(x, u)|_{u=\tilde{u}} \neq 0$, so we have $\tilde{u} \in \mathcal{C}^1(\mathbb{R}_{>0}^n; \mathbb{R}_{>0})$ according to the implicit function theorem and $\nabla \tilde{u}(x) = -g_x(x, \tilde{u}(x))/g_u(x, \tilde{u}(x))$. Moreover, since the functions $g_x$ and $g_u$ are also continuously differentiable with respect to both parameters, the function $\nabla \tilde{u}(x)$ is also continuously differentiable and therefore $\tilde{u} \in \mathcal{C}^2(\mathbb{R}_{>0}^n; \mathbb{R}_{>0})$, which completes the proof.

Based on the function $\tilde{u}(x)$, we could find a solution for the Lyapunov function PDEs (24) plus (25) derived from a MAS with $\dim \mathcal{J} = 1$ and a positive equilibrium. For this purpose, we begin with the following two lemmas.
Lemma 16. For a MAS $(S,C,R,K)$ with $\dim \mathcal{S} = 1$, let $w \in \mathbb{R}^n \setminus \{0_n\}$ be a set of bases of $\mathcal{S}$, and $\bar{x} \in \mathbb{R}_{>0}^n$ represent any boundary point of any positive stoichiometric compatibility class induced by $\mathcal{S}$. Denote the index sets of positive and negative entries of $w$ by $P_w$ and $N_w$, respectively, and the index set of zero entries of $\bar{x}$ by $Z_{\bar{x}}$, then for $\forall \bar{x}$, 

$$Z_{\bar{x}} \subseteq P_w \text{ or } Z_{\bar{x}} \subseteq N_w.$$ 

Proof. Since $\bar{x}$ is a boundary point of a positive stoichiometric compatibility class induced by $\mathcal{S}$, so there exists a nonzero constant $\alpha \in \mathbb{R}$ such that 

$$\bar{x} + \alpha w \in \mathbb{R}_{>0}^n.$$ 

If $\alpha > 0$, then for $\forall i \in Z_{\bar{x}}$ ($Z_{\bar{x}}$ is obviously non-empty) we have 

$$\bar{x}_i + \alpha w_i > 0 \Rightarrow w_i > 0 \Rightarrow i \in P_w.$$ 

Therefore, $Z_{\bar{x}} \subseteq P_w$. Similarly, if $\alpha < 0$ then we get $Z_{\bar{x}} \subseteq N_w$. 

Lemma 17. For a MAS $(S,C,R,K)$ with $\dim \mathcal{S} = 1$, a function $J(y)$ from positive stoichiometric compatibility class $(x + \mathcal{S}) \cap \mathbb{R}_{>0}^n$ to $\mathbb{R}$ is defined as follows 

$$(28) \quad J(y) = \begin{cases} \prod_{i \in P_w} y_i - \prod_{i \in N_w} y_i, & P_w, N_w \neq \emptyset, \\ \prod_{i \in P_w} y_i - 1, & P_w \neq \emptyset, N_w = \emptyset, \\ \prod_{i \in N_w} y_i - 1, & N_w \neq \emptyset, P_w = \emptyset, \\ \end{cases}$$

where $x \in \mathbb{R}_{>0}^n$ represents any state of the MAS. Then, this function $J(y)$ admits a unique zero point in every $(x + \mathcal{S}) \cap \mathbb{R}_{>0}^n$, and moreover, the unique zero point is a twice continuous differential function with respect to $x$, denoted by $y^{\dagger} \in \mathcal{C}^2(\mathbb{R}_{>0}^n; \mathbb{R})$. In addition, there also exists another twice continuous differential function $\gamma \in \mathcal{C}^2(\mathbb{R}_{>0}^n; \mathbb{R})$, which together with $y^{\dagger}(x)$ satisfies 

$$x = y^{\dagger}(x) + \gamma(x)w \text{ and } \gamma(x + \delta w) = \gamma(x) + \delta, \forall \delta \in \mathbb{R},$$

where $w$ is a set of bases of $\mathcal{S}$.

Proof. Clearly, for $\forall y \in (x + \mathcal{S}) \cap \mathbb{R}_{>0}^n$ there exists a boundary point $\bar{x}$ and $\beta \in \mathbb{R}$, $\beta \neq 0$ such that $y = \bar{x} + \beta w$. We conduct the proof according to three different cases below:

1) $P_w \neq \emptyset$ and $N_w \neq \emptyset$. In every $(x + \mathcal{S}) \cap \mathbb{R}_{>0}^n$, there may exist two distinct boundary points, denoted by $\bar{x}$ and $\bar{x}'$, and moreover, they could reach each other through $\bar{x}' = \bar{x} + \beta_M w$, where $\beta_M \in \mathbb{R}$ but $\beta_M \neq 0$. According to Lemma 16, for $\bar{x}$ either $Z_{\bar{x}} \subseteq P_w$ or $Z_{\bar{x}} \subseteq N_w$ is true. If $Z_{\bar{x}} \subseteq P_w$, then we have $\beta_M > 0$ and $\beta \in (0, \beta_M)$. Further, we have $Z_{\bar{x}'} \subset N_w$. Following these results, we get 

$$\lim_{\beta \to 0} J(\bar{x} + \beta w) < 0 \text{ and } \lim_{\beta \to \beta_M} J(\bar{x} + \beta w) > 0.$$ 

By the intermediate value theorem, there exist a point $y^{\dagger} \in (x + \mathcal{S}) \cap \mathbb{R}_{>0}^n$ rendering $J(y^{\dagger}) = 0$. Also, we note that $\frac{d}{dt} J(\bar{x} + \beta w) = \left( \frac{\partial J}{\partial y} \right)^\top \frac{\partial y}{\partial \beta} > 0$, the zero point $y^{\dagger}$ is unique. Similarly, if $Z_{\bar{x}} \subseteq N_w$, the result is true too.
2) $P_w \neq \emptyset$ and $N_w = \emptyset$. In this case $Z_\delta \subseteq P_w$ and $\alpha \in (0, +\infty)$. Thus, we have

$$\lim_{\beta \to 0} J(\bar{x} + \beta w) = -1, \quad \lim_{\beta \to +\infty} J(\bar{x} + \beta w) = +\infty \quad \text{and} \quad \frac{d}{d\beta} J(\bar{x} + \beta w) > 0.$$ 

According to the intermediate value theorem and strict monotonicity, $J(y)$ admits a unique zero point in $(x + \mathcal{S}) \cap \mathbb{R}_{>0}^n$.

3) $N_w \neq \emptyset$ and $P_w = \emptyset$. Based on the similar reason as in case 2), we can get the result immediately.

We continue to prove $y^\dagger \in C^2(\mathbb{R}_{>0}^n; \mathbb{R}_{>0}^n)$ and $\gamma \in C^2(\mathbb{R}_{>0}^n; \mathbb{R})$. Let the function

$$\tilde{J}(x, \beta) = J(x - \beta w), \quad x - \beta w \in \mathbb{R}_{>0}^n.$$ 

Clearly, for $\forall x \in \mathbb{R}_{>0}^n$ there exists a sole $\beta = \gamma(x)$ such that $J(x - \gamma(x)w) = 0$, i.e., $x - \gamma(x)w = y^\dagger(x)$ and $J(x, \gamma(x)) = 0$. Note that $J(x, \beta)$ is continuous differentiable from the definition of $J(y)$ and $\frac{\partial}{\partial \beta} \tilde{J}(x, \beta)_{\beta=\gamma(x)} \neq 0$, then by the implicit function theorem we have $\gamma \in C^1(\mathbb{R}_{>0}^n; \mathbb{R})$ and $\nabla \gamma(x) = -\tilde{J}_x(x, \gamma(x)) / \tilde{J}_\beta(x, \gamma(x))$. In addition, since the function $\tilde{J}_x$ and $\tilde{J}_\beta$ are also continuous differentiable with respect to both parameters, we can conclude that $\nabla \gamma(x)$ is continuous differentiable and therefore $\gamma \in C^2(\mathbb{R}_{>0}^n; \mathbb{R})$. Further, we get $y^\dagger \in C^2(\mathbb{R}_{>0}^n; \mathbb{R}_{>0}^n)$ from $y^\dagger(x) = x - \gamma(x)w$, i.e., $x = y^\dagger(x) + \gamma(x)w$.

Finally, we focus on proving $\gamma(x + \delta w) = \gamma(x) + \delta, \quad \forall \delta \in \mathbb{R}$. Since $(x + \mathcal{S}) \cap \mathbb{R}_{>0}^n = (x + \delta w + \mathcal{S}) \cap \mathbb{R}_{>0}^n$, we have $y^\dagger(x) = y^\dagger(x + \delta w)$, i.e., $x + \delta w - \gamma(x + \delta w)w = x - \gamma(x)w$. Further, since $w$ is a set of bases of $\mathcal{S}$, we get $\gamma(x + \delta w) = \gamma(x) + \delta, \quad \forall \delta$.

By means of $\tilde{u}(x)$, $y^\dagger(x)$ and $\gamma(x)$, a solution for the Lyapunov function PDEs (24) plus (25) is reachable.

**Theorem 18.** For a MAS $(\mathcal{S}, \mathcal{C}, \mathcal{R}, \mathcal{K})$ with $\dim \mathcal{S} = 1$ and a positive steady state, $\mathcal{C}_\bar{x}$ in the form of (20) is selected as the boundary complex set where $\bar{x}$ is any boundary point of any positive stoichiometric compatibility class induced by $\mathcal{S}$. Assume that $\mathcal{C}_\bar{x} = \emptyset$ or $\mathcal{C}_\bar{x}$ includes at least a reactant complex and a resultant complex, then the function defined by

$$f(x) = \int_0^{\gamma(x)} \ln \tilde{u}(y^\dagger(x) + \tau w) d\tau$$

is a solution of the Lyapunov function PDEs (24) plus (25), where $y^\dagger(x)$, $\gamma(x)$ and $w$ share the same meanings with those in Lemma 17.

**Proof.** (1) The first part serves for proving that $f(x)$ in the form of (29) satisfies (24). Since $y^\dagger, \gamma, \tilde{u} \in C^2$, $f(x)$ is obviously a twice continuous differentiable function defined on
\[ \mathbb{R}^n_{>0}. \text{ Thus, we have} \]
\[
w^T \nabla f(x) = \lim_{\delta \to 0} \frac{f(x + \delta w) - f(x)}{\delta}
\]
\[
= \lim_{\delta \to 0} \frac{1}{\delta} \int_{\gamma(x)}^{\gamma(x+\delta)} \ln \tilde{u}(y^t(x) + \tau w) d\tau
\]
\[
= \lim_{\delta \to 0} \frac{1}{\delta} \int_{\gamma(x)}^{\gamma(x)+\delta} \ln \tilde{u}(y^t(x) + \tau w) d\tau
\]
\[
= \ln \tilde{u}(y^t(x) + \gamma(x)w).
\]

Namely, \( \exp\{w^T \nabla f(x)\} = \tilde{u}(y^t(x) + \gamma(x)w) = \tilde{u}(x) \), which obviously satisfies (24).

(2) The second part contributes to verifying that the current \( f(x) \) satisfies the boundary condition of (25). We address this issue according to two different cases.

\textbf{Case I:} \( C_\bar{x} = \emptyset \). In this case (25) is obviously true since it is \( “0 = 0” \).

\textbf{Case II:} \( C_\bar{x} \neq \emptyset \). In this case there include at least two complexes in \( C_\bar{x} \), one acting as a reactant complex and the other as a resultant complex. According to the definition of \( C_\bar{x} \) in (20), we have \( v_{ji} = 0 \) and \( v'_{ji} = 0 \) for \( \forall \ j \in Z_\bar{x} \) if \( v_i, v'_i \in C_\bar{x} \). Note that \( i = i' \) is possible. Further, from Lemma 16 we get \( Z_\bar{x} \subseteq P_w \) or \( Z_\bar{x} \subseteq N_w \). For simplicity, let \( Z_\bar{x} \subseteq P_w \) for the following proof.

Imitating the boundary condition of (25), for \( \forall \ \bar{x} \) we define a function \( h(x, a) \) from \( (\bar{x}) \cup (x + \mathcal{S}) \cap \mathbb{R}^n_{>0} \times \mathbb{R}_{>0} \) to \( \mathbb{R} \) as

\[
h(x, a) = \sum_{\{i|v_i \in \bar{C}_x\}} k_i x^{v_i} - \sum_{\{i|v'_i \in \bar{C}_x\}} k_i x^{v_i+\bar{w}_i} a^{m_i},
\]

where \( \bar{w} \in \mathbb{R}^n \) with the \( j \)th \( (j = 1, \cdots, n) \) entry satisfying \( \bar{w}_j = w_j \) if \( j \in Z_\bar{x} \), and \( \bar{w}_j = 0 \) otherwise, and \( m_i \) shares the same meaning with (26). For the first term in the right hand side, since for \( \forall \ j \in Z_\bar{x}, v_{ji} = 0 \), we have \( \bar{x}^{v_i} > 0 \). We further analyze the sign of \( x^{v_i+\bar{w}_i} \) in the second term. At this time \( v'_i \in \bar{C}_x \), we thus have \( v'_{ji} = 0 \) for \( \forall \ j \in Z_\bar{x} \), where \( v'_{ji} = v_{ji} + m_i \bar{w}_j \) (based on (26)) = \( v_{ji} + m_i \bar{w}_j = 0 \). This means \( x^{v_i+\bar{w}_i} > 0 \) and \( m_i < 0 \) \( (j \in Z_\bar{x} \subseteq P_w, \bar{w}_j > 0 \) and \( v_{ji} > 0 \)) in the second term. Based on these facts, we get

\[
\lim_{a \to 0} h(x, a) = -\infty, \quad \lim_{a \to +\infty} h(x, a) > 0 \quad \text{and} \quad \frac{\partial}{\partial a} h(x, a) > 0.
\]

As a result, there must exist a unique positive function \( \hat{a}(x) \) such that \( h(x, \hat{a}(x)) = 0 \) for \( \forall \ x \) by the intermediate value theorem and monotonicity. Further, the function \( \hat{a}(x) \) is continuous differentiable by the implicit function theorem.

Based on \( h(x, a) \) we further define another continuous differentiable function \( \tilde{h}(x, a) \) from \( ((x + \mathcal{S}) \cap \mathbb{R}^n_{>0}) \times \mathbb{R}_{>0} \) to \( \mathbb{R} \) as

\[
\tilde{h}(x, a) = h(x, a) + \sum_{\{i|v_i \notin \bar{C}_x\}} k_i x^{v_i} - \sum_{\{i|v'_i \notin \bar{C}_x\}} k_i x^{v_i+\bar{w}_i} a^{m_i}.
\]

For the second term in the right hand side, when \( v_i \notin \bar{C}_x \) there exists \( j \in Z_\bar{x} \) such that \( \bar{x}_j = 0 \) and \( v_{ji} > 0 \), i.e., \( \bar{x}^{v_i} = 0 \). Analogously, for the third term when \( v'_i \notin \bar{C}_x \) there also exists
\( j \in \mathbb{Z}_2 \) such that \( \bar{x}_j = 0 \) and \( v'_j = v_j + m_i w_j = v_j + m_i \bar{w}_j > 0 \), i.e., \( \bar{x}^{v_i + m_i \bar{w}} = 0 \). Hence, for \( \forall x \in (\bar{x} + \mathcal{S}) \cap \mathbb{R}_{>0}^n \) we get

\[
\lim_{x \to \bar{x}} \sum_{\{i | v_i \notin C_x \}} k_i x^{v_i} = 0 \quad \text{and} \quad \lim_{x \to \bar{x}} \sum_{\{i | v'_i \notin C_x \}} k_i x^{v_i + m_i \bar{w}} = 0.
\]

Further we have

\[
\lim_{x \to \bar{x}} \frac{\partial^2}{\partial a \partial a} \hat{h}(x, \hat{a}(x)) = \frac{\partial}{\partial a} h(x, \hat{a}(x)) \bigg|_{x = \bar{x}} > 0,
\]

which means \( \frac{\partial}{\partial a} \hat{h}(x, \hat{a}(x)) > 0 \) in \( \mathcal{E}_1(\bar{x}) \), a certain neighborhood of \( \bar{x} \). Based on the same analysis, we can obtain \( \frac{\partial^2}{\partial a \partial a} \hat{h}(x, a) \leq 0 \) in another certain neighborhood of \( \bar{x} \), denoted by \( \mathcal{E}_2(\bar{x}) \).

Suppose \( v'_p \in C_\bar{x} \) and consider the neighborhood of \( \bar{x} \), \( \mathcal{E}_1(\bar{x}) \cap \mathcal{E}_2(\bar{x}) \), within which let

\[
\theta_1(x) = - \left( \sum_{\{i | v_i \notin C_x \}} k_i x^{v_i} - \sum_{\{i | v'_i \notin C_x \}} k_i x^{v_i + m_i \bar{w}} \hat{a}(x)^{m_i} \right) \left/ \frac{\partial \hat{h}(x, a)}{\partial a} \right|_{a = \hat{a}(x)}
\]

and

\[
\theta_2(x) = \frac{\sum_{\{i | v'_i \notin C_x \}} \left( \sum_{m_i > 0} k_i x^{v_i + m_i \bar{w}} \hat{a}(x)^{m_i} + \sum_{m_i < 0} k_i x^{v_i + m_i \bar{w}} \left[ \frac{1}{2} \hat{a}(x) \right]^{m_i} \right)}{k_p x^{v_p + m_p \bar{w}} \hat{a}(x)^{m_p}},
\]

then we get

\[
\hat{h}(x, \hat{a}(x) + \theta_1(x)) \leq \hat{h}(x, \hat{a}(x)) + \frac{\partial \hat{h}(x, a)}{\partial a} \bigg|_{a = \hat{a}(x)} \theta_1(x) = h(x, \hat{a}(x)) = 0.
\]

Further let

\[
\theta_3(x) = \max \left\{ 1, \left| 1 - \sum_{\{i | v_i \notin C_x \}} k_i x^{v_i} \right/ k_p x^{v_p + m_p \bar{w}} \hat{a}(x)^{m_p} + \theta_2(x) \right| ^{\frac{1}{n_p}} \right\}.
\]

It is easy to verify that \( \lim_{x \to \bar{x}} \theta_3(x) = 1 \), from which we also obtain \( 1 < \theta_3(x) < 2 \) when \( x \) is in a certain neighborhood of \( \bar{x} \), \( \mathcal{E}_3(\bar{x}) \). Hence, for \( \forall x \in \{ \mathcal{E}_1(\bar{x}) \cap \mathcal{E}_2(\bar{x}) \cap \mathcal{E}_3(\bar{x}) \} \) we have

\[
h(x, \theta_3(x) \hat{a}(x)) > h(x, \hat{a}(x)), \quad 0 > k_p x^{v_p + m_p \bar{w}} \left( \theta_3(x) \hat{a}(x) \right)^{m_p} - k_p x^{v_p + m_p \bar{w}} \hat{a}(x)^{m_p}
\]

and

\[
\sum_{\{i | v_i \notin C_x \}} k_i x^{v_i} - \sum_{\{i | v'_i \notin C_x \}} k_i x^{v_i + m_i \bar{w}} \left( \theta_3(x) \hat{a}(x) \right)^{m_i} > \sum_{\{i | v_i \notin C_x \}} k_i x^{v_i} - \sum_{\{i | v'_i \notin C_x \}} k_i x^{v_i + m_i \bar{w}} \left( \frac{1}{2} \hat{a}(x) \right)^{m_i}.
\]

Note that the sum of the left terms of these three inequalities is just expressed as

\[
\hat{h}(x, \theta_3(x) \hat{a}(x)) = h(x, \theta_3(x) \hat{a}(x)) + \sum_{\{i | v_i \notin C_x \}} k_i x^{v_i} - \sum_{\{i | v'_i \notin C_x \}} k_i x^{v_i + m_i \bar{w}} \left( \theta_3(x) \hat{a}(x) \right)^{m_i}
\]
Therefore, there must exist a solution between \( \hat{a}(x) + \theta_1(x) \) and \( \theta_3(x) \hat{a}(x) \), denoted by \( \tilde{a}(x) \), such that \( \tilde{h}(x, \theta_3(x) \tilde{a}(x)) = 0 \), i.e.,

\[
\tilde{h}(x, \theta_3(x) \tilde{a}(x)) + \sum_{i: | i' | \notin \mathcal{C}_x} k_i x^{v_i} - \sum_{i: | i' | \notin \mathcal{C}_x} k_i x^{v_i+m_i} \tilde{w}(\tilde{a}(x))^{m_i} = 0.
\]

This together with the definition of \( \tilde{h}(x, a) \) evaluated at \( a = \tilde{a}(x) \) leads to

\[
\sum_{i=1}^r k_i x^{v_i} - \sum_{i=1}^r k_i x^{v_i+m_i} \tilde{w}(\tilde{a}(x))^{m_i} = 0.
\]

Comparing it to the Lyapunov PDE of (24) yields that \( u(x) = x^{\tilde{w}} \tilde{a}(x) \) is a solution of \((u - 1)g(x, u) = 0 \). Note the facts that

\[
\lim_{x \to \bar{x}} \tilde{a}(x) = \hat{a}(\bar{x}) \quad \text{and} \quad \lim_{x \to \bar{x}} x^{\tilde{w}} \tilde{a}(x) = 0.
\]

Further, there exists a certain neighborhood of \( \bar{x} \), \( \mathcal{E}_4(\bar{x}) \), such that \( x^{\tilde{w}} \tilde{a}(x) \neq 1 \). Hence, if \( x \in \mathcal{E}_1(\bar{x}) \cap \mathcal{E}_2(\bar{x}) \cap \mathcal{E}_3(\bar{x}) \cap \mathcal{E}_4(\bar{x}) \), we have \( g(x, x^{\tilde{w}} \tilde{a}(x)) = 0 \), i.e., \( \tilde{u}(x) = x^{\tilde{w}} \tilde{a}(x) \).

Utilizing the above analysis, we get

\[
\text{L.H.S of Eq. (25)} = \lim_{\substack{x \to \bar{x} \\in \mathcal{E}_4(\bar{x}) \cap \mathbb{R}^n_{>0}}} h(x, \tilde{a}(x)) = h(\bar{x}, \tilde{a}(\bar{x})) = 0.
\]

Therefore, \( f(x) \) in the form of (29) satisfies the boundary condition of (25).

Similarly, in the case of \( Z_x \subseteq N_w \) the results hold too, which completes the proof. \( \blacksquare \)

The following task focuses on verifying if \( f(x) = \int_0^{\gamma(x)} \ln \tilde{u}(y^\dagger(x) + \tau \bar{w}) \mathrm{d}\tau \) is able to serve as an Lyapunov function for MASs with \( \text{dim} \mathcal{F} = 1 \).

**Theorem 19.** For a MAS \((\mathcal{S}, \mathcal{C}, \mathcal{R}, \mathcal{K})\) with \( \text{dim} \mathcal{F} = 1 \) and a positive steady state \( x^* \in \mathbb{R}^n_{>0} \), let \( \mathcal{C}_x \) defined by (20) represent the boundary complex set where \( \bar{x} \) is any boundary point of any positive stoichiometric compatibility class induced by \( \mathcal{F} \). If

- \( \mathcal{C}_x = \emptyset \) or \( \mathcal{C}_x \) includes at least a reactant complex and a resultant complex;
- \( w^T \frac{\partial}{\partial x} g(x^*, 1) < 0 \) with \( g(x, u) \) defined by (27),

then the Lyapunov Function PDEs (24) and (25) are qualified to generate a Lyapunov function (29) to render this MAS to be locally asymptotically stable at \( x^* \).
Proof. Since \( g(x, u) \) and \( \tilde{u}(x) \) are continuous and \( \tilde{u}(x^*) = e^{w^\top \nabla f(x^*)} = 1 \), by the second condition listed in the theorem, there is a neighborhood of \( x^* \), denoted as \( \delta(x^*) \), such that \( \forall x \in \delta(x^*) \) we have

\[
(30) \quad w^\top \frac{\partial}{\partial x} g(x, \tilde{u}(x)) < 0.
\]

Moreover, for the function \( f(x) \) given in (29), since \( w^\top \nabla f(x) = \ln \tilde{u}(x) \), we have

\[
\nabla^2 f(x) w = \frac{\nabla \tilde{u}(x)}{\tilde{u}(x)}.
\]

Therefore, \( \forall x \in \delta(x^*) \) and \( \forall \mu \in \mathcal{S} \) there is

\[
\mu^\top \nabla^2 f(x) \mu = (\mu^\top w)^2 \cdot \frac{\nabla \tilde{u}(x)}{\tilde{u}(x)}
= (\mu^\top w)^2 \cdot \frac{\nabla \tilde{u}(x)}{\tilde{u}(x)}
= (\mu^\top w)^2 \cdot \frac{-w^\top \frac{\partial}{\partial x} g(x, \tilde{u}) / \frac{\partial}{\partial u} g(x, \tilde{u})}{\tilde{u}(x)}
\geq 0,
\]

where the last inequality follows from (30) and the equality holds if and only if \( \mu = 0_n \). Thus the condition (22) is satisfied. *Theorem 18* has shown that the function (29) is a solution of the PDEs, therefore the result holds immediately from *Theorem 10*.

*Remark 4.* The condition \( w^\top \frac{\partial}{\partial x} g(x^*, 1) < 0 \) essentially characterizes some behaviors of the MAS system after linearization. From the dynamic equation (9) in the case of \( \text{dim} \mathcal{S} = 1 \)

\[
\dot{x}(t) = \sum_{i=1}^{r} k_i x^{v_i} (v'_i - v_i) = \sum_{i=1}^{r} k_i x^{v_i} m_i w,
\]

we get the linearized form at \( x = x^* \) as

\[
\dot{x}(t) = w \left( \frac{\partial g(x^*, 1)}{\partial x} \right)^\top (x - x^*).
\]

It is clear that the coefficient matrix \( w \left( \frac{\partial g(x^*, 1)}{\partial x} \right)^\top \) is of rank one and thus has only two eigenvalues \( w^\top \frac{\partial}{\partial x} g(x^*, 1) \) plus 0 if \( n \neq 1 \). Therefore, the condition \( w^\top \frac{\partial}{\partial x} g(x^*, 1) < 0 \) means that the coefficient matrix need have a negative eigenvalue, which, namely, requests the linearized system of the MAS to be necessarily stable (but not necessarily asymptotically stable unless \( n = 1 \)) at \( x = x^* \).

Another point should be noted that the solution (29) of the Lyapunov Function PDEs has the similar form with the Lyapunov function constructed in Anderson and his coworkers’ paper for Birth-Death processes [2]. Both functions are established by integrating a logarithmic
function. The possible reasons are that the birth-death process studied in [2] is also a 1-dimensional CRN, and that the Lyapunov function PDEs and the scaling limit of the non-equilibrium potential have the same origin. This phenomenon conversely implies that the PDEs can work for Birth-Death processes.

We further demonstrate the efficiency of Lyapunov Function PDEs for CRNs with \( \dim \mathcal{S} = 1 \) through two examples.

**Example 2.** For the MAS

\[
S_1 \xrightarrow{k_1} S_2, \quad 2S_2 \xrightarrow{k_2} 2S_1,
\]

we have the species set \( \mathcal{S} = \{S_1, S_2\} \), the complex set \( \mathcal{C} = \{v_1, v_1', v_2, v_2'\} \), the reaction set \( \mathcal{R} = \{v_1 \rightarrow v_1', v_2 \rightarrow v_2'\} \), and the kinetics set \( \mathcal{K} = (k_1, k_2) \), where

\[
v_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad v_1' = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad v_2 = \begin{pmatrix} 0 \\ 2 \end{pmatrix}, \quad v_2' = \begin{pmatrix} 2 \\ 0 \end{pmatrix}, \quad \dim \mathcal{S} = 1.
\]

By the mass-action kinetics, the dynamics of the system is expressed as

\[
\begin{align*}
\dot{x}_1(t) &= -k_1 x_1 + 2k_2 x_2^2, \\
\dot{x}_2(t) &= k_1 x_1 - 2k_2 x_2^2.
\end{align*}
\]

By choosing \( w = (-1, 1)^\top \) as the basis for \( \mathcal{S} \), we can write the Lyapunov Function PDEs in the form of (24) where \( m_1 = 1 \) and \( m_2 = -2 \). Moreover, from Proposition 15 we have

\[
P_w = \{2\}, \quad N_w = \{1\} \quad \text{and} \quad g(x, u) = k_1 x_1 - k_2 x_2^2 u^{-1} - k_2 x_2^2 u^{-2}.
\]

Furthermore, utilizing Lemma 17 and setting \( g(x, u) = 0 \) we get auxiliary functions

\[
y^\dagger(x) = \frac{1}{2} \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \quad \gamma(x) = \frac{w^\top x}{2} \quad \text{and} \quad \tilde{u}(x) = \frac{k_2 x_2^2 + x_2 \sqrt{k_1^2 x_2^4 + 4k_2 k_1 x_1}}{2k_1 x_1}.
\]

For the considered MAS, there include two types of boundary points, one type of points are \( \bar{x} = (\bar{x}_1, 0)^\top \) with \( \bar{x}_1 > 0 \), the other type of points are \( \bar{x} = (0, \bar{x}_2)^\top \) with \( \bar{x}_2 > 0 \). Following the definition of \( C_{\bar{x}} \) in (20), we set

\[
C_{\bar{x}} = \left\{ \begin{array}{ll}
\{v_1, v_1'\}, & \bar{x} = (\bar{x}_1, 0)^\top \text{ with } \bar{x}_1 > 0; \\
\{v_2, v_2'\}, & \bar{x} = (0, \bar{x}_2)^\top \text{ with } \bar{x}_2 > 0.
\end{array} \right.
\]

Finally, we obtain a solution, based on Theorem 18, as

\[
f(x) = \int_0^{\gamma(x)} \ln \frac{k_2 [y^\dagger(x) + \tau u]^v + \sqrt{k_1^2 [y^\dagger(x) + \tau u]^{2v} + 4k_1 k_2 [y^\dagger(x) + \tau u]^{v+1} + 2}}{2k_1 [y^\dagger(x) + \tau u]^{v+1}} \, d\tau
\]

for the Lyapunov Function PDEs (24) plus (25).

Let \( x^* \in \mathbb{R}^2_{>0} \) be an equilibrium in \( (x^* + \mathcal{S}) \cap \mathbb{R}^2_{>0} \). According to Theorem 19, since \( w^\top \frac{\partial g(x^*, 1)}{\partial x} = -k_1 - 4k_2 x^*_2 < 0 \), the current \( f(x) \) is an available Lyapunov function for suggesting the studied system to be locally asymptotically stable at \( x^* \).
Note that the condition \( w^\top \partial g(x^*,1) = -k_1 - 4k_2x^* \lg 0 \) in Example 2 is always true, which in turn means it reasonable to set the condition of \( w^\top \partial g(x^*,1) \lg 0 \) in Theorem 19.

Example 3. This 1-dimensional MAS only contains a single species \( S_1 \) and has a reversible reaction structure, given by

\[
0 \xrightleftharpoons[k_2][k_1] S_1, \quad 2S_1 \xrightleftharpoons[k_3][k_4] 3S_1.
\]

Denote \( R_i \) by the reaction with the rate coefficient \( k_i, i = 1, \cdots, 4 \), then \( v_1 = v'_2 = 0, v_2 = v'_1 = 1, v_3 = v'_4 = 2, \) and \( v_4 = v'_3 = 3 \). Further by setting \( k_1 = k_4 = 2 \) and \( k_2 = k_3 = 1 \), the dynamics of this MAS is written as

\[
\dot{x}_1(t) = 2 - x_1 + x_1^2 - 2x_1^3.
\]

Clearly, the system admits a unique equilibrium point \( x_1^* = 1 \). Note that this equilibrium is not complex balanced since at it the zero complex does not balance between the reaction rate 2 and the production rate 1. The pseudo-Helmholtz free energy function is thus not an appropriate Lyapunov function for stability analysis. Instead, we use the current Lyapunov Function PDEs for stability analysis.

We set \( w = 1 \) as the base for the stoichiometric subspace, then \( m_1 = m_3 = 1, m_2 = m_4 = -1 \) and \( g(x,u) = 2 + x^2 - \frac{1}{u}(x + 2x^3) \). Further, we get

\[
y^1(x) = 1, \quad \gamma(x) = x - 1, \quad \hat{u}(x) = \frac{x + 2x^3}{2 + x^2} \quad \text{and} \quad \mathcal{C}_x = \{0\}.
\]

Finally, based on on Theorem 18, the solution for the Lyapunov Function PDEs (24) plus (25) is expressed as

\[
f(x) = \int_0^{x-1} \ln \left( \frac{1 + \tau + 2(1 + \tau)^3}{2 + (1 + \tau)^2} \right) d\tau.
\]

Since \( w^\top \partial g(x^*,1) = 2x^* - 1 - 6(x^*)^2 = -5 \leq 0 \), the above function \( f(x) \) is a valid Lyapunov function for suggesting the studied system to be locally asymptotically stable at \( x^* = 1 \).

6. Lyapunov Function PDEs for some CRNs with \( \dim \mathcal{S} \geq 2 \). For general CRNs with \( \dim \mathcal{S} \geq 2 \), we are not able to prove that the Lyapunov Function PDEs (15) plus (19) work validly in this paper. However, they are shown valid for some special CRNs with \( \dim \mathcal{S} \geq 2 \).

6.1. CRNs of \( \dim \mathcal{S} \geq 2 \) Composed of a Complex Balanced CRN and a series of CRNs of \( \dim \mathcal{S} = 1 \). Consider a MAS \((\mathcal{S}, \mathcal{C}, \mathcal{R}, \mathcal{K})\) as a combination of a complex balanced MAS, labeled as \((\mathcal{S}^{(0)}, \mathcal{C}^{(0)}, \mathcal{R}^{(0)}, \mathcal{K}^{(0)})\), and a few MASs of 1-dimensional stoichiometric subspace, denoted by \((\mathcal{S}^{(p)}, \mathcal{C}^{(p)}, \mathcal{R}^{(p)}, \mathcal{K}^{(p)})\) \((p = 1, \cdots, \ell)\), respectively. These sub-networks are assumed to be independent each other. Namely, for \( \forall p, q \in \{0, \cdots, \ell\}, \) if \( p \neq q \), then \( \mathcal{S}^{(p)} \cap \mathcal{S}^{(q)} = \emptyset \). We define this class of CRNs as “Com-\( \ell \)Sub1” CRNs, and the corresponding MASs are named “Com-\( \ell \)Sub1” MASs.

In every sub-network \((\mathcal{S}^{(p)}, \mathcal{C}^{(p)}, \mathcal{R}^{(p)})\), let \( n_p, r_p \) represent the number of species and of reactions, \( v_i(p) \) the reactant complex and \( v'_i(p) \) the resultant complex of the \( i \)th reaction.

24
(\(i = 1, \ldots, r_p\)), respectively. Also, denote
\[
n = \sum_{p=0}^{\ell} n_p, \quad v^{(p)} = \bigotimes_{q=0}^{p-1} \mathcal{O}_{n_q} \bigotimes_{q=p+1}^{\ell} \mathcal{O}_{n_q} \quad \text{and} \quad v^{(p)} = \bigotimes_{q=0}^{p-1} \mathcal{O}_{n_q} \bigotimes_{q=p+1}^{\ell} \mathcal{O}_{n_q},
\]
where \(\bigotimes\) is the Cartesian product, and \(n_q = 0\) if \(q < 0\) or \(q > \ell\), then the MAS \((\mathcal{S}, \mathcal{C}, \mathcal{R}, \mathcal{K})\) under consideration is expressed as
\[
\mathcal{S} = \bigcup_{p=0}^{\ell} \mathcal{S}^{(p)}, \quad \mathcal{C} = \bigcup_{p=0}^{\ell} \bigcup_{i=1}^{r_p} \{v^{(p)}_i, v^{(p)}_i\} \quad \text{and} \quad \mathcal{R} = \bigcup_{p=0}^{\ell} \bigcup_{i=1}^{r_p} \{v^{(p)}_i \xrightarrow{k^{(p)}_i} v^{(p)}_i\}
\]
with the dynamics to be
\[
\dot{x} = \sum_{p=0}^{\ell} \sum_{i=1}^{r_p} k^{(p)}_i x^{(p)}_i \left( v^{(p)}_i - v^{(p)}_i \right),
\]
where the state \(x = \bigotimes_{p=0}^{\ell} x^{(p)} \in \mathbb{R}_{\geq 0}^{n} \) and \(x^{(p)} \in \mathbb{R}_{\geq 0}^{n}\) is the state of the mass action system \(\{\mathcal{S}^{(p)}, \mathcal{C}^{(p)}, \mathcal{R}^{(p)}, \mathcal{K}^{(p)}\}\). Note that for \(\forall \ p, q \in \{0, \ldots, \ell\} \) if \(p \neq q\) then
\[
\left\{ \bigcup_{i=1}^{r_p} \{v^{(p)}_i \xrightarrow{k^{(p)}_i} v^{(p)}_i\} \right\} \cap \left\{ \bigcup_{i=1}^{r_q} \{v^{(q)}_i \xrightarrow{k^{(q)}_i} v^{(q)}_i\} \right\} = \emptyset.
\]
Therefore, the number of reactions contained in the MAS of (31) is \(r = \sum_{p=0}^{\ell} r_p\).

In the following, we will expound that the Lyapunov Function PDEs induced by Com-\(\ell\)Sub1 MASs also work validly for stability analysis by generating a solution as the Lyapunov function.

**Lemma 20.** The stoichiometric subspace \(\mathcal{J}\) of a Com-\(\ell\)Sub1 MAS satisfies
\[
\mathcal{J} = \bigotimes_{p=0}^{\ell} \mathcal{J}^{(p)} \quad \text{and} \quad \dim \mathcal{J} = \sum_{p=0}^{\ell} \dim \mathcal{J}^{(p)} = \dim \mathcal{J}^{(0)} + \ell,
\]
where \(\mathcal{J}^{(p)}\) is the stoichiometric subspace of \(\{\mathcal{S}^{(p)}, \mathcal{C}^{(p)}, \mathcal{R}^{(p)}, \mathcal{K}^{(p)}\}\).

**Proof.** Since
\[
\mathcal{J} = \text{span} \left\{ \bigcup_{p=0}^{\ell} \bigcup_{i=1}^{r_p} \{v^{(p)}_i - v^{(p)}_i\} \right\}
\]
\[
= \sum_{p=0}^{\ell} \text{span} \left\{ \bigcup_{i=1}^{r_p} \{v^{(p)}_i - v^{(p)}_i\} \right\}
\]
\[
= \sum_{p=0}^{\ell} \left( \bigotimes_{q=0}^{p-1} \mathcal{O}_{n_q} \bigotimes_{q=p+1}^{\ell} \mathcal{O}_{n_q} \mathcal{J}^{(p)} \bigotimes_{q=0}^{p-1} \mathcal{O}_{n_q} \bigotimes_{q=p+1}^{\ell} \mathcal{O}_{n_q} \right)
\]
\[
= \sum_{p=0}^{\ell} \left( \bigotimes_{q=0}^{p-1} \mathcal{O}_{n_q} \bigotimes_{q=p+1}^{\ell} \mathcal{O}_{n_q} \mathcal{J}^{(p)} \bigotimes_{q=0}^{p-1} \mathcal{O}_{n_q} \bigotimes_{q=p+1}^{\ell} \mathcal{O}_{n_q} \right).
\]
we have \( \mathcal{J} = \bigotimes_{p=0}^{\ell} \mathcal{J}^{(p)} \) and \( \dim \mathcal{J} = \sum_{p=0}^{\ell} \dim \mathcal{J}^{(p)} = \dim \mathcal{J}^{(0)} + \ell \). Here, \( \bigoplus \) is the direct sum.

**Lemma 21.** For any state \( x \in \mathbb{R}_{\geq 0}^n \) of a Com-\( \ell \)Sub1 mass action system, if \( x \in \partial_{(x+\mathcal{J})}\cap\mathbb{R}_{>0}^n \) \( ((x+\mathcal{J})\cap\mathbb{R}_{>0}^n \neq \emptyset) \), then for \( \forall \ p \in \{0, \ldots, \ell \} \) we have \( x^{(p)} \in \mathbb{R}_{\geq 0}^n \) or \( x^{(p)} \in \partial_{(x^{(p)}+\mathcal{J}^{(p)})}\cap\mathbb{R}_{>0}^n \). Furthermore, there exists at least one \( q \in \{0, \ldots, \ell \} \) such that \( x^{(q)} \in \partial_{(x^{(q)}+\mathcal{J}^{(q)})}\cap\mathbb{R}_{>0}^n \).

**Proof.** Since \( (x+\mathcal{J})\cap\mathbb{R}_{>0}^n \neq \emptyset \), based on **Lemma 20**, we get

\[
(x+\mathcal{J})\cap\mathbb{R}_{>0}^n = \left( \bigotimes_{p=0}^{\ell} x^{(p)} + \bigotimes_{p=0}^{\ell} \mathcal{J}^{(p)} \right) \cap \left( \bigotimes_{p=0}^{\ell} \mathbb{R}_{>0}^n \right) = \bigotimes_{p=0}^{\ell} \left( x^{(p)} + \mathcal{J}^{(p)} \right) \cap \mathbb{R}_{>0}^n \neq \emptyset.
\]

Hence, \( (x^{(p)} + \mathcal{J}^{(p)}) \cap \mathbb{R}_{>0}^n \neq 0 \), i.e., \( x^{(p)} \in \mathbb{R}_{>0}^n \) or \( x^{(p)} \in \partial_{(x^{(p)}+\mathcal{J}^{(p)})}\cap\mathbb{R}_{>0}^n \) for \( \forall \ p \).

Besides, if \( x^{(p)} \in \mathbb{R}_{>0}^n \) for \( \forall \ p \), then \( x = \bigotimes_{p=0}^{\ell} x^{(p)} \in \mathbb{R}_{>0}^n \), which contradicts with the condition \( x \in \partial_{(x+\mathcal{J})}\cap\mathbb{R}_{>0}^n \). Thus, there exists at least one \( q \in \{0, \ldots, \ell \} \) such that \( x^{(q)} \in \partial_{(x^{(q)}+\mathcal{J}^{(q)})}\cap\mathbb{R}_{>0}^n \).

**Corollary 22.** For any boundary point \( \bar{x} \in \partial_{(\bar{x}+\mathcal{J})}\cap\mathbb{R}_{>0}^n \) \( ((\bar{x}+\mathcal{J})\cap\mathbb{R}_{>0}^n \neq \emptyset) \) of a Com-\( \ell \)Sub1 MAS, there exists an index set \( \mathbb{P}_{\bar{x}} \subseteq \{0, \ldots, \ell \} \) such that if \( p \in \mathbb{P}_{\bar{x}} \) then \( x^{(p)} \in \partial_{(x^{(p)}+\mathcal{J}^{(p)})}\cap\mathbb{R}_{>0}^n \), which is denoted by \( \bar{x}^{(p)} \) in the following.

**Lemma 23.** For a Com-\( \ell \)Sub1 MAS, let \( \bar{x} \) represent any boundary point of any positive stoichiometric compatibility class, the naive boundary complex set of \( \bar{x} \) is

\[
\bar{C}_{\bar{x}} = \bigcup_{p \in \mathbb{P}_{\bar{x}}} \left\{ \bigotimes_{q=0}^{p-1} 0_{n_q} \bigotimes_{q=p+1}^\ell \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell z \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell 0_{n_q} \bigotimes_{q=p}^\ell 0_{n_q} | z \in \bar{C}^{(p)}_{\bar{x}(p)} \right\} \bigcup_{p \notin \mathbb{P}_{\bar{x}}} \left\{ \bigotimes_{q=0}^{p-1} 0_{n_q} \bigotimes_{q=p+1}^\ell \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell z \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell 0_{n_q} \bigotimes_{q=p}^\ell 0_{n_q} | z \in C^{(p)} \right\},
\]

where \( \bar{C}^{(p)}_{\bar{x}(p)} \) is the naive boundary complex set of \( \bar{x}^{(p)} \) for \( (S^{(p)}, C^{(p)}, R^{(p)}, K^{(p)}) \).

**Proof.** According to the definition of the naive boundary complex set in (20), the one for the Com-\( \ell \)Sub1 MAS is

\[
\bar{C}_{\bar{x}} = \bigcup_{p=0}^{\ell} \left\{ v^{(p)}_i | \forall \{j\}_1^n, \exists \epsilon > 0, x_j \geq \epsilon v^{(p)}_j \right\} \bigcup \left\{ v^{(p)}_i | \forall \{j\}_1^n, \exists \epsilon > 0, x_j \geq \epsilon v^{(p)}_j \right\} = \bigcup_{p=0}^{\ell} \left\{ \bigotimes_{q=0}^{p-1} 0_{n_q} \bigotimes_{q=p+1}^\ell \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell 0_{n_q} \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell 0_{n_q} \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell 0_{n_q} | z \in \bar{C}^{(p)}_{\bar{x}(p)} \right\} \bigcup_{p \notin \mathbb{P}_{\bar{x}}} \left\{ \bigotimes_{q=0}^{p-1} 0_{n_q} \bigotimes_{q=p+1}^\ell \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell z \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell 0_{n_q} \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell 0_{n_q} \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell 0_{n_q} \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell 0_{n_q} \bigotimes_{q=p}^\ell 0_{n_q} \bigotimes_{q=p+1}^\ell 0_{n_q} \bigotimes_{q=p}^\ell 0_{n_q} | z \in C^{(p)} \right\}.
\]
Therefore, the result is true.

Lemma 24. For a Com-$\ell$Sub1 MAS, if the boundary complex set is chosen as the naive one given in Lemma 23, the Lyapunov Function PDEs are

\begin{equation}
\sum_{p=0}^{\ell} \left( \sum_{i=1}^{r_p} \Theta_1(i, p) - \sum_{i=1}^{r_p} \Theta_2(i, p) \right) = 0
\tag{35}
\end{equation}

and

\begin{equation}
\sum_{p \in \mathbb{F}_x} \lim_{x^{(p)} \to x^{(p)}_+} \left( \sum_{i=1}^{r_p} \Theta_1(i, p) - \sum_{i=1}^{r_p} \Theta_2(i, p) \right) + \sum_{p \not\in \mathbb{F}_x} \left( \sum_{i=1}^{r_p} \Theta_1(i, p) - \sum_{i=1}^{r_p} \Theta_2(i, p) \right) = 0,
\tag{36}
\end{equation}

where

\[ \Theta_1(i, p) = k_i^{(p)} x^{(p)} v_i^{(p)}, \quad \Theta_2(i, p) = k_i^{(p)} x^{(p)} v_i^{(p)} \exp \left\{ (v_i^{(p)} - v_i^{(p)})^\top \frac{\partial f(x)}{\partial x^{(p)}} \right\}, \]

\[ x = \bigotimes_{q=0}^{\ell} x^{(q)} \in \mathbb{R}_+^n, \text{ and } \bar{x} \text{ represents any boundary point of any positive stoichiometric compatibility class.} \]

Proof. Referring to the Lyapunov Function PDE of (15), we can write the version for the case of a Com-$\ell$Sub1 MAS to be

\[ \sum_{p=0}^{\ell} \left( \sum_{i=1}^{r_p} k_i^{(p)} x_i^{(p)} - \sum_{i=1}^{r_p} k_i^{(p)} x_i^{(p)} \exp \left\{ (v_i^{(p)} - v_i^{(p)})^\top \nabla f(x) \right\} \right) = 0. \]

Since \( x = \bigotimes_{q=0}^{\ell} x^{(q)} \in \mathbb{R}_+^n \) and \( v_i^{(p)} = \bigotimes_{q=0}^{p-1} 0_{n_q} \bigotimes v_i^{(p)} \bigotimes_{q=p+1}^{\ell} 0_{n_q} \), we have

\[ x_i^{(p)} = \left( \bigotimes_{q=0}^{\ell} x_i^{(q)} \right) \bigotimes_{q=0}^{p} 0_{n_q} \bigotimes v_i^{(p)} \bigotimes_{q=p+1}^{\ell} 0_{n_q} = x_i^{(p)} v_i^{(p)}. \]

Also, we have

\[ (v_i^{(p)} - v_i^{(p)})^\top \nabla f(x) = \left( \bigotimes_{q=0}^{p-1} 0_{n_q} \bigotimes (v_i^{(p)} - v_i^{(p)})^\top \bigotimes_{q=p+1}^{\ell} 0_{n_q} \right) \bigotimes \left( \bigotimes_{q=0}^{\ell} \frac{\partial f(x)}{\partial x^{(p)}} \right) \]

\[ = (v_i^{(p)} - v_i^{(p)})^\top \frac{\partial f(x)}{\partial x^{(p)}}. \]

Hence, we get (35).

By choosing (34) as the boundary complex set and referring to (19), we can write the boundary condition for the Lyapunov function PDE (35) to be (36).
Clearly, the Lyapunov Function PDEs (35) and (36) for a Com-ℓSub1 MAS are a combination of those PDEs of all sub-systems \((S^{(p)}, C^{(p)}, R^{(p)}, K^{(p)})^{ℓ}_{p=0}\). An immediate idea is to set a solution of the current Lyapunov Function PDEs also as a combination of the solutions obtained from the Lyapunov Function PDEs of all sub-systems.

**Theorem 25.** For a Com-ℓSub1 mass action system, the sub-system \((S^{(0)}, C^{(0)}, R^{(0)}, K^{(0)})\) is assumed to admit a positive complex balanced equilibrium while every other sub-system \((S^{(p)}, C^{(p)}, R^{(p)}, K^{(p)})\) \((p = 1, \cdots, ℓ)\) is supposed to have a positive equilibrium. Further let every sub-network from \(p = 1 \text{ to } ℓ\) possess the naive boundary complex set \(\tilde{\Sigma}_{x(p)}\) as the respective boundary complex set, and also, \(\tilde{\Sigma}_{x(p)} = \emptyset\) or \(\tilde{\Sigma}_{x(p)}\) includes at least a reactant complex and a resultant complex. Then the Lyapunov Function PDEs (35) and (36) for this Com-ℓSub1 MAS admit a twice continuous differentiable solution in the form of

\[
(37) \quad f(x) = \sum_{p=0}^{ℓ} f_p(x^{(p)}),
\]

where \(x = \bigotimes_{p=0}^{ℓ} x^{(p)} \in \mathbb{R}_{>0}^n\), and \(f_p(x^{(p)})\) is a solution defined by (11) in case of \(p = 0\) and by (29) in case of others \(p\) for the Lyapunov Function PDEs of every sub-network \((S^{(p)}, C^{(p)}, R^{(p)}, K^{(p)})\).

**Proof.** According to Theorems 11 and 18, under the known conditions the Lyapunov Function PDEs of every sub-system included in the Com-ℓSub1 MAS have a twice continuous differentiable solution defined by (11) in case of \(p = 0\) and (29) in case of others \(p\) in the area \(\mathbb{R}_{>0}^n\). Denote these solutions by \(f_p(x^{(p)})\) from \(p = 0\) to \(ℓ\) respectively, and further substitute each one into the corresponding Lyapunov Function PDEs, then we get

\[
\sum_{i=1}^{r_p} k_i^{(p)} x_i^{(p)} v_{i,(p)} - \sum_{i=1}^{r_p} k_i^{(p)} x_i^{(p)} v_{i,(p)} \exp \left\{ (v_{i,(p)} - v_{i,(p)})^\top \nabla f_p(x^{(p)}) \right\} = 0.
\]

Combining the sum of these equations from \(p = 0\) to \(ℓ\) and the fact that \(f(x) = \sum_{p=0}^{ℓ} f_p(x^{(p)})\) leads to \(\frac{\partial f(x)}{\partial x^{(p)}} = \nabla f_p(x^{(p)})\) will yield the current \(f(x)\) with \(x = \bigotimes_{p=0}^{ℓ} x^{(p)} \in \mathbb{R}_{>0}^n\) satisfying the Lyapunov Function PDE of (35).

Consider any boundary point \(\bar{x}\) of any positive stoichiometric compatibility class for this network system. According to Corollary 22, there exists a nonempty \(\mathbb{P}_x \subseteq \{0, \cdots, ℓ\}\) so that when \(p \in \mathbb{P}_x\) the pth entry of \(\bar{x}\) is a boundary point of a certain positive stoichiometric compatibility class of the sub-system \((S^{(p)}, C^{(p)}, R^{(p)}, K^{(p)})\). For those \(p \in \mathbb{P}_x\) since \(f_p(x^{(p)})\) satisfies the boundary condition (25), we have

\[
\lim_{x^{(p)} \to \bar{x}^{(p)}} \sum_{x^{(p)} \in \mathbb{P}_x^{(p)} \cap \mathbb{R}_{>0}^n} \Theta_1(i, p) - \sum_{x^{(p)} \in \mathbb{P}_x^{(p)} \cap \mathbb{R}_{>0}^n} \Theta_2(i, p) = 0.
\]

Namely, the first term in the left hand of (36) is equal to 0. The second term is also equal to 0 since for those \(p \notin \mathbb{P}_x\) every \(f_p(x^{(p)})\) supports the Lyapunov function (15). This completes the proof.
Lemma 26. A state $x^* = \bigotimes_{p=0}^{\ell} x^{(p)*} \in \mathbb{R}^{n_0}_{>0}$ is a positive equilibrium of a Com-$\ell$Sub1 MAS if and only if for any $p = 1, \ldots, \ell$, $x^{(p)*} \in \mathbb{R}^{n_p}_{>0}$ is a positive equilibrium of the sub-system $(\mathcal{S}^{(p)}, \mathcal{C}^{(p)}, \mathcal{R}^{(p)}, \mathcal{K}^{(p)})$.

Proof. The result is immediate by inserting the state $x^* = \bigotimes_{p=0}^{\ell} x^{(p)*} \in \mathbb{R}^{n_0}_{>0}$ into the dynamics of the Com-$\ell$Sub1 MAS (32).

Theorem 27. For any $\ell \geq 1$, consider a Com-$\ell$Sub1 mass action system with the sub-system $(\mathcal{S}^{(0)}, \mathcal{C}^{(0)}, \mathcal{R}^{(0)}, \mathcal{K}^{(0)})$ admitting a complex balanced equilibrium $x^{(0)*} \in \mathbb{R}^{n_0}_{>0}$ and other sub-systems $(\mathcal{S}^{(p)}, \mathcal{C}^{(p)}, \mathcal{R}^{(p)}, \mathcal{K}^{(p)})_{p=1}^{\ell}$ respectively admitting an equilibrium $x^{(p)*} \in \mathbb{R}^{n_p}_{>0}$. Also, for any sub-system $(\mathcal{S}^{(p)}, \mathcal{C}^{(p)}, \mathcal{R}^{(p)}, \mathcal{K}^{(p)})$ $(p \in \{1, \ldots, \ell\})$ the boundary complex set is chosen as the naive boundary complex set $\overline{\mathcal{C}}^{(p)}_{2^{(p)}}$ defined by (20), and $\overline{\mathcal{C}}^{(p)}_{2^{(p)}} = \emptyset$ or $\overline{\mathcal{C}}^{(p)}_{2^{(p)}}$ includes both reactant complexes and resultant complexes. If for all $\{p\}_{1}^{\ell}$ the conditions

$$w_p^\top \frac{\partial}{\partial x^{(p)}} g_p(x^{(p)}, 1) \bigg|_{x^{(p)} = x^{(p)*}} < 0$$

are true, then the Lyapunov Function PDEs induced by this Com-$\ell$Sub1 MAS are able to produce a solution (37) as a Lyapunov function serving for analyzing the local asymptotic stability of the network system. Here, $w_p \in \mathbb{R}^{n_p} \setminus \{0_{n_p}\}$ is a set of bases of $\mathcal{S}^{(p)}$ and $g_p(x^{(p)}, u)$ is defined according to (27).

Proof. From Lemma 26, since all sub-systems included in the Com-$\ell$Sub1 MAS have an equilibrium $x^{(p)*} \in \mathbb{R}^{n_p}_{>0}$ $(\forall p \in \{0, \ldots, \ell\})$, the Com-$\ell$Sub1 MAS admits a positive equilibrium $x^* = \bigotimes_{p=0}^{\ell} x^{(p)*} \in \mathbb{R}^{n_0}_{>0}$. Further from Theorem 25, $f(x) = \sum_{p=0}^{\ell} f_p(x^{(p)})$ defined by (37) is a twice continuous differentiable solution of the Lyapunov Function PDEs (35) plus (36). From the condition of $w_p^\top \frac{\partial}{\partial x^{(p)}} g_p(x^{(p)}, 1) \bigg|_{x^{(p)} = x^{(p)*}} < 0$ and the continuity of $g(x, u)$ with respect to $u$, there exist neighbourhoods of $x^{(p)*}$, denoted as $\delta(x^{(p)*})$ $(p = 1, \ldots, \ell)$, such that for all $x^{(p)} \in \delta(x^{(p)*})$ we have

$$w_p^\top \frac{\partial}{\partial x^{(p)}} g_p(x^{(p)}, \tilde{u}^{(p)}(x^{(p)})) < 0,$$

where $\tilde{u}^{(p)}(x^{(p)})$ makes $g_p(x^{(p)}, u) = 0$. Hence, let $\mu = \bigotimes_{p=0}^{\ell} \mu^{(p)} \in \mathcal{S}$ then for any $x \in \{R_{>0}^{n_0} \bigotimes_{p=1}^{\ell} \delta(x^{(p)*})\} \cap (x^* + \mathcal{S}) \cap R_{>0}^{n_0}$ we get

$$\mu^\top \nabla^2 f(x) \mu = \mu^{(0)}^\top \mathrm{diag}\left\{1/x^{(0)}_1, \ldots, 1/x^{(0)}_{n_0}\right\} \mu^{(0)} + \sum_{p=1}^{\ell} (\mu^{(p)})^\top w_p^2 \cdot \frac{-w_p^\top \frac{\partial}{\partial x^{(p)}} g_p(x^{(p)}, \tilde{u}^{(p)}(x^{(p)})) / \partial \mu^{(p)} g_p(x^{(p)}, \tilde{u}^{(p)})}{\tilde{u}(x^{(p)})} \geq 0.$$

Clearly, the above equality holds if and only if $\mu = 0_{n}$. This means that all conditions in Theorem 10 are satisfied, and the result is thus shown.
Example 4. Consider a Com-$\ell$Sub1 MAS ($\ell = 1$) with the reaction route following

\begin{equation}
\begin{array}{c}
S_1^{(0)} \xrightarrow{k_1^{(0)}} S_2^{(0)} \\
S_1^{(0)} \xrightarrow{k_2^{(0)}} S_2^{(0)} \\
S_1^{(1)} \xrightarrow{k_1^{(1)}} S_2^{(1)} \\
2S_2^{(1)} \xrightarrow{k_2^{(1)}} 2S_1^{(1)}.
\end{array}
\end{equation}

The sub-system $(S^{(0)}, C^{(0)}, R^{(0)}, K^{(0)})$ is complex balanced that has complexes as

\[ v_{1(0)} = v'_{3(0)} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \quad v_{2(0)} = v'_{1(0)} = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \quad v_{3(0)} = v'_{2(0)} = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \]

and admits a complex balanced equilibrium $x^{(0)*} = (k_2^{(0)}k_3^{(0)}k_1^{(0)}k_2^{(0)})^T$. In addition, the sub-system $(S^{(1)}, C^{(1)}, R^{(1)}, K^{(1)})$ (the same as in Example 2) is of 1-dimensional stoichiometric subspace with complexes

\[ v_{1(1)} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad v'_{1(1)} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad v_{2(1)} = \begin{pmatrix} 0 \\ 2 \end{pmatrix}, \quad v'_{2(1)} = \begin{pmatrix} 2 \\ 0 \end{pmatrix} \]

and an equilibrium $x^{(1)*} = \left(2k_2^{(1)}, \sqrt{k_1^{(1)}} \right)^T$. Moreover, the naive boundary complex set is set as

\[ \bar{C}_{x^{(1)}} = \left\{ \begin{array}{l}
(v_{1(1)}, v'_{2(1)}) \quad \text{with } \bar{x}_{1(1)} > 0; \\
(v_{2(1)}, v'_{1(1)}) \quad \text{with } \bar{x}_{2(1)} > 0.
\end{array} \right. \]

By Theorem 25, there exists a solution supporting the Lyapunov Function PDEs induced from this Com-$\ell$Sub1 MAS, written as

\[ f(x) = f_0(x^{(0)}) + f_1(x^{(1)}), \]

where $x^{(0)} = (x_{1(0)}, x_{2(0)}, x_{3(0)})^T$, $x^{(1)} = (x_{1(1)}, x_{2(1)})^T$, $x = x^{(0)} \otimes x^{(1)}$,

\[ f_0(x^{(0)}) = x^{(0)}\ln \left( \frac{x^{(0)}}{x^{(0)*}} \right) - 3^T (x^{(0)} - x^{(0)*}) \]

and

\[ f_1(x^{(1)}) = \int_0^{\gamma(x^{(1)})} \frac{1}{2} \left( \frac{k_2^{(1)}}{k_1^{(1)}} \bar{y}^{2(1)} + \sqrt{\left( \frac{k_2^{(1)}}{k_1^{(1)}} \right)^2 \bar{y}^{2(1)} + 4k_1^{(1)}k_2^{(1)} \bar{y}^{2(1)} + k_1^{(1)}k_2^{(1)} \bar{y}^{2(1)}} \right) d\tau. \]

In the above equation, $\bar{y} = \bar{y}^T (x^{(1)}) + \tau w_1$ and

\[ \bar{y}^T (x^{(1)}) = \frac{1}{2} \left( \frac{1}{2} \frac{1}{2} \right) x^{(1)}, \quad \gamma(x^{(1)}) = \frac{w_1^T x^{(1)}}{2}, \quad w_1 = (-1, 1)^T. \]
Further, from $g_1(x^{(1)}, u) = k_1^{(1)} x_{1(1)} - k_2^{(1)} (x_{2(1)})^2 u^{-1} - k_2^{(1)} (x_{2(1)})^2 u^{-2}$ we have

$$w_1^\top \frac{\partial}{\partial x^{(1)}} g_1 \left( x^{(1)}, u \right) \bigg|_{x^{(1)} = x^{(1)*}} = -k_1^{(1)} - 4k_2^{(1)} x_{2(1)*}^2 < 0.$$ 

Therefore, based on Theorem 27, $f(x)$ is an available Lyapunove function for the given Complex Sub1 CRN and could suggest its equilibrium $(x^{(0)*}, x^{(1)*})^\top$ to be locally asymptotically stable.

6.2. Other Two Special CRNs with $\dim \mathcal{S} \geq 2$.

Example 5. Consider a CRN of the form

$$2S_1 \xrightarrow{k_1} S_1 + S_2, \quad 2S_2 \xrightarrow{k_2} S_2 + S_3, \quad 2S_3 \xrightarrow{k_3} S_3 + S_1.$$ 

We have the species set $\mathcal{S} = \{ S_1, S_2, S_3 \}$, complex set $\mathcal{C} = \{ v_1, v_1', v_2, v_2', v_3, v_3' \}$, reaction set $\mathcal{R} = \{ v_1 \rightarrow v_1', v_2 \rightarrow v_2', v_3 \rightarrow v_3' \}$ and kinetic set $\mathcal{K} = (k_1, k_2, k_3)$, where

$$v_1 = \begin{pmatrix} 2 \\ 0 \\ 0 \end{pmatrix}, \quad v_1' = \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}, \quad v_2 = \begin{pmatrix} 0 \\ 2 \\ 0 \end{pmatrix}, \quad v_2' = \begin{pmatrix} 0 \\ 1 \\ 2 \end{pmatrix}, \quad v_3 = \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}, \quad v_3' = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix},$$

By the mass-action kinetics, the dynamics of the system is expressed as

$$\dot{x}(t) = \sum_{i=1}^{3} k_i x_i v_i^{(i)} (v_i' - v_i), \quad x \in \mathbb{R}^{n}_{>0}.$$ 

Therefore, we have $\dim \mathcal{S} = \dim \text{span}(v_i' - v_i, v_i' - v_i, v_i' - v_i) = 2$. Obviously, this network does not belong to any type of CRNs mentioned above. However, it has some special properties.

Lemma 28. In every positive stoichiometric compatibility class induced by any given $\tilde{x} \in \mathbb{R}^{n}_{>0}$ and the stoichiometric subspace $\mathcal{S}$ of the MAS governed by (39), any state $x$ of this MAS is constrained by $\mathbf{1}_{3}^\top x = \mathbf{1}_{3}^\top \tilde{x}$.

Proof. From $\mathcal{S} = \text{span}(v_i' - v_i, v_i' - v_i, v_i' - v_i)$, we have that the orthogonal complement space $\mathcal{S}^\perp$ of $\mathcal{S}$ is of one dimension, and $(1, 1, 1)^\top$ can act as a set of bases of $\mathcal{S}^\perp$, i.e., $(1, 1, 1)^\top \perp \mathcal{S}$. Therefore, for every positive stoichiometric compatibility class $(\tilde{x} + \mathcal{S}) \cap \mathbb{R}^{n}_{>0}$ induced by any given $\tilde{x} \in \mathbb{R}^{n}_{>0}$ and $\mathcal{S}$, the state $x$ of the MAS satisfies $x - \tilde{x} \in \mathcal{S}$, i.e., $(x - \tilde{x}) \perp (1, 1, 1)^\top$. We get $\mathbf{1}_{3}^\top x = \mathbf{1}_{3}^\top \tilde{x}$. 

Lemma 29. The MAS governed by (39) admits a unique equilibrium in each positive stoichiometric compatibility class. Furthermore, this sole equilibrium, denoted by $x^* \in \mathbb{R}^{3}_{>0}$, satisfies $\sqrt{k_1 x_1^*} = \sqrt{k_2 x_2^*} = \sqrt{k_3 x_3^*}$.

Proof. Let $(\tilde{x} + \mathcal{S}) \cap \mathbb{R}^{n}_{>0}$ represent any positive stoichiometric compatibility class in which the state of the MAS following (39) evolves. If the equilibrium $x^* \in \mathbb{R}^{3}_{>0}$ exists, then it must satisfy

$$\mathbf{1}_{3}^\top x^* = \mathbf{1}_{3}^\top \tilde{x} \quad \text{and} \quad k_1 (x_1^*)^2 = k_2 (x_2^*)^2 = k_3 (x_3^*)^2.$$
Denote
\[
K = \begin{pmatrix}
1 & 1 & 1 \\
\sqrt{k_1} & -\sqrt{k_2} & 0 \\
\sqrt{k_1} & 0 & -\sqrt{k_3}
\end{pmatrix},
\]
then the above two relations can be integrated together and rewritten as
\[
Kx^* = 1^\top \tilde{x}.
\]
Since \(\det(K) = \sqrt{k_1k_2} + \sqrt{k_2k_3} + \sqrt{k_1k_3} \neq 0\), \(x^*\) exists and is also unique in \((\tilde{x} + \mathcal{S}) \cap \mathbb{R}_{>0}^n\). Furthermore, \(x^*\) supports the relation \(\sqrt{k_1}x^*_1 = \sqrt{k_2}x^*_2 = \sqrt{k_3}x^*_3\), and
\[
x^* = \frac{1^\top \tilde{x}}{\sqrt{k_1k_2} + \sqrt{k_2k_3} + \sqrt{k_1k_3}} \left(\sqrt{k_2k_3}, \sqrt{k_1k_3}, \sqrt{k_1k_2}\right)^\top.
\]

Based on these two properties, it is not difficult to find a solution for the Lyapunov function PDEs (15) and (19) of this MAS.

**Theorem 30.** For the MAS described by (39), if the boundary complex set \(\mathcal{C}_{\tilde{x}}\) is set to be empty, then the Lyapunov function PDEs (15) and (19) generated by this MAS admit a solution
\[
(40) \quad f(x) = 2x^\top \text{Ln} \left(\frac{x}{x^*}\right) - 21^\top_3 (x - x^*),
\]
where \(x^* \in \mathbb{R}_{>0}^3\) is an equilibrium of the MAS under consideration. Moreover this solution can behave as the Lyapunov function to suggest the MAS locally asymptotically stable at \(x^*\).

**Proof.** Substituting \(\nabla f(x) = 2\text{Ln} \left(\frac{x}{x^*}\right)\) into the L.H.S. of (15) yields
\[
\text{L.H.S of Eq. (15)} = k_1 x^2_1 + k_2 x^2_2 + k_3 x^2_3 - k_1 \left(\frac{x^*_1}{x_1}\right)^2 \frac{x^2_1}{x_1} - k_2 \left(\frac{x^*_2}{x_2}\right)^2 \frac{x^2_2}{x_2} - k_3 \left(\frac{x^*_3}{x_3}\right)^2 \frac{x^2_3}{x_3} = 0.
\]
Hence, \(f(x) = 2x^\top \text{Ln} \left(\frac{x}{x^*}\right) - 21^\top_3\) is a solution of the PDE (15). In the meanwhile, the boundary condition of (19) is naturally true with \(\mathcal{C}_{\tilde{x}} = \emptyset\). Moreover, the Hessian matrix of \(f(x)\) is expressed as
\[
\nabla^2 f(x) = \begin{pmatrix}
\frac{2}{x_1} & \frac{2}{x_2} & \frac{2}{x_3} \\
\frac{2}{x_2} & \frac{2}{x_3} & \frac{2}{x_3}
\end{pmatrix}
\]
which is positive definite in \(\mathbb{R}_{>0}^n\). Hence, the condition (22) is satisfied for every state, and the asymptotic stability holds immediately from **Theorem 10**.

**Remark 5.** The solution \(f(x) = 2x^\top \text{Ln} \left(\frac{x}{x^*}\right) - 21^\top_3 (x - x^*)\) is actually a function similar to the pseudo-Helmholtz free energy function. It can be rewritten as \(f(x) = 2G(x)\).
Example 6. The second CRN has 3-dimensional stoichiometric subspace and is given by

\[ 3S_1 \xrightarrow{k_1} 2S_1 + S_2, \quad 2S_2 \xrightarrow{k_2} S_2 + S_3, \quad S_3 \xrightarrow{k_3} S_1, \quad 0 \xrightarrow{k_4} S_3, \quad \xrightarrow{k_5} 0 \]

with the complexes being

\[
\begin{align*}
v_1 &= \begin{pmatrix} 3 \\ 0 \\ 0 \end{pmatrix}, & v_1' &= \begin{pmatrix} 2 \\ 1 \\ 0 \end{pmatrix}, & v_2 &= \begin{pmatrix} 0 \\ 2 \\ 0 \end{pmatrix}, & v_2' &= \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}, & v_3 &= \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, & v_3' &= \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \\
v_4 &= v_5 = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}, & v_5 &= v_4' = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}.
\end{align*}
\]

By setting \( k_1 = k_2 = k_3 = k_4 = k_5 = 1 \) for simplicity, the dynamical equation follows

\[
\begin{align*}
\dot{x}_1(t) &= -x_3^3 + x_3, \\
\dot{x}_2(t) &= x_3^3 - x_2^2, \\
\dot{x}_3(t) &= x_2^2 - 2x_3 + 1
\end{align*}
\]

and the Lyapunov Function PDE is

\[
x_1^3 + x_2^2 + 2x_3 + 1 - x_1^3 \exp \left\{ -\frac{\partial f}{\partial x_1} + \frac{\partial f}{\partial x_2} \right\} - x_2^2 \exp \left\{ -\frac{\partial f}{\partial x_2} + \frac{\partial f}{\partial x_3} \right\} - x_3 \exp \left\{ \frac{\partial f}{\partial x_1} - \frac{\partial f}{\partial x_3} \right\} - \exp \left\{ -\frac{\partial f}{\partial x_3} \right\} - x_3 \exp \left\{ -\frac{\partial f}{\partial x_3} \right\} = 0.
\]

We choose the boundary complex to be empty set at any boundary point, then the boundary condition (19) vanishes.

It is not difficult to verify that the following function

\[ f(x) = 3(x_1 \ln x_1 - x_1) + 2(x_2 \ln x_2 - x_2) + (x_3 \ln x_3 - x_3) \]

is a solution of the above Lyapunov Function PDE. Moreover, this solution meets all conditions given in Theorem 10, so it can work for analyzing the asymptotic stability of the MAS.

6.3. Computational verification for a 2-dimensional CRN. The last CRN has the form

\[ 2S_1 \xrightarrow{k_1} S_2 \xrightarrow{k_2} S_1 + S_3 \xrightarrow{k_3} 0, \]

where the complexes are

\[
\begin{align*}
v_1 &= \begin{pmatrix} 2 \\ 0 \end{pmatrix}, & v_1' &= \begin{pmatrix} 0 \\ 1 \end{pmatrix}, & v_2 &= \begin{pmatrix} 0 \\ 1 \end{pmatrix}, & v_2' &= \begin{pmatrix} 1 \\ 0 \end{pmatrix}, & v_3 &= \begin{pmatrix} 0 \\ 0 \end{pmatrix}, & v_3' &= \begin{pmatrix} 1 \\ 0 \end{pmatrix}.
\end{align*}
\]

We also set \( k_1 = k_2 = k_3 = 1 \) for simplicity, and thus write the dynamics as

\[
\begin{align*}
\dot{x}_1(t) &= -2x_1^2 + x_2 + 1, \\
\dot{x}_2(t) &= x_2^2 - x_2.
\end{align*}
\]
Although this CRN looks simple and the dimension of its stoichiometric subspace is only 2, to our knowledge it is difficult to find a solution for its Lyapunov Function PDE

\[
\begin{align*}
x_1^2 + x_2 + 1 - x_1^2 \exp \left\{-2 \frac{\partial f}{\partial x_1} + \frac{\partial f}{\partial x_2} \right\} - x_2 \exp \left\{\frac{\partial f}{\partial x_1} - \frac{\partial f}{\partial x_2} \right\} - \exp \left\{\frac{\partial f}{\partial x_1} \right\} &= 0.
\end{align*}
\]

We thus try to make a computational verification for this example.

Note that \((x^*_1, x^*_2)^\top = (1, 1)^\top\) is the unique equilibrium in the network system, and there are three types of native boundary complex sets according to the boundary points considered, that is

\[
\bar{C}_\bar{x} = \begin{cases} 
\{(0, 0)^\top, (0, 1)^\top\}, & \bar{x} = (\bar{x}_1, 0)^\top \text{ with } \bar{x}_1 > 0; \\
\{(0, 0)^\top, (1, 0)^\top, (2, 0)^\top\}, & \bar{x} = (0, \bar{x}_2)^\top \text{ with } \bar{x}_2 > 0; \\
\{(0, 0)^\top\}, & \bar{x} = (0, 0)^\top.
\end{cases}
\]

In order to observe whether \(f(x)\) has the potential to act as the Lyapunov function, we make a Taylor expansion about it at the equilibrium \((1, 1)^\top\). For simplicity but without loss of generality, the expansion is made up to the third order. Fig. 1 exhibits the simulation results about \(f(x)\) in sub-figure (a) and about the minimum eigenvalue, denoted by \(\lambda_{\min}\), of its Hessian matrix in sub-figure (c). From the sub-figure (a) and the corresponding contours sub-figure (b), it is suggested that \(f(x)\) is convex with the minimum evaluated at the equilibrium. Further from the sub-figure (c) and the corresponding contours sub-figure (d), there exists a neighbourhood around the equilibrium in which \(f(x)\) is strictly convex. This indicates that \(f(x)\) meets all conditions requested in Theorem 10. Hence, the computational simulation also supports that the Lyapunov Function PDE method is valid.

7. Conclusion and a Conjecture. This paper is devoted to developing the Lyapunov function with clear physical meaning for stability analysis for chemical reaction networks. We have attempted to address this issue by establishing approximation from a microscopic concept of CRNs, the scaling non-equilibrium potential, to the macroscopic notation of the candidate Lyapunov function. After rewriting the Chemical Master Equation skillfully, we have succeeded in implementing the approximation and transformed the ODE into a PDE, which together with the developed boundary condition yields the Lyapunov Function PDEs. And then, we have proved that the solution (if exists) of the PDEs is dissipative, and thus has great potential to become a Lyapunov function. Next, we have applied the Lyapunov Function PDEs to complex-balanced CRNs and general CRNs with 1-dimensional stoichiometric subspace. For both cases, we construct their solutions that can act as Lyapunov functions rendering the respective system to be locally asymptotically stable. Finally, we have extended the applications of the Lyapunov Function PDEs to some special CRNs with more than 2-dimensional stoichiometric subspace, and showed that the PDEs also work validly for them in stability analysis.

Notwithstanding the performance illustrated by the Lyapunov Function PDEs is very encouraging, there are still some problems needed to be explored in the future. One of the most urgent problems is to prove that the Lyapunov Function PDEs CAN or CANNOT serve for general CRNs with more than 2-dimensional stoichiometric subspace. This may be an extremely arduous task, however, we are inclined to think they can. We summarize the proof
task as a conjecture: “For any mass action system that admits a stable positive equilibrium, if the boundary complex set is equipped properly, then the Lyapunov Function PDEs induced by this system have a solution qualified as a Lyapunov function to suggest the system to be locally asymptotically stable at the equilibrium.” The converse problem is also interesting, i.e., will all Lyapunov functions be solutions to the PDEs in some sense?
